4209. Nilsen, A. B. E. ..... Machinery for making casks.
4210. Redfern, G. F. ..... Flexible couplings for toothed wheel gearing (*Wolseley*).

10th March, 1891.

4216. Bush & Powers ..... Steam boilers.
4218. Richards & Cooley ..... Automatic grain-weighing and bagging machines.
4219. Melling, J. W. ..... Regulating and reversing gear for steam engines.
4220. Brown, A. E. ..... Friction clutches.
4222. Lanchester, F. W. ..... Gas engines.
4224. Spencer, G..... Friction clutches.
4229. Hirsch, R. ..... Apparatus for separating gases
4230. Lanchester, F. W. ..... Gas engine starting mechanism.
4231. Arundale & Cooper ... Pickers of looms.
4238. Luce, C. J. ..... Car brake and starter apparatus.
4250. Jensen, C. A..... Car couplers (*Gould*).
4268. Gray & Richter ..... Metal planing machines.
4283. Charnley, R. ..... Looms.
4289. Förste & Tromm ..... Ruling machines.
4301. Thompson, W. P. ..... Wire cutters (*Arnold*).
4302. Boult, A. J. ..... Hydraulic lifts (*Pifre*).
4303. Jarvis, G. A. ..... Blast machines.
4308. Caird & Rayner ..... Surface condensers.
4312. Craig, T. (of the Firm of Isaac Holden & Sons) Apparatus for preparing and combing wool.
4315. Thompson, W. H..... Crushing machinery.

11th March, 1891.

4319. Bell & Sauter ..... Apparatus for working ships' boats.
4322. Sharpe, W. H. ..... Railway chair.
4326. Lake & Crawshaw ..... Pneumatic hammers.
4327. Garstang, J. ..... Warp dressing machines.
4331. Barker, R. W. ..... Rolls for manufacturing car axles (*Evans*).
4340. The Gaseous and Liquid Fuel Supply Company, Ld. ..... Steam boiler furnaces.
4343. Ford, J. ..... Self-binding reaping machines.
4344. Cameron, M. H..... Machines for cropping and shearing various sections of iron bars, &c.
4345. Barker, G. ..... Carbonising and drying machine (*Cole & Pedder*).
4349. Mountain, R..... Brick-making machines.
4355. Campbell, H. ..... Gas engines.
4357. Robertson, E. J. ..... Railway chair and fish plate combined.
4359. Brown, D. ..... Apparatus for making wood screws.
4360. Munns, W. H. ..... Driving mechanism for elevators (*Reedy*).
4363. Munns, W. H..... Apparatus for washing barrels (*Bidwell*).
4370. Krüger, R. O. ..... Printing machines.
4386. Inwood, C. ..... Rotary fans.
4395. Siemens Brothers & Co., Ld. ..... Shaft couplings (*Siemens & Halske*).
4400. Lake, H. H. ..... Brush-making machines (*Flematti*).
4402. Hopkinson & Hopkinson Valves for steam boilers.
4403. Boult, A. J. ..... Air pumps (*Reinmann, Dittmar, & Falkenhausen*).
4411. Horn, W. W. ..... Valves (*Kelly & Jenckes*).

12th March, 1891.

4438. Wilson, A. ..... Marine engine governor.
4450. Atkinson, J. ..... Pumps for vapours.
4461. Kosinski & Kisielnicki Steam boilers.
4473. Hopkinson & Hopkinson Safety valves.
4481. Redfern, G. F. ..... Car couplings (*Luard & Lindsley*).
4488. Gessner, E..... Condensers for carding engines. (4th September, 1890.)
4489. Basset, W. B..... Ordnance.

13th March, 1891.

4495. Livesey, Sen., & Livesey, Jun. ..... Looms.
4496. Renold, H. ..... Chain gearing.
4498. Hoyle & Dobson ..... Ring spinning or doubling frames.
4500. Jones, F. J..... Gas purifiers.
4505. Rigby, W. F. ..... Tools for making steel wire file-cleaning brushes.
4512. Stant, J. ..... Water motors.
4522. Huelser, C. ..... Brick presses (*Mühlenbauanstalt, Machinenfabrik and Eisengiesserei, vorm., Gébr. Seck*).
4524. Bayer, R..... Rotary slide valve for steam and other engines.
4535. Griffin, S. ..... Gas engine governor.
4542. Longridge, Cawley, & Austin..... Fluid pressure engines.
4549. May, W. E. ..... Apparatus for casting and working metals.

14th March, 1891.

4559. Parker, J. H..... Apparatus for dyeing fabrics.
4560. Parker, J. H..... Apparatus for dyeing woven fabrics.
4561. Reader, W..... Rotary colour printing machine.
4563. Wells, C. ..... Steam engines.
4580. Royston, E. R. ..... Valve seats for double poppet-valves (*Barclay*).
4581. Stewart, G. ..... Water gauge cocks.
4585. Thornton, T. ..... Railway chairs and keys.
4591. Lyall, J. ..... Steam boilers.
4618. Cauderay, J. ..... Air and vapour meter.

ELECTRICITY.

12th March, 1891.

1051A. De Ferranti, S. Z. ... Testing electrical transformers and dynamos. (20th January, 1891.)

9th March, 1891.

4170. Willatt, W. H..... Electrical distribution.

10th March, 1891.

4214. Bennett & Hides ..... Telephones.
4215. Macdonald & Dodd..... Automatic electrical block signalling on railways.
4235. Fletcher, G. E..... Telegraphic transmitter.
4256. Nash, F. J. ..... Insulation of electric conductors.
4259. Lake, H. H..... Electric motors (*The Giant Electric Motor Company*).
4263. Wright & Wilson ..... Preventing induction in telephones.
4269. Nash, F. J. ..... Insulated electric wires.
4271. Newton, P. A. ..... Railway signalling (*The American Electric Railway Signal Company*).
4306. Boggett, W. ..... Dynamos.

11th March, 1891.

4367. Munns, W. H..... Signal and search light lantern (*Martin & Knight*).
4410. Horn, W. W. ..... Telephone enunciator (*Lawrence & Oakwood*).

12th March, 1891.

4479. Morgan-Grenville, L. F. H. C. ..... Insulating underground conductors.
4482. Prickett, C. J. ..... Telephonic switch boards.

13th March, 1891.

4554. Redfern, G. F. ..... Armatures for electrical machinery (*W. Lahmeyer & Co.*).

14th March, 1891.

4583. Perry, J. ..... Electric supply meters.

CHEMISTRY.

9th March, 1891.

4184. Wilson, F. ..... Method of treating picric acid as an explosive.

10th March, 1891.

4243. Chancellor, C. W. ..... Method of and apparatus for treating sewage.

11th March, 1891.

4396. Strap, J. ..... Separation of copper, nickel, and silver from matts.

12th March, 1891.

4487. Ancizar, R. ..... Manufacture of sulphate of quinine (*Zerda-Bayon*).

13th March, 1891.

4547. Anderson & Brand ..... Manufacture of carbonates of sodium and potassium and of chlorine.

MISCELLANEOUS.

9th March, 1891.

4152. Russell, H..... Valves for taps and pipes.
4156. Rhodes, G. G..... Method of constructing web cranks for steam engines.
4186. Hickton, R. J. ..... Means for preventing driving belts from slipping.

10th March, 1891.

4236. Bate, C. McG. ..... Spanners.
4244. Clarke, F. J. ..... Preventing incrustation in steam boilers.

11th March, 1891.

4350. Randle, C. O..... Boat lowering apparatus.
4384. Von Ehrenwerth, J. ... Manufacture of iron and steel.
4388. Napier, J. M..... Speed indicators.

12th March, 1891.

4418. Taylor, J. W. ..... Milling and grinding of radius and other circular cutters.

14th March, 1891.

4613. Silverman, L. ..... Manufacture of tubes for boilers.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Engine Governors.—*J. H. Dales, Leeds.*—In the accompanying illustrations, Fig. 1 is an elevation showing the apparatus for the above purpose, Figs. 2 and 3 being front and side elevations respectively of an enlarged detail thereof. Referring to Figs. 2 and 3, a spring A is stretched between a lug B, which is placed on the bracket arm C of the governor head, and a similar lug B¹, which is placed on the ball arm D of the governor. This spring is placed in the line of the resultant of the parallelogram of forces

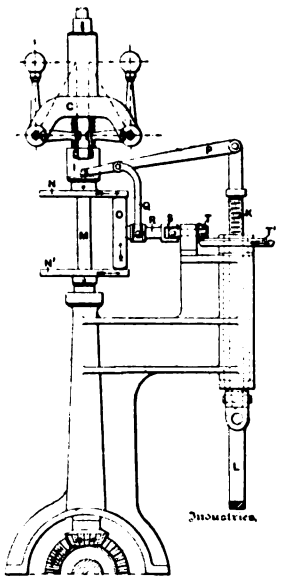

FIG. 1

shown in dotted lines, and is duplicated on the opposite side of the centre line of the ball arm D. A shaft E is passed through the ball arm D and secured therein, and the outer ends of the shaft E project clear through holes in the bracket arms C of the governor, so as not to touch the said holes. Slots are provided in the spindle E for the springs A to stretch through, but quite freely. Between the projecting ends of the spindle E and lugs F a second set of springs G are stretched, one on each outer side of the bracket arms C. These springs are in tension when the governor is working, and they counteract the centrifugal force of the governor arms generally, as distinguished from the lever action of the governor arms. The horizontal limbs H of the governor arms are connected to the slider I by means of flat springs J. Referring to Fig. 1, I is connected to the differential lever P, carrying on its outer end the controlling screw K connected at its lower end to the valve connecting rod L. The governor spindle or shaft M carries and drives a pair of friction discs N N¹, in contact with either of which the friction wheel O may be placed by the action of the governor through the lever P and connecting link Q, thus imparting rotary motion to the shaft R, "Hooks" joint S, and bevel gear T T¹, which is mounted and fixed on the head of the long nut of the controlling screw K. Assuming that the shaft M is driven in the direction of the arrow, the governor, in performing its functions, raises or lowers the shaft R, and thus places the friction wheel O in contact with one

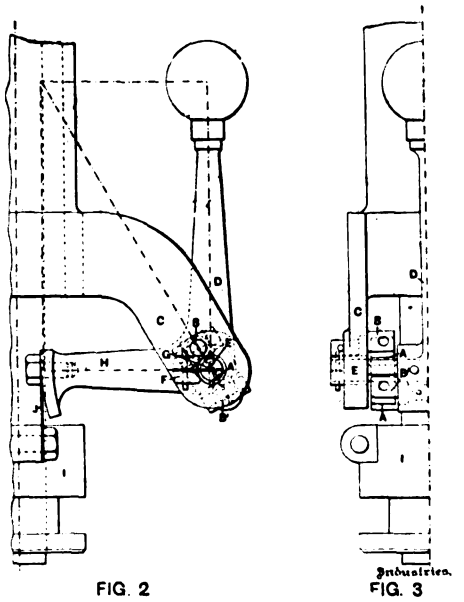

FIG. 2

FIG. 3

of the rotating discs N or N¹, which produces a motion of the screw K in the opposite direction to that of the governor slider I, and in so doing takes off the friction pressure of the friction wheel from the disc with which it was in contact, and the further motion of the screw K consequently ceases. If the screw by any means should over-act it places the friction wheel O in contact with the opposite disc, which will reverse the over-action of the screw. Five claims are made, embracing the engine governing apparatus substantially as described, and also the combination therewith of a differential pressure apparatus as described in a prior patent, No. 14216 of 1888.—No. 2703. February 19th, 1890. 8*d*.

Veneer Cutting Machinery.—*G. A. Oncken, Chicago, Illinois, U.S.A.*—A machine for the above purpose is shown in the annexed illustrations, of which Fig. 1 is a part sectional plan, Fig. 2 a front sectional elevation, and Fig. 3 a transverse section of Fig. 2. The presser-bar A is attached to a slide B guided in the frame C by means of two bars D sliding in sockets E E¹. These rods are screw-threaded at their outer ends and

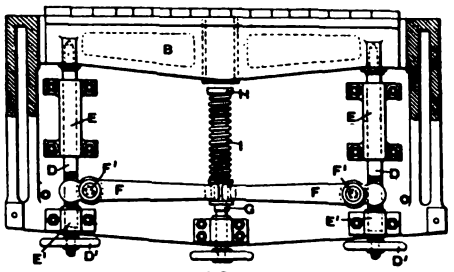

FIG. 1.

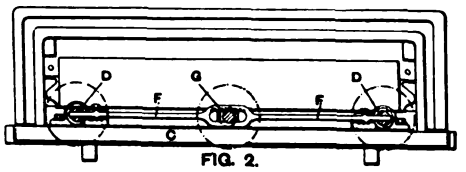

FIG. 2.

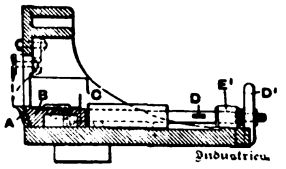

FIG. 3.

receive hand-wheels D¹ for regulating the position of the presser-bar. Two levers F are pivoted at F¹, and the short arms thereof project into slots in the rods D. The longer arms of these levers project between flanges on a sliding collar G on a screw rod H which also carries a helical spring I. By means of the above-described arrangement the presser-bar will "give," so allowing any irregularities in the wood to pass. The presser-bar may be constructed in a number of parts each attached to the slide B by suitable bolts with some elastic material between. Several other structural modifications are described. Seven claims are made.—No. 3086. February 26th, 1890. 8*d*.

Drawing Metal Tubes.—*H. Imray, London.* (*H. Moerchen, Alten, Germany*).—The inventor's object is to reduce the thickness of tubes along the whole length, or to produce varying thicknesses at different parts in the length of the tube. For these purposes the interior of the tube is closed by hammering, pressing, or rolling, or by means of malleable plugs, after having been filled with a pulverulent material of a mobile or plastic nature. The tube so filled, after being heated to a suitable temperature, is passed through grooved rollers so as to be extended longitudinally, while the diameter and thickness are also reduced. If it be desired to produce tubes with greater thicknesses at certain points, the tube, before being filled, has its diameter reduced at the said points. Claims: (1) The process for drawing tubes of reduced thickness by filling the tube with a pulverulent mobile or plastic material, closing the ends of the tube, and then rolling as described; (2) the process of drawing tubes of varying thicknesses by first reducing the external diameter at the parts where the thickness is to be increased, then filling the tube with a pulverulent, mobile, or plastic material, closing the ends of the tube, and rolling as described.—No. 176. January 4th, 1890. 6*d*.

Looms.—*J. & A. Moss, Hebden Bridge, Yorkshire.*—The invention relates to an improved picking motion for looms, in which the shuttle is propelled across the loom by means of a helical spring. The apparatus operated in this manner is shown in the annexed illustrations, of which Fig. 1 is an elevation, Fig. 2 a rear elevation, Fig. 3 a plan, and Fig. 4 details. The crank shaft A, connected by crank arm A¹ to the slay B, carried by the lathe sword C, are arranged as usual. Revolving in brackets on B is a pin D, on which is formed a slotted lever arm E, in the slot in which passes a stud F, fixed to a bracket on the loom frame. On D is also fixed, by means of a suitable crank arm, a hooked arm G, arranged to operate the ratchet wheel H, the spindle of which runs in bearings on the underside of the shuttle-box, and carries a star wheel I (Fig. 4) arranged to operate a spring catch J bolted to the slay, and so release the picker lever K, which is then drawn inwardly, so actuating the shuttle, by means of a spiral spring L, which had been previously compressed, and to which it is attached by means of rods L¹ and sliding flange L². The lever K is forced back to the position shown by means of a lever M, also attached to pin D, which pin is operated by the action of the fixed stud F working in the slotted lever E, each time the slay beats up the weft thread. The star wheel I is also operated by the same

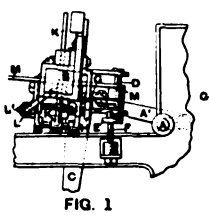

FIG. 1

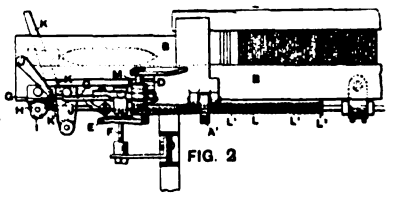

FIG. 2

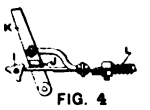

FIG. 4

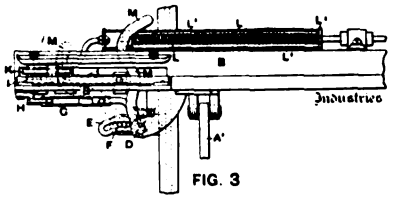

FIG. 3

movement of D, but as the ratchet wheel H has twice the number of teeth as I the latter is only operated once during two beats of the slay. In five claims the inventor embraces the above-described loom-picking motion, together with a modification.—No. 2582. February 18th, 1890. 8*d*.

Steam Boiler Furnaces.—*W. Ackroyd & T. H. Ackroyd, both of Birkenshaw, & J. Willoughby, Gomersall, all of Yorkshire.*—The inventors' object is to cause more complete combustion of the fuel in steam boiler furnaces. For this purpose a pipe of a suitable diameter is carried along the bottom of the flue of the boiler, the front end being bent upwards, and has an L piece of tube hinged to its end; the other end of this L piece is connected to an opening in the door of the furnace. The free end of this pipe is carried part of the way up the chimney of the boiler, and terminates in a trumpet mouth open to the atmosphere. Another smaller tube connected to the upper part of the front end of the boiler is bent downwards and enters the larger tube, and passes through nearly the whole length of same. Just below the trumpet mouth, however, this steam pipe passes out of the larger or air pipe, and is bent round so that its end projects into the trumpet mouth. A strong current of air is thus induced through the larger pipe, which, as it passes through said pipe, becomes highly heated, and ultimately enters the front end of the boiler. Suitable valves are placed in the steam and air pipes to govern the supply through each. Four claims are made.—No. 5453. April 10th, 1890. 11*d*.

Releasing Gear for Boats.—*R. J. Gant, Wiveton, Norfolk, & G. L. Moy, Newclee, Grimsby, Lincoln.*—The invention relates to a method of detaching the supporting chains of ships' boats after the boat has been lowered. Fixed on each end of cross-pieces in the boat are brackets between two vertical arms, of which and at one side thereof is pivoted a pin. At the other side of these arms are formed two corresponding holes, into which a pin can be passed, and which, when the pivoted pin is turned into a horizontal position, holds the said pin in that position, and consequently prevents a ring, which is fixed to the supporting chain or rope of the boat, and which is placed on the hinged pin, from slipping off. The heads of the detention pins are all placed in one direction, and are connected with a central rope, so that by pulling the rope after the boat has been lowered the hinged pins, and consequently the supporting chains, will be released. In a method of releasing the canvas covering the ship's boats the inventors provide said canvas at both ends and at opposite sides with a link of rope or a short chain terminating in a ring. In the stem and stern post of the boat apertures are made sufficiently wide to receive the rings of the front and stern ropes. Pins attached to the aforementioned central rope and passing in holes through the apertures in the stem and stern of the boat overlap the rings therein, so holding them until the central rope is pulled. Claims: (1) In gear for securing and releasing boats and the covers thereof, the employment of a "tumbler" catch,

Digitized by Google

constructed as described, and adapted to secure the boat and its cover; (2) the general arrangement and construction of parts constituting the improved gear substantially as described. —No. 1311. January 25th, 1890. 8*d*.

WIRE STITCHING MACHINES.—*W. R. Bacon, London.*—The machine embraced by this invention is for the purpose of attaching together a number of tickets, labels, or the like, and is shown in the annexed illustrations, of which Fig. 1 is a side part sectional elevation, Fig. 2 a front elevation, and Fig. 3 a plan. Running in suitable bearings in a frame fixed to the table A is a hollow spindle B revolved at a high speed by driving cord passing

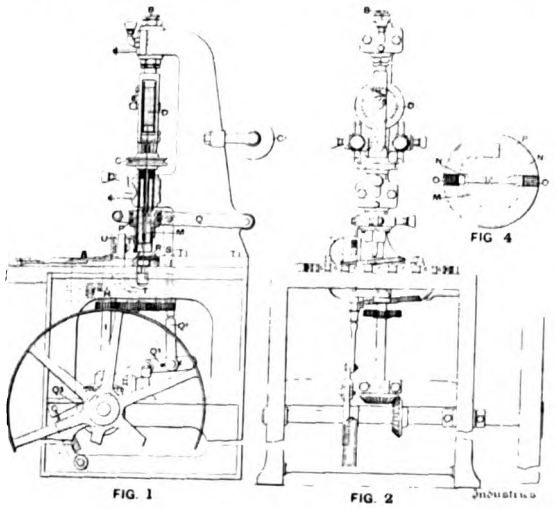

FIG. 1

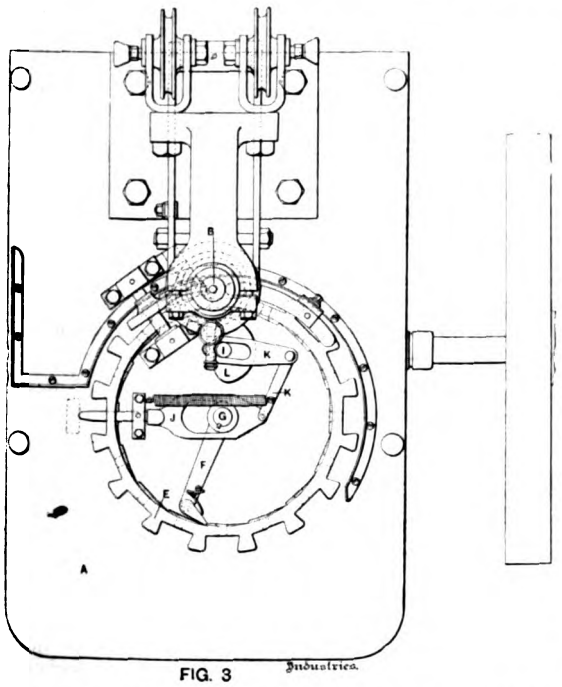
FIG. 2

FIG. 4

around pulley C and guide pulleys C¹. The upper part of B is slotted and carries the wire-containing reel D. A notched ring E is supported on A by means of a flange on its underside running in an annular groove in A, and is driven intermittently by means of a ratchet and pawl F, vertical rocking shaft G, and cam H carried on a vertical shaft I, driven from the main shaft of the machine by bevel gearing. The notches of this ring are made to receive the packages to be stitched, a pusher J being so arranged and operated by means of levers K K¹ and cam L on shaft I as to push the packages out of said slots after the stitching operations. The wire is fed downwards through B from D by means of a sliding block M, furnished with serrated jaws N (Fig. 4) adapted to grip the wire, and engaging with the points of screws O fixed in a sleeve P. This sleeve, and so the sliding block, is given a vertical reciprocating motion by lever Q, rod Q¹, lever Q², and cam Q³. The shearing of the wire is effected by means of a movable blade R, which receives a horizontal reciprocating motion from a cam S operated by spur gearing from I. Two rollers T are arranged in suitable bearings above and below A, the periphery of the lower roller projecting slightly through a slot in A, and the bearings of the upper roller being arranged to slide in guides U and to be pressed downwards by suitable springs. The various parts are so arranged that as the wheel E revolves the wire is first driven through the packages, then sheared off, leaving ends projecting on both sides. The packages are then passed between the rollers T and the projecting end of the wire bent over, the packages afterwards being discharged by pusher J. Claims: (1) In a machine for the above



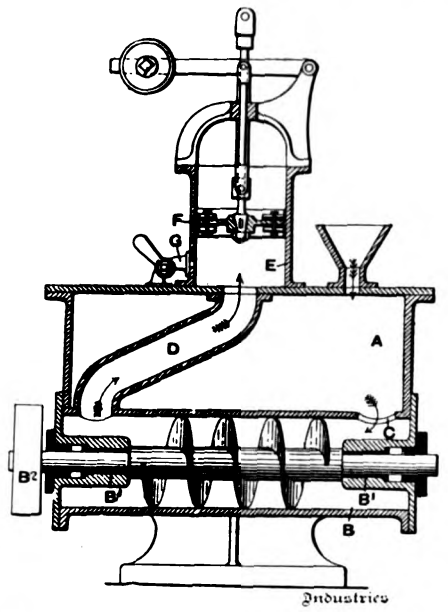


FIG. 3

purpose, the means of driving wire through sheets of paper or cardboard and the provision of mechanism to cause the wire to revolve rapidly so as to prevent its bending: (2) in a machine such as described, the combination of the general arrangement of parts as described, with the provision of mechanism to cause the wire to revolve at a high rate of speed whilst being driven through the tickets, so as to prevent the wire from bending.—No. 2010. February 7th, 1890. 11*d*.

BACK PRESSURE VALVES.—*R. G. Brooke, Salford, Manchester.*—According to this invention, the back pressure valve is, as usual, screwed at the inlet end to receive the pipe conducting the water or other fluid, but this screwed portion is made separate from the body part, but so arranged that, by screwing, it may be suitably attached to the body part. So, when this separate piece, forming the inlet and valve seating combined, is unscrewed from the body portion of the back pressure valve, the latter may be withdrawn together with its seating. The valve is also provided with a projection on its further side to act either as an additional guide or as a stop to limit the rise of the valve. Claims: (1) The arrangement and construction of the screwed portion of the back pressure valve comprising a valve seating, guide, and connection to inlet pipe as described; (2) a stop in the main casing of the valve; (3) the combination with a stop valve of any of the kinds of withdrawable valves and seating as described; (4) the arrangement of a recessed flange to receive the protruding portion of the withdrawable seating as described in a modification.—No. 4856. March 28th, 1890. 8*d*.

SPEED VARYING GEAR.—*W. J. Munden, London.*—The invention relates to apparatus for enabling the speed of a driven shaft to be varied from that of a driving shaft at will, and consists of a worm-wheel, of a pitch varying from one end of the tooth to the other on the driving shaft, and a similar wheel gearing with the first upon the driven shaft, which latter is placed at an angle (preferably of 90 degrees) with the driving shaft and with their axes in different planes. The width of the rims of these wheels is greater than that of the band of actual contact, and consequently by sliding each wheel longitudinally upon or with its shaft a different part of the teeth can be caused to engage, and so the speed of the driven shaft varied. A rod is journalled in a suitable framework embracing the two shafts, and has formed on it radial arms, studs on the ends of which project into annular grooves formed in collars on one end of each of the worm-wheels, so that by suitably revolving said rod the position of the two wheels can be altered as desired. Seven claims are made, embracing the arrangement substantially as described, together with modifications.—No. 3128. February 27th, 1890. 8*d*.

ENGINE GOVERNOR.—*R. Martin, Liverpool.*—A governor constructed according to this invention is shown in sectional elevation in the annexed illustration. Formed in the lower end of

the casing A, which is filled with water or any other suitable fluid, is a circular casing B, in which revolves an archimedean screw journalled at B¹, and driven by means of a pulley B² from the main shaft of the engine to be governed. The interior of B is connected to the interior of A at one end through opening C, and at the other end through a pipe D, with the interior of a cylindrical chamber E, in which works a loaded piston F connected by suitable rods or levers with the throttle valve or other parts regulating the admission of steam or other fluid to the engine. The interior of E is also connected to the interior of A by a pipe G governed by a suitable tap. The action is as follows:—As the water is forced from A into E the piston in the latter is forced upwards, so gradually cutting off the supply of steam to the engine until the supply to E through D is equal to that escaping through G. Should any variation of the speed of the engine occur the piston will be either raised or lowered, and so the engine supply valve either opened wider or gradually closed, as the case may be, until the engine has again attained its normal speed. Claims: The inventor in five claims embraces the governor substantially as described.—No. 4912. March 29th, 1890. 8*d*.

STEAM TRAPS.—*W. A. Clark, Charlton, Kent.*—According to this invention the vessel for receiving the water of condensation is of a rectangular shape, and has connected to one side of it a second chamber, communication being made between the two through a balanced slide valve situated in the first-named vessel and a cooling coil of thin tubing, one end of which is connected to the outlet of the valve, whilst the other end opens into the second chamber. The balanced slide valve consists of a tube, one end of which is connected with the end of the tube coil. The other end, which projects into the first vessel and is closed, has formed in its upper surface a port, over which slides a suitable slide valve, which is connected to one arm of it and is operated by means of a bell-crank lever, the other end of which is fixed to a float. This bell-crank lever is pivoted immediately above the port in the tube in a suitable arm projecting from the side of the first vessel, so that as the float rises the valve opens the port and forms communication between the first and second vessels. A suitable air valve is placed in the cover of the first vessel, which automatically discharges all air when the steam is turned off. Claims: In a steam trap an automatic equilibrium valve having a seat formed of projecting ridges and an adjustable lever actuated by a float; (2) an air valve in the chamber for receiving the water of condensation, with arched metal expansion band and studs; (3) a cooling coil formed of thin metal tubing; (4) a steam trap constructed and arranged substantially as described.—No. 3063. February 26th, 1890. 8*d*.

TUBULAR BOILERS.—*E. Vigers, London.*—The boiler embraced by this invention is constructed as follows:—Each end of the boiler consists of a water casing of rectangular section with arched top. These two casings are connected at their tops by a cylindrical steam space, on each side of which and communicating with it somewhat lower down there is a water tube connecting the two casings, whilst near the bottom there are two other water tubes connecting the end casings. Thus there are four water tubes connecting the two end casings—two at a low level and two at a high level. The upper and lower of each pair are connected by small water tubes, which are bent so as to accommodate increased length in the space and to give narrow passages between them for the products of combustion on their way to the chimney. The whole is enclosed in a casing lined with material which is a bad conductor of heat. Claim: A tubular boiler consisting of two end water casings connected by a central cylindrical steam space and by an upper and lower cylindrical water space on each side of a central fire, the upper and the lower water spaces on each side being connected by small bent water tubes as described.—No. 6668. April 30th, 1890. 6*d*.

NAIL-MAKING MACHINERY.—*H. Campbell, London.*—The inventor's object is to construct a machine for forming and driving brads or nails at one operation. Such a machine is shown in the annexed illustrations, of which Figs. 1 and 2 are elevations of

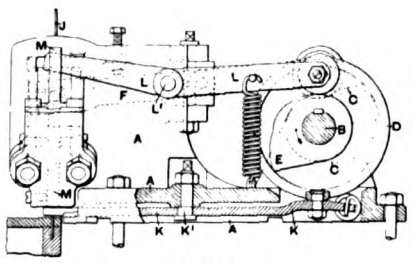

FIG. 1

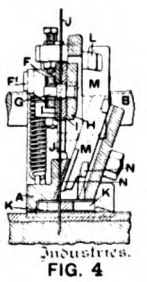

FIG. 4

both sides, Fig. 3 a part sectional plan, and Fig. 4 a part sectional end elevation. Running in a suitable framework A is the main driving shaft B carrying cams C D and E. Pivoted at F¹ is a lever F, one end of which embraces a stud G on a slide H, moving in suitable slide ways in A. This lever is actuated in a vertical plane by cam C so as to carry the slide H up and down, and in a horizontal plane so as to press two collars I placed on the stud G, and between which the wire J, passing through G for forming the brads, passes, by means of cam faces C¹ on C, acting on a flange on the roller on the end of F. Pivoted beneath A at K¹ are two levers K, one pair of ends of which are forced together to grasp the wire J by means of cam D acting on rollers on the other ends. Pivoted at L¹ is another lever L, one end of which is given a vertical reciprocating motion by means of cam E. The other end of this lever is embraced by the slide M carrying the knife N working against a stationary plate N¹. This slide is given first an oblique motion, and then a vertical motion, by means of the ends of stationary set screws projecting into suitable grooves formed in the sides of the slide. The operation is as follows:—The wire is first drawn down by means of gripping collars I; the levers K then hold that part of the wire between them which is to form the brad. Whilst so held the wire is sheared obliquely, and the top part bent over on to the face of one of the levers K by means of the knife N. The part sheared

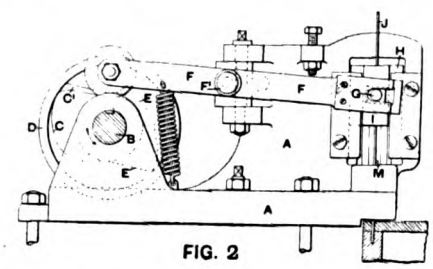

FIG. 2

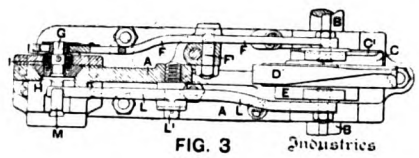

FIG. 3

off is then released and driven into the wood by the latter part of the movement of the knife N. In the meantime the collars I have been released and carried upwards preparatory to a second and similar operation. The inventor also describes a modified machine operated by hand-power. Four claims are made.—No. 3511. March 5th, 1890. 8*d*.

WATER PURIFIERS FOR STEAM BOILERS.—*J. B. Barnes, Springfield, Illinois State, U.S.A.*—The object of the inventor is to free the water from its impurities by heat after it enters the boiler, but before it comes in contact with the flues or any part exposed directly to the fire. The outer shell is formed as usual, and has fixed inside of it by means of segmental rings a second shell, the upper part of which extends only 3in. or 4in. above the crown of the firebox, the edges of the inner shell being bent over towards the interior of the outer shell so as to prevent any solid matter escaping from the annular space between the two shells into the interior of the inner one. An oblong frame made of angle iron is placed on the bottom of the outer shell and supports the inner one. This supporting frame is pierced at intervals along the lower part with semicircular openings, through

Digitized by Google

which the sediment may pass to an opening formed in the lower part of the outer shell, closed by any suitable form of mudhole. Opening into the front part of the annular space between the two shells are the feed-water openings, the water entering through which is caused to flow downwards by means of segmental rings and suitable bars placed across the upper edge of the inner shell and the interior of the outer shell. The segments of the ring do not, however, extend quite to the oblong supporting frame, so that the water, after travelling downwards, passes through an opening between the end of the former and the side of the latter, and escapes into the other part of the annular chamber, and gradually rises and overflows into the interior of the inner chambers. Three claims are made.—No. 20217. December 11th, 1890. 8*d*.

ELECTRICITY.

Telegraph Printing Apparatus.—*H. O. Rudolph, London.*—Fig. 1 in the annexed illustrations is a transverse section, and Fig. 2 a rear view of a transmitter. Figs. 3 and 4 show a plan and front elevation of a receiver, both constructed according to this invention. Referring to Figs. 1 and 2, two rows of levers A A^1,

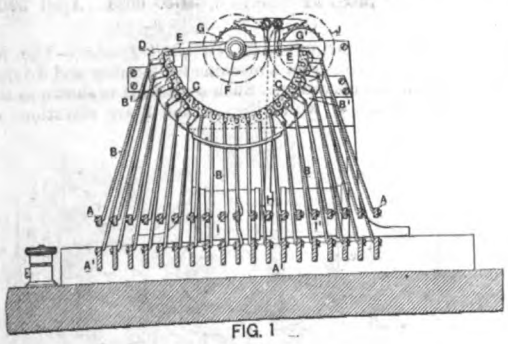

FIG. 1

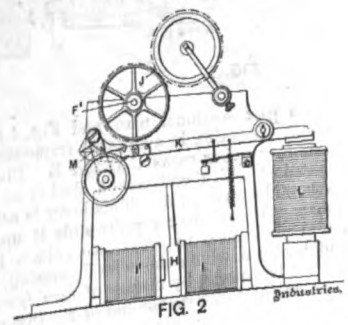

FIG. 2

pivoted as shown, are connected at one end to the keys of a suitable key-board (not shown), and at their other ends to levers B, the upper ends of which are arranged to force pins C out of slots in a segmental frame D, in which they are normally held by suitable springs when operated either directly or by means of bell-crank levers B^1. Revolving above D are two arms E fixed to a spindle F geared to a second spindle F^1, both of which carry ratchet wheels G G^1 operated by means of pawls on the end of lever H, the lower end of which carries an armature and swings between electromagnets I I^1. This armature lever H, as it swings, operates a switch, which opens and closes the circuits around I I^1, so main-

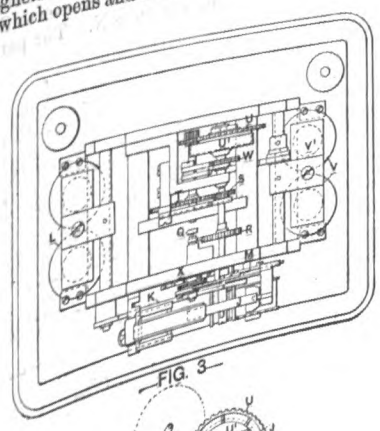

FIG. 3

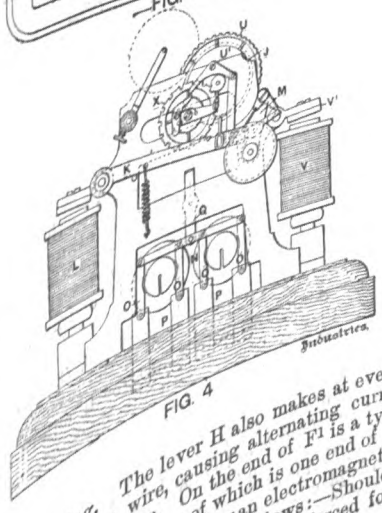

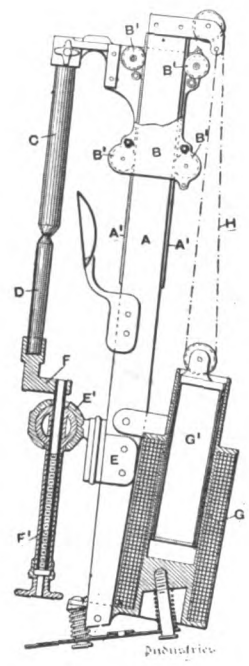

FIG. 4

taining H swinging. The lever H also makes at every stroke a contact with the line wire, causing alternating currents to be sent to the receiver. On the end of F^1 is a type-wheel J the periphery of which is one end of a lever K, which projects over an electromagnet L in series with the line. The action is as follows:—Should one of the pins C will be forced forward and will be struck by one of the arms E, so temporarily checking its motion. This causes a continuous current to be transmitted to the receiver and the magnet L to be excited, so operating K and pressing a strip of paper on the end thereof against the lowest letter on J, which letter corresponds with the key operated. The paper is fed forward on a knife on a lever M operated by the end of K as it is raised and lowered. Referring now to Figs. 3 and 4, the printing mechanism is constructed substantially as that of the transmitter; the movement of the type wheel, however, is effected as follows:—Two electromagnets N, in circuit with the line, have presented to them four iron bars O pivoted to the poles of two permanent magnets P. These bars are alternately attracted, so causing a reciprocating motion of the rod Q, to which they are all attached. A pawl on the upper end of Q governs the rotation of a ratchet wheel R, on the spindle of which is a wheel S gearing with a spindle T, which in its turn is driven from gearing U actuated by a coil spring in the barrel U^1. The action of this arrangement is similar to that of the transmitter. At the same time as the printing mechanism is operated, a second electromagnet V in the line circuit is excited, and its armature V^1, which is on a lever having a pawl engaging with the ratchet wheel W on the spindle of the spring in U^1; thus at each operation the spring is partially rewound. The receiver is also synchronised with the transmitter by means of the star wheel X governed by suitable mechanism operated from the lever Y carrying the printing pad. Five claims are made.—No. 2219. February 11th, 1890. 11*d*.

Arc Lamps.—*C. A. Parsons, Newcastle-on-Tyne.*—Referring to the accompanying illustration, which is a side elevation partly in section of an electric arc lamp suitable for use in search light projectors constructed in accordance with this invention, the steel bar A has formed upon it feathers A^1, and the carriage B moves freely on the bar by means of the four grooved wheels B^1. The carriage B carries the upper carbon C, while the lower carbon D is attached to the lower part of the bar by a bracket E, a ball and socket joint E^1, and a holder F. This holder has a screw F^1, which allows of vertical adjustment, and the ball and socket

joint, together with the cranking of the holder F, permits of ready lateral adjustment. The solenoid G is also attached to the bar A, and its core G^1 acts upon the movable carriage B by the cord H, which passes over suitable pulleys, and is attached to the carriage and the frame of said pulley. The slide is so arranged that it moves in a line at an angle of about 10 degrees to 15 degrees to the vertical plane. The arc is maintained in the lamp in the usual manner by the action of the solenoid G and the core G^1. Claims: (1) In an arc lamp which requires to be moved angularly or moved to varying degrees of inclination, securing a constant or nearly constant difference of weight pull between the carriage and solenoid by the arrangement of carbon carriage, so that its line of movement and the line of movement of the solenoid core are inclined from the vertical plane, and the angle of the solenoid core is greater than the angle of the line of carriage travel as described; (2) the arrangement of upper carbon carriage and holder travelling on a feather or key by grooved pulleys to secure free movement; (3) the arrangement of bottom carbon holder with adjusting screw and ball and socket joint as described; (4) the arc lamp as described.—No. 2659. February 19th, 1890. 8*d*.

Insulating Shaft Couplings.—*C. J. Barley & H. Stevenson, London.*—The invention relates more particularly to the coupling of the armature shaft of a dynamo or other electrical machine to the shaft of a steam engine. The insulated connection is made as follows:—Between the two parts to be connected a disc of insulating material is placed. Through the parts to be connected and through the insulating material taper holes are made, and in these holes are placed taper bolts or screws having fitted over them taper sleeves of insulating material, and which bolts draw and hold the said parts to be connected firmly together. The invention can be applied to the attachment and insulation of parts in electrical apparatus generally. Claims: (1) The means for coupling two parts together and at the same time insulating them from each other as described; (2) the connection and insulation of a spindle to and from a plate by a taper part of the spindle covered with a sleeve of insulating material entering a taper hole in the plate, and a nut with an insulating washer; (3) the use of taper bolts having taper insulating sleeves as described.—No. 4086. March 15th, 1890. 6*d*.

Electric Tension Regulator.—*J. Kalb, Leipsic, Germany.*—The apparatus for the above purpose embraced by this invention is constructed as follows:—Arranged to run vertically on an upright piece of board are a number of resistance coils of German silver, which are connected together in a closed series by contact plates connecting the several coils at the opposite ends thereof so as to form the continuous series, the series being finally connected at each end to terminal screws. The said coils are connected to wires, which project downwards in pairs to varying distances, and are connected by two series of wires with the coils between the same, one wire of each pair leading from, say, the upper connecting plate or the like of the coils, and the other wire of each pair leading to the opposite connecting plate, so that more or less of the coils can be switched in or out to increase or diminish the resistance in accordance with the current. The downward projecting ends are arranged to dip into a mercury bath carried on the end of a suitable iron rod forming the core of a solenoid in the main circuit. The said rod and mercury pot are balanced by suitable weighted levers, and the end of the former is connected to the rod of a suitable "dash pot." Three claims are made, embracing the construction of an electric tension regulator, substantially as described.—No. 5678. April 15th, 1890. 8*d*.

CHEMISTRY.

Treatment of Sewage.—*W. E. Adeney & W. K. Parry, both of Dublin.*—The process embraced by this invention is as follows:—The sewage is first run into a tank of suitable dimensions, wherein the heavier matters in suspension may be deposited. The effluent from this tank flows into a second tank, wherein the liquor is mixed with one or more inorganic oxygen compounds such as potassium, or sodium nitrite, manganate, permanganate, calcium nitrate, manganate or permanganate, or perchlorate, or sulphate, or peroxide, &c., in quantity varying according to the nature of the liquid to be purified. The effluent from this mixing tank is conducted into a third tank of comparatively large dimensions, and there raised to and maintained at a temperature of 75° to 95° Fahr. Under these conditions the micro-organisms in the effluent develop and multiply with rapidity. As a consequence, the soluble organic matters in the liquid become converted into harmless inorganic substances as carbon dioxide and ammonia, and the liquor becomes so much purified that it will not suffer from after-putrefaction. Claims: (1) The purification of sewage and other waste liquors containing organic matters by adding to them an inorganic oxygen compound and maintaining them at a temperature of 75° to 95° Fahr., as described; (2) the purification of acid or alkaline sewage containing organic matters by rendering them neutral or slightly alkaline, adding inorganic oxygen compound, and heating them, as described.—No. 3312. March 1st, 1890. 6*d*.

Colouring Matters.—*J. Imray, London.* (*La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, Paris, France.*)—This invention relates to the manufacture of certain colouring matters by treating fuchsine, dimethylaniline violets, and methyline blue with a mixture of sulphuric and nitric acids, in the following manner:—40·75 kilos. of crystallised dimethylaniline violet are dissolved in 250 kilos. of sulphuric acid at 66° Bé.; the solution is cooled to 0° C., and to it is added in successive doses a similarly cooled mixture of 10 kilos. of nitric acid at 63 per cent. and 20 to 30 kilos. of sulphuric acid at 66°. The whole is left several hours in repose, and then poured into 4,000 litres of water. The sulphuric acid is neutralised by soda or carbonate of magnesia, and the base of the nitrated colouring matter which precipitates is collected on a filter. To convert it into hydrochlorate, this base is mixed with 110 to 120 kilos. of hydrochloric acid at 35 per cent., and the mixture is evaporated to dryness. For nitrated rosaniline, 33·75 kilos. of fuchsine or 32 kilos. of rosaniline are treated in the same way as the dimethylaniline violet, giving a nitrated colour which dyes garnet, being preferably employed as a paste. For nitrated methylene blue, 31·95 kilos. of methylene blue are employed instead of the crystallised violet; the base of the colouring matter produced is dissolved in hydrochloric acid and has bay salt added to it, whereupon is precipitated the nitrated colouring matter which dyes bluish-green. Claims: (1) The process described for nitrating to a greater or less degree fuchsine and other colouring matters by treating them with mixtures of sulphuric and nitric acids; (2) the nitrated colouring matter produced by the said process, with modifications.—No. 6486. April 28th, 1890. 4*d*.

MISCELLANEOUS.

Process for Refining Raw Tin.—*T. Teague, Pinewood, Devoran, Cornwall.*—The inventor treats the raw tin as follows:—The raw tin is run into a suitable receptacle and maintained at the necessary high temperature to keep it in a molten state; suitable pipes of fireclay or other refractory material are inserted into the molten metals, and these pipes are connected with any suitable blowing apparatus, and a current of air, either heated or cold, passed through the metals. This action in the first place oxidises and burns the arsenic, which volatilises as arsenious acid, and may be collected. The iron, if any be present, is oxidised, and forms a small slag; the nickel and cobalt, if present, being deprived of the arsenic, and most of the sulphur separate from the tin, and remain in the vessel in the form of "speiss" after the molten tin has been run out. The same action may be accomplished by means of the addition of Chili saltpetre to the molten mass. Claim: To refine raw tin and expel the arsenic by means of passing a current of air through the metals when molten, and by this means recover the nickel in form of "speiss" and the tin in a practically pure state quite fit for the market, and to produce the same effect by adding Chili saltpetre to the metals when molten.—No. 4860. March 24th, 1890. 4*d*.

Copies of the British specifications may be obtained on application to H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The publisher must be remitted, together with a sum sufficient to cover the postage which may be reckoned at 1d. for every 10d. Remittances exceeding one shilling must be sent by Postal Order.*

IMPROVED SLOTTING MACHINE.

The rapid-acting slotting machine shown herewith has been designed by the Northern Engineering Company, Limited, Halifax, for slotting such work as small links, stops for looms, and small motion work generally. It can be fitted with removable tool-holders specially arranged to hold two tools and furnished with right and left hand screws; two sides of a piece of work can thus be slotted down simultaneously. When fitted with a dividing chuck, hexagons can be finished in three movements of the dividing chuck. The jaws of the chuck can be arranged to hold set screws up to 1¼in. diameter in the shanks. The construction of the machine is simple, gearing being dispensed with. A large cone pulley combined with a fly-wheel enables the machine to be run at a high speed without noise, and ensures a smooth cut. The longitudinal and transverse slides are both self-acting and can be used separately or together. The table is circular, and is rotated by machine-cut worm-wheel and worm.

THE INSTITUTION OF MECHANICAL ENGINEERS.

(*Concluded from page* 306.)

A paper was read on the 19th ult. by Mr. Edward H. Carbutt, Past-President, and Mr. Henry Davey,

On Recent Trials of Rock Drills.

The trials referred to were carried out in the summer of 1890, in connection with the Exhibition of Mining and Metallurgy held at the Crystal Palace. The drills were all of the percussive type, and may be broadly divided into three classes:—(1) Drills in which the valve is worked by air pressure; (2) drills having the valve worked through mechanical connections by tappets or cams; (3) valveless drills, in which the main piston itself performs the office of valve. The drills which took part in the competition were the following:—McCulloch's "Rio Tinto," Stephen's "Climax," Bickle, Ingersoll-Mayne, Daw, Coles, Hathorn's "Eclipse," Ingersoll hand-power, and Bromfield-Ingersoll hand-power.

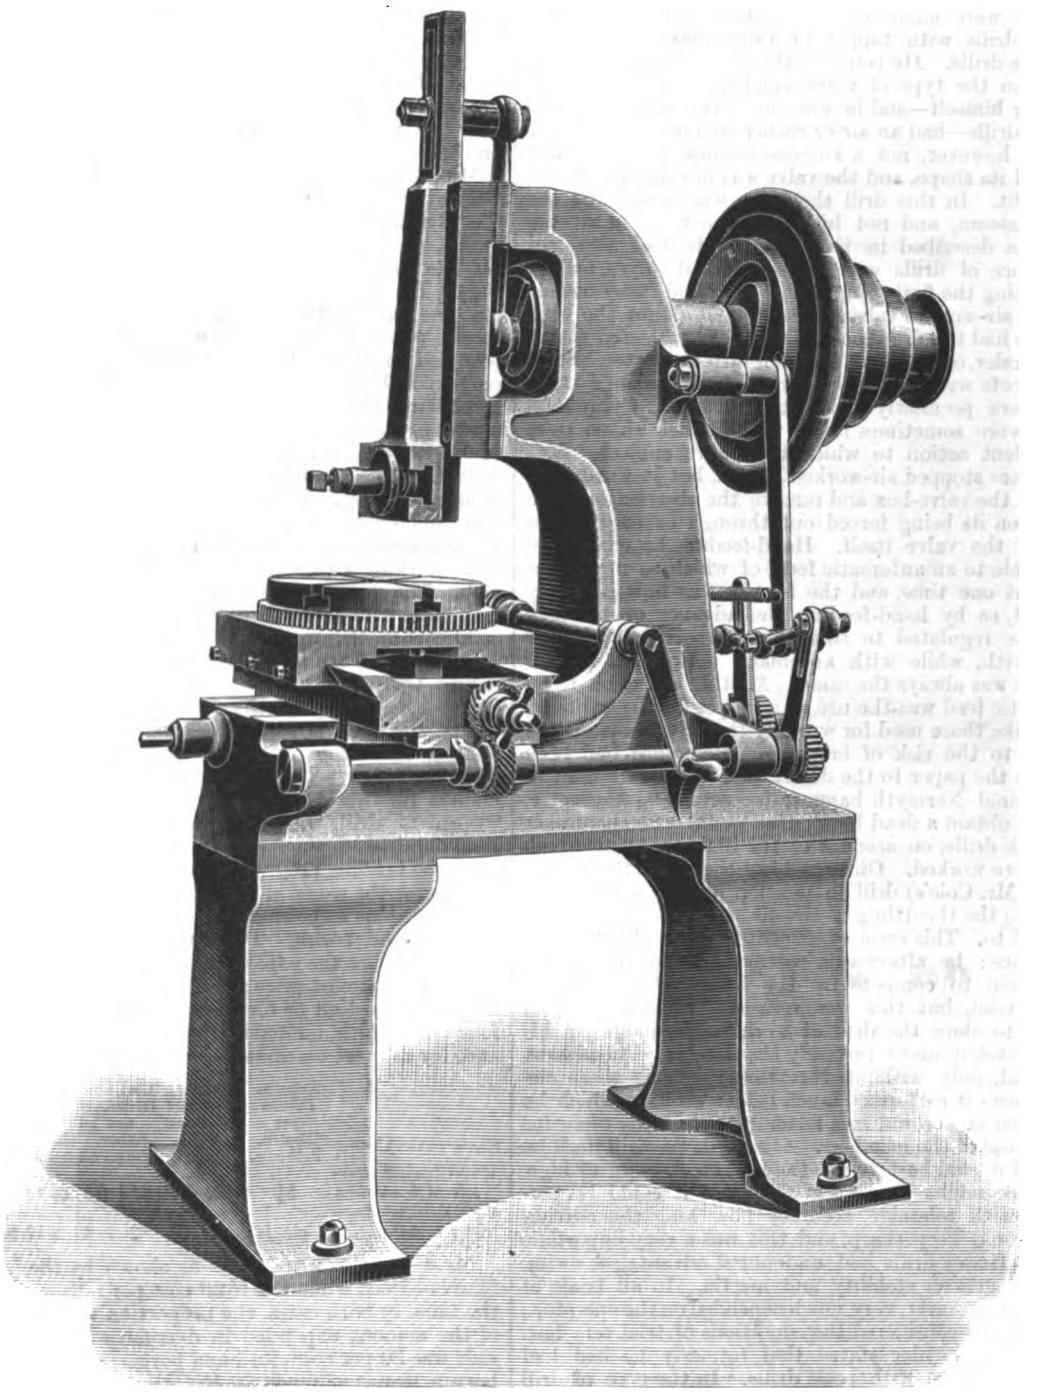
In the paper the construction of each of these machines was described with the assistance of illustrative diagrams, but as we may subsequently publish the paper in full, it is unnecessary to reproduce these descriptions here. The air meter employed for measuring the consumption of air by each drill was one of Messrs. J. Tylor & Sons' inferential water meters. Among the conditions laid down for the competition were the following:—

"Each machine to bore two holes in a granite block, one hole on each side of a centre line which will be marked on the block. Each machine will be required to bore a hole of a diameter equal to half the diameter of its cylinder. After boring, the cubic quantity cut will be measured by pouring water into the hole, or by such other means as the judges may think best. The air used by each machine will be measured by a meter and supplied as nearly as practicable at 60lb. pressure per square inch. Two minutes will be allowed for each drill to bore one hole. Each competitor may use whatever shape of bit he considers best."

The results of the trials were given in a tabular form, and included the depth drilled, volume drilled, air used per minute, granite bored per cubic foot of air. In each case the dimensions and weight of the machine were stated.

On Friday evening, the 20th ult., the discussion on the above-mentioned paper was opened by Mr. Carbutt, who said he regretted that the exhibition of mining machinery at the Crystal Palace had not received more attention, as it was well deserving of study. The trials referred to in the paper were, as far as he knew, the first of their kind, and might be considered as standing in much the same relationship to mining machinery as did the trials of engines at agricultural shows to agricultural machinery. He believed that if such competitions were repeated they would be as beneficial to mining interests as the agricultural contests had been to agricultural interests. All the exhibitors had been very well satisfied. The results of the trials did not enable him to say which was the best drill, since one class of drill was good for one purpose, while another class was equally good for another purpose. He was confident, however, that such trials would do good. As stated in the paper, to form a standard of comparison with the hand-power drills, a hole was bored with mallets and chisels, one man holding the chisel and two striking.

Mr. Le Neve Foster remarked that Mr. Carbutt was mistaken in supposing the trials in question to be the first. As far back as 1866 he had attended a trial of rock drills in Cornwall, and since then various others. He was also present, fifteen or sixteen years ago, in Cornwall, at some comparative tests of ordinary with hand-power and compressed-air drills. Mr. Carbutt had laid stress upon the value of competitions such as those held at the Crystal Palace, but he was not inclined to agree with him that such short trials were of much practical use. The conditions under which a rock drill worked at the surface were so different to those which obtained underground. To form an opinion on the merits of a drill from its behaviour at an exhibition trial was like judging of a man's capacity for endurance in a long-distance contest from his performance in a race of a quarter of a mile. In other respects he was pleased with the paper.



Mr. Collins corroborated Mr. Foster's statement as to trials of drills carried out in Cornwall, which resulted in the early use of such machines in that county. Although he agreed with Mr. Foster's remarks about trials made on the surface, still he thought exhibition trials had some advantages, such as getting together a number of drills of different construction for comparison of their mechanical design. It would be a good plan if competitions could be carried out in an underground level under practical conditions, and he saw no insuperable difficulty in the way of this. The drills should be tested working both upwards and downwards. To work downwards only, as in the Crystal Palace trials, gave an unfair advantage to heavy drills which they did not possess when working upwards. The capacity for wear was an important quality in rock-drills, but in many instances easy replacement of any part would compensate for rapid wear. Economy of power was not always the first consideration with such machines, as in mining districts where water was plentiful power could often be obtained for next to nothing, and then the handiest drill was the best.

The President informed the meeting that the previous speaker, Mr. Collins, had some time ago been honorary secretary to the Institution, and had travelled a considerable distance in order to be present that evening, for which he, the President, and the other members were indebted to him.

Mr. Addy said that he considered the paper a valuable one, but there were some important matters which it did not touch. One of these was the shape of the drill or chisel itself. Among the competing drills he noticed that only one, the "Ingersoll," had a cutting edge of cross form, while all the others were different. He thought it very probable that the breakage of the Ingersoll drill during its trial was due to the form of the cutter. The cross-shaped edge was very suitable for soft stone but did not answer for granite. It was well known that, after its removal from the quarry and exposure to the air, granite became much harder, and possibly this had not been taken into account by the makers of the Ingersoll drill, who had been accustomed

IMPROVED SLOTTING MACHINE.

Constructed by the Northern Engineering Company, Limited, Halifax.

General View.

Digitized by Google

to deal with granite in a comparatively soft condition in the quarry. He should be glad to know whether this had anything to do with the failure. It was a pity the broken drills were not shown to the meeting. Was the quality of the steel in fault or the construction of the drill, or a combination of both?

Mr. Coles, after referring in complimentary terms to the value of the paper, remarked that in it three classifications were mentioned—viz., drills with air-worked valves, drills with tappet or cam-worked valves, and valveless drills. He believed the discussion would turn chiefly on the type of valve employed. The first drill made by himself—and he was one of the earliest makers of rock drills—had an air or rather steam-worked valve. It was, however, not a success, because the valve-box changed its shape, and the valve was in consequence too loose a fit. In this drill the valve was worked by the "live" steam, and not by the exhaust, as in all the machines described in the paper. He had also had experience of drills with tappet-worked valves, among these being the first "Ingersoll" drill, and many others, but the air-worked valves were without doubt the best. Tappets had the drawback that, as they projected within the cylinder, on breaking they fell into the latter. Since the tappets were always constructed of hardened steel, they were peculiarly liable to fracture. Cylindrical valves were sometimes liable to lose their shape from the violent action to which they were subject. Dirt sometimes stopped air-worked valves, but it was better to open the valve-box and remove the obstruction than to rely on its being forced out through excessive pressure by the valve itself. Hand-feeding he considered preferable to an automatic feed, of which so much was heard at one time, and the former was now generally adopted, as by hand-feeding the advance of the drill could be regulated to suit the character of the rock dealt with, while with automatic action the rate of advance was always the same. Another objection to an automatic feed was the use of a tappet in the cylinder, which, like those used for working the valves, was always subject to the risk of breakage. Reference had been made in the paper to the device of a "kicker," used in the original Nasmyth hammer for actuating the valve, so as to obtain a dead blow; this would scarcely answer for rock drills, on account of the high speed at which they were worked. On page 14 of the paper the failure of his (Mr. Cole's) drill to develop its full capabilities, owing to the throttling of the air at the inlet cock, was referred to. This error of construction was due to overconfidence; he afterwards rectified it, and applied for permission to compete on the following day in the tripod trial, but this was refused. Subsequently he offered to show the drill at work to the judges in his own workshop under precisely the same conditions as at the trial, only without throttling. Under these circumstances it performed much better work, of which he had given an account in a letter placed on the table for the perusal of the members. As regards the drill itself he believed it paid best to use the best steel, however high the price might be. From the price it could be predicted with tolerable accuracy how long the cutting edge would keep sharp, and this was a very important point. Heavy drills had undoubted advantages, owing to their greater stability and inertia. In all trials of this kind, however, very much depended on the operator; otherwise he considered the conditions of trial very fair.

Mr. Schönheyder stated that formerly he had had some experience with rock drills. In the type of drill with which he was concerned the valve was very short, so that no trouble was caused by its expansion. The advance was automatic, but was effected without a tappet by means of a separate feed cylinder, the admission port of which was opened at every stroke of the drill. It was noticeable in the later forms of drill, as shown in the diagrams accompanying the paper, that the method of securing the tool to the piston rod was very superior to that formerly adopted, his experience being that after a short time the fastening always worked loose. Mr. Schönheyder objected to the meter used, which he said was all right for a rapid flow, but would not give accurate results with a slow flow. If the meter were used for water with a quantity of 20 cubic feet per minute, equal to 125 gallons per minute, or 7,500 gallons per hour, the record would be fairly accurate, but air was subject to compression, and the conditions in that case were different. The fluid acted on the vanes of the meter by impact, and, therefore, the force exerted would be proportional to the mass. Making allowance for compression to 60lb. per square inch, the relative mass of equal volumes of air and water would be as 1 to 164, hence 7,500 gallons of air would be equivalent to only about 46 gallons of water. In his opinion a much smaller meter ought to have been employed. Some form of gasometer for measuring the air would have been better if practicable.

Mr. Tomlinson explained that Mr. Carbutt and Mr. Henry Davey were in no way responsible for the meter adopted. Mr. Schönheyder was quite right in his criticisms, and, as a matter of fact, the quantity of air consumed had in some cases been omitted from the records because they were convinced of the inaccuracy of the meter. All the conditions of the trials had been arranged beforehand by the Crystal Palace officials without consultation with the judges.

Mr. Bright (of Messrs. Tylor & Sons) explained the circumstances under which the meter was supplied, and stated that no idea of the quantity of air to be passed through was given. He was only informed that the supply pipe was 2in. diameter, and was anxious that the meter should be large enough. Air and water were measured with equal accuracy by such meters, but his firm had no means of testing them with air on their premises.

Mr. Collins gave an account of his experiences in Norway with a rock drill similar in construction to the "Rio Tinto." With this machine he had worked on gneiss, which was much harder than granite. Some of the bits used had a chisel edge, others a cross-shaped edge. The position of the cutting edge relatively to the machine was a matter of considerable importance. From careful personal observation, he had found that the time occupied in actual boring formed an extremely small portion of the total working period. Much time was lost in blasting, changing the bit, setting and adjusting the machine, clearing out the bore holes, &c. The tool had to be replaced after a depth of about 4in. had been drilled. Of the total time about one-seventh was spent in actual boring. In order to test the relative merits of hand and machine work, the same "level" had been driven for five months by hand, and for seven months by rock drills working with a pressure of 60lb. to 70lb. per square inch. The dimensions of the level were 6ft. 6in. by 6ft. 6in. clear. Four men (Swedes and Norwegians) were employed on the work, in two shifts of two men each, working about ten hours per shift; although very skilful miners, these men had no previous experience with rock drills. According to the Norwegian method of hand boring the work is performed single-handed, the miner holding the bit in one hand and striking by a mallet with the other. The bits were of ⅞in. steel and the mallets 4lb. in weight. The rock drill used was a 3⅛in. "Cornish" drill, the tool being made of the best drill steel obtainable.

As the heading progressed, there was perhaps a slight change for the worse in the character of the rock, making the conditions somewhat harder for the rock drill than for the hand boring. Dynamite (No. 1) and gelatine dynamite were the explosives used, which were paid for by the men at cost price; no charge was, however, made for compressed air or for sharpening the borers, and the following figures, quoted by the speaker, include no allowance for interest on capital or depreciation:—

	Average Driven per Month. Fathoms.	Average Cost per Fathom of Level.	Cost for Dynamite and other Materials.	Cost for Labour.	Average Wages earned per Day.
Hand boring, average of 5 months	3¼	£5 6 0	£1 11 10	£3 14 2	2s. 8d.
Rock drill, average of 7 months	4fms. 5ft.	5 5 0	2 7 3	2 17 9	3s. 3d.

Mr. Collins pointed out—as shown by the preceding figures—that, while the total cost per fathom was much the same in both cases, the proportion to the whole cost of the amount expended in dynamite and other materials was 30 per cent. for hand boring, while for machine boring it was as much as 45 per cent., the proportions for labour being respectively 70 and 55 per cent. The following further data, the speaker believed, might be of interest:—

	Lbs. of Dynamite used per Fathom of Level.	Lbs. of Steel used per Fathom of Level.	No. of Holes bored per Fathom of Level.	Average Depth of Hole.	Depth bored by each borer without sharpening.	Depth of Holes bored per Shift (1 machine & 2 men).
						ft. in.
Hand boring	20⅛	4¾				
Rock drill...	32½	7⅞	32⅛	43½in.	4½in.	13 10½

All time lost in blasting, &c., was included in the particulars stated. The chief advantage of machine boring, it was evident, consisted in the increased speed, which, of course, was of very great value. The greater quantity of explosive material used in machine work was very noticeable, being nearly twice as great per cubic yard as for hand boring. The extreme hardness of gneiss was strikingly demonstrated by the fact that, while in hard granite the drill would bore 6in., it would only penetrate 1in. in gneiss during the same time. As a very desirable improvement in the construction of rock drills, Mr. Collins offered the suggestion that the turn at each stroke should be varied according to the nature of the rock, instead of fixed, as at present, in ordinary machines. That an alteration of this character was required was shown by the very different character of the *débris* removed from the holes in soft and hard materials. The cost per fathom given for machine driving did not include the extra skill necessary for sharpening the chisels.

Mr. Reginald Bolton said that his experience ranged over a considerable number of different rock drills, and that he had put the first "Eclipse" machine that arrived in this country to work, and was acquainted with all the leading machines, most of which were not described in this paper at all. He had some criticisms to offer upon the drills shown, and, commencing with the question of the rotating motion. He pointed out that it was substantially the same in all the diagrams. The arrangement shown in the illustration of the "Climax" drill was, however, open to considerable objection, as there were far too many points of friction and impact in the sliding of the pawl over the ratchet wheel teeth. It was essential to have not only a pawl engaging the teeth, but a second pawl half engaged, so that in hard rocks, or with shortened strokes, the pawl would catch with a turn of half a tooth. The present stereotyped form of rotating mechanism was a weak feature in all drills, and the teeth were not unfrequently entirely stripped off a ratchet-wheel by the breakage of a chip off one pawl or tooth. The "Cranston" drill, used in the North-Eastern district, had a band rotation, which was a good feature in certain cases. Referring to the valves shown, the speaker commented on the great similarity of those worked by fluid to the "Eclipse," from which they seemed to have been copied, but he considered the "Coles" valve-box too light to stand a miner's usual method of giving vent to his feelings on a rock drill by a blow with a hammer or chunk of rock. The "Climax" valve was also a very old device. The "Daw" drill was not fully described, nor illustrated in the paper, as he hoped it would be, since he wished to become acquainted with the details of every rock drilling machine. With reference to the breakage of the Ingersoll drill, Mr. Bolton expressed the opinion that the bit failed owing to excessive hardness. Makers of rock drills paid too much attention to the design of new valve gears and unimportant details, and gave too little consideration to the essential point of obtaining the greatest force of blow. The speaker advised the use of higher air pressures than those usually adopted, even up to 120lb. per square inch, by which means a greater percentage of work could be obtained out of a given tool in the same time. He himself had tried pressures of from 90lb. to 100lb. The better results achieved in tunnelling in the United States were in great part due to the use of higher pressures and deeper blast holes. He himself, with a 2½in. "Eclipse" drill, working with 90lb. pressure, had succeeded in perforating 12in. of Leicestershire granite with a hole 1⅝in. diameter in one minute. This went to show how much the work done by a drill might vary according to circumstances, favourable or the reverse. Mr. Bolton then proceeded to criticise very severely the manner in which the trials described in the paper had been conducted. The so-called trials, he said, showed nothing and proved nothing, while the results obtained had no value. Even trials under working conditions were not always reliable, as often more depended on the man than on the machine, and he knew of at least one case of a competitive test in which a machine, after being condemned for failure on one day, achieved on the following day a most remarkably superior result, brought about by the judicious expenditure of some of Her Majesty's standard coinage! As a matter of fact, which he knew from his own experience, all such trials were very unreliable, and established nothing except the ability of the man who worked the machine. Reference had been made to the steam trials at the Royal Agricultural Society's shows; but he could tell the meeting that the engines taking part in the competition were often ordinary agricultural engines only in outside appearance, and in their internal details sometimes differed considerably from these. The leading portable engine makers now avoided such contests. A water meter should not have been employed to measure the air. The proper way to do this was by pumping a large reservoir full to a fixed pressure, and from this supplying the drill until the pressure fell to another fixed point. The conditions laid down as to the diameter of the holes bored were absurd. A hole of 1¼in. diameter bore quite a different relation to a 2½in. drill piston and bit to that which a 1¾in. hole bore to a 3½in. drill and bit. The case was very much as though in a steam engine competition the trials were conducted under the following conditions:—All the machines fastened to a loose foundation, the diameters and strokes being different. The number of revolutions unknown. The steam supply measured by, say, a gas-meter. Flywheels all alike, connected by bands to saw-benches. The diameter of saw to be double the diameter of cylinder. All the saws to cut for two minutes in the same block of wood. The cuts to be measured with scientific accuracy, and the result stated as follows—"Wood removed per cubic foot of steam registered in the gas meter." Would any engineer purchase a machine on the strength of the results of such a trial?

Mr. Lockart expressed himself as being much interested in the Norwegian method of hand-working by one man, described by a previous speaker. The question was—

Digitized by Google

Could three men working singly in this manner do more than when acting in combination, with one man holding the drill and two striking? His own experience of piecework was that more could be accomplished when the men worked singly than when they were combined. A larger number of holes were bored in less time.

Mr. T. Wilson (representing Mr. McCulloch, the maker of the "Rio Tinto" drill) remarked that Mr. McCulloch's drill could not rightly be classified under either of the heads mentioned in the paper, inasmuch as it was a combination of both tappet and air-worked valve. In some cases the valves of rock drills were actuated by tappets only, and in most of these cases it had been found necessary to employ a spring to keep the valve in its place at the end of its stroke, when the tappet was not in contact with the swelling or enlargement on the piston or rod. Under these circumstances it was generally found either that the spring was too strong, and caused excessive friction, or that it became reduced in strength by wear to such an extent as to be useless for its purpose. In other cases, notably those of the "Climax" and "Ingersoll" drills, the valve was kept in its position by the pressure of the air or other motive fluid acting on the back of it, but this, like the spring, caused excessive wear, not only on the face, but on all the moving parts. The valves of some rock drills were actuated entirely by the working fluid, but in practice this was found to be unreliable, as the valve, when it became worn, was apt to flutter or stick, owing to the leakage of air past it, or was rendered entirely inoperative by the entrance of sand or grit—for instance, rust off the interior of the pipes. In tappet valves such obstructions would be forced away by the blow of the piston. In the "Rio Tinto" drill, as soon as the valve had been moved to the end of its stroke by the tappet, the air pressure acting upon the opposite end prevented any movement while the enlargement on the piston rod was out of contact with the tappet, thus avoiding the friction caused by springs or pressure on the back of the valve.

On the conclusion of the discussion the secretary, at the request of the President, read two letters from members unable to be present at the meeting. The first of these was from Mr. Stevens (who is connected with the "Ingersoll" hand-power drill), in which he characterised the trials as useless. The second letter was written by Mr. David Joy, and referred to some early records in the possession of the writer, of trials of rock drills in the Cleveland district. Mr. Joy stated that the chief difficulty in the way of their introduction at that time arose from the opposition of the workmen.

Mr. Carbutt, in replying to the discussion, stated that he and his colleague were in no way responsible for the conditions under which the trials were carried out, as these had been settled without any reference to their opinion. If any of the competitors were dissatisfied they had only themselves to blame, as all the arrangements were made after consultation with them, and with their full consent. In spite of Mr. Reginald Bolton's strictures, Mr. Carbutt was, he said, convinced that the trials of the Royal Agricultural Society had been beneficial to agricultural engineering.

THE "CLYDE" PISTON RING.

We illustrate herewith a form of piston ring which has been invented by Mr. James Menzies, 52, Mount Street, Glasgow, and which is claimed to be extremely simple, safe, and efficient. We understand that it has been applied in a number of marine engines, under exceptionally severe conditions, and with the best results.

The construction of the ring will be understood from the illustrations, Fig. 1 of which represents a horizontal section, Fig. 2 a plan of the spring and rings, Figs. 3 and 4 represent a modification, and Fig. 5 shows a general view of the complete ring, for which the following advantages are claimed:—When the junk ring is screwed down, the rings and springs are bound together, leaving the packing practically in one piece. By fitting the body of the piston to the parts formed on the inner surface of the rings, the packing is supported under shocks, and the piston under oscillations. The vertical pressure remains constant, the springs and pressing heads not being subject to wear in the slightest degree, while the adjustments are independent and allow either the vertical or lateral pressure to be increased or diminished as desired. The arrangement is said to have all the elasticity and rigidity required to keep the cylinder in good order when the engine is new or the cylinder in fair condition, and when cut in sections and fitted to an unequally worn cylinder results are obtained which give general satisfaction. All the springs in the ring are interchangeable except the one fitted at the saw-cut section. The modification shown in Figs. 3 and 4 is particularly applicable to pistons for new cylinders.

THE AGRICULTURAL PROSPECTS OF CANADA.

On the occasion of the visit of the Iron and Steel Institute to America last year some of the members gave glowing accounts of the industrial resources of Canada, and prophesied a great future for it as a manufacturing centre. These opinions were, no doubt, correct to a very large extent, but the Canadian Government has very wisely determined that due attention shall also be paid to the oldest industry—that of agriculture. In August of last year we directed the attention of our readers to the fact that the High Commissioner of Canada, by the instructions of the Minister of Agriculture, had invited representative tenant farmers from different parts of the United Kingdom to proceed to Canada to report upon its agricultural resources, and the advantages the country offers for the settlement of farmers and farm labourers, and of other classes for which there is a demand. The reports of these gentlemen have now been published, and we commend them to the attention of all who may have any idea of settling in Canada or of sending their sons to that country. They have been issued in four parts, the first two of which are by the delegates from England, while the other two are by those from Scotland and Ireland. This plan makes them more convenient for distribution, which is being done very freely by the agents of the Canadian Government throughout the country, and also by the various steamship agents who are to be found in almost every village. The different representatives have, of course, looked at the subject from their own point of view, or rather from the point of view of the suitability of Canada as a place of settlement for people from their own parts of the United Kingdom, and, of course, there is thus a considerable variety of opinion. The Canadian Government has also issued a new edition of its official handbook, and in it will be found a large amount of trustworthy information which should be carefully studied by intending emigrants.

In the preface to the reports of the delegates will be found a synopsis of the land regulations in the different provinces of the Dominion, relating to free grants of land. It also gives the prices of farms which have become vacant from various reasons, and are most suitable for persons possessed of some means, who desire more of the social surroundings than can be obtained in those parts of the various provinces in which Government lands are still available for occupation and settlement.

The importance of Canada, from an agricultural point of view, may be estimated from the fact that the value of its agricultural products alone now reaches nearly $40,000,000 per annum, in addition to the immense quantity required for home consumption. The climate of Canada seems to largely deter many people from thinking of Canada as a place of residence. No doubt the winters in many localities are severe, but, on the whole, it is one of the healthiest of countries, as is shown, not only by the statistical returns, but also by the general healthfulness and physique of the population, which is a subject of remark by all visitors and new settlers. Canada has now a reputation for fruit far beyond its boundaries.

We cannot, of course, enter into details of the various reports, but we may say that they all contain a very large amount of information. The delegates do not hesitate to give candid opinions where these are necessary, on the different points brought under their observation, and have not endeavoured simply to "write up" the country. They give particulars of the climate, soil, methods of agriculture, land regulations, experimental farms, roads, dairy farming, cattle ranching, wages, loans, schools, churches, and taxes, and they do not hesitate to point out some of the defects of the country. In some districts drought causes considerable difficulty, while hail storms, autumn frosts, and occasionally locusts and mosquitoes, give trouble. As to the class of persons principally wanted in Canada, Mr. John Speir, one of the Scotch delegates, points out that they are farmers of all classes, farm servants, domestic servants, and a few artisans; all others are, for the present, unlikely to be any more successful there than at home. The men likely to meet with most success are those who have been in occupation of the smaller class of farms at home, and who, between themselves and their families, can do a good proportion of their own work, for labour is so costly that if much of it has to be hired a considerable part of the profit is thus lost. We cordially commend the whole of the reports to the attention of those of our readers who are interested in Canada.

OIL-FIRED BOILERS FOR SUBMARINE VESSELS.

It is a recognised fact that, if petroleum is to displace the use of coal to any material extent as fuel for generating steam, it must, to compare favourably, be employed in boilers specially designed for its combustion. Messrs. Fraissinet & Co., of Marseilles, whose exhibits of marine boilers at the late Paris Exhibition attracted a considerable amount of attention, seem to have made a special study of the adaptability of oil fuel for boilers employed in submarine navigation. That this study has met with considerable success will be seen from the particulars and illustrations, given herewith, of two boilers of the above class, one of which is designed for

working under ordinary draught, while the other is capable of working either under ordinary conditions or under air pressure. In Figs. 1, 2, and 3 we give a longitudinal section, a front elevation, and a transverse section of a boiler of the first-named type.

This boiler has been constructed for a working pressure of 130lb. per square inch. It is 13ft. 9in. in length over all, 12ft. 1in. from the back to the front plate, the length of the tubes being 10ft. The external diameter is 6ft. 6in., and the internal diameter of the furnace about 2ft. 4in. As will be seen, the boiler is of cylindrical form, with an internal furnace, slightly projecting beyond the front of the boiler, lined with fire-bricks for about two-thirds of its length, terminating in a combustion chamber, and, except for its relatively long furnace and the omission of fire-bars, similar to an ordinary return multitubular marine boiler. The extension of the furnace A at the front of the boiler is formed of wrought iron, with a cast-iron front B. The air required for combustion is supplied direct to the furnace by means of a ventilator connected to the pipe C, the air being divided into two currents as it enters the box A, through the orifices D, an air pressure equal to 1in. of a column of water giving good results. It will thus be noticed that instead of the air for combustion passing into the furnace in the same direction as the oil fuel, it enters at right angles to the latter, and this arrangement, it is claimed by the makers, ensures a more complete mixing of the gases and more effective combustion. On the front of the furnace two jets or burners E E for supplying the liquid fuel are placed (see Figs. 1 and 2). The petroleum, being first pumped into storage tanks or bunkers, flows through the piping F into the reservoir G, which is supplied with a glass gauge, so that the engineer can be certain of having an ample supply in the reservoir, from which it passes through the pipe H into the burners E E (Fig. 2), the steam or compressed air necessary for the splitting up of the petroleum being supplied through the pipe I. In Figs. 4 and 5 enlarged views of one of the burners are given. Through an inlet the petroleum passes into the conical receptacle K, which is formed of gun-metal, its escape into the furnace being impeded and regulated by the spindle L, which is manipulated by means of the hand-wheel M being advanced or drawn back on the screw N, the maximum annular opening for the escape of the petroleum being two millimetres. The steam or compressed air supplied through O surrounds the oil space K, and when steam is employed increases the temperature of the petroleum and passes between the cones K and P in a cylindrical spray, enveloping the petroleum and projecting it in the form of spray into the furnace. In this respect this oil injector is similar to others employed by other firms, but this, the J. d'Allest petroleum injector or burner, has also provision for increasing the quantity and the effectiveness of the consumption of oil, this being found necessary where, as in torpedo boats, a maximum power is required. For this purpose the spindle L is made hollow, so that the steam or compressed air can enter into it at S and pass through the centre of the spindle L. By this means the petroleum passes into the furnace surrounded with two currents of steam or compressed air, so that no particle of oil escapes the splitting up action, the operation being similar to an Argand burner. The operation of lighting the furnace is similar to other petroleum furnaces, by means of a torch, and when a sufficient quantity of air is obtained through the ventilator there is complete combustion and an absence of smoke. As already indicated, in the boiler illustrated there are two fuel injectors or burners, and this arrangement considerably facilitates operations and practically obviates the possibility of stoppage in the supply of fuel to the furnace, as well as giving greater control over the generation of steam. Each injector being provided with a stop-cock to the oil supply, either of them can be extinguished and again relighted. If, by any means, the injectors should become choked, the rapid turning of the

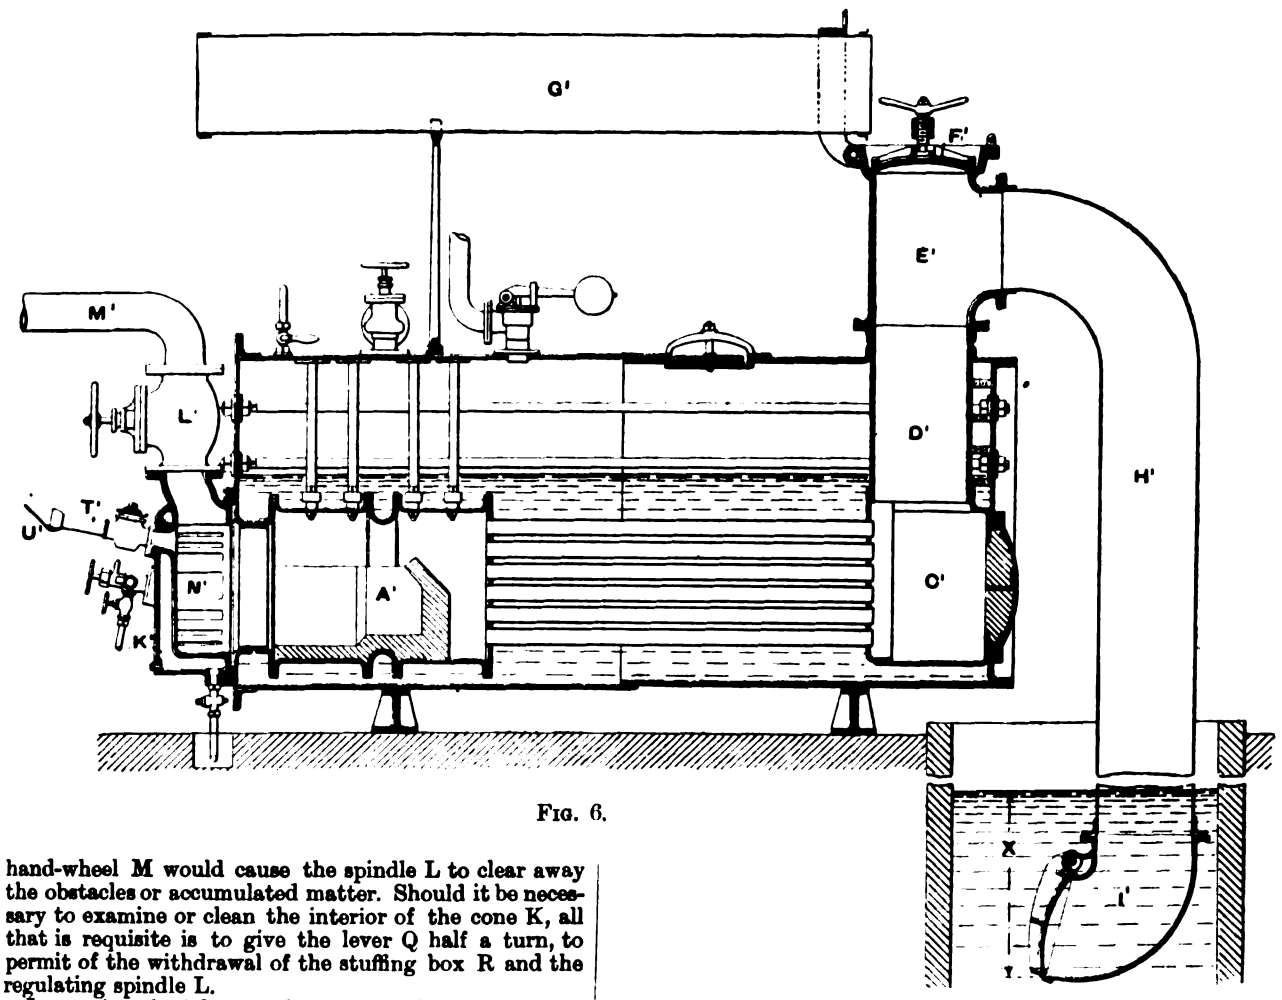

FIG. 6.

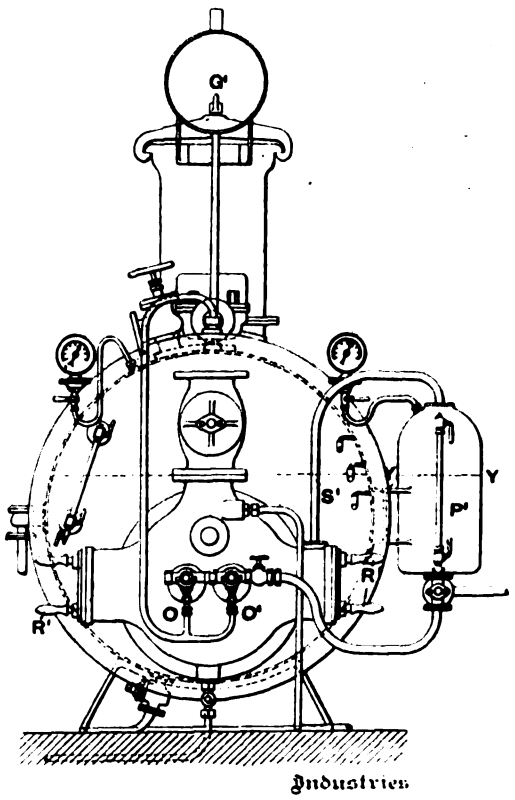

FIG. 7.

hand-wheel M would cause the spindle L to clear away the obstacles or accumulated matter. Should it be necessary to examine or clean the interior of the cone K, all that is requisite is to give the lever Q half a turn, to permit of the withdrawal of the stuffing box R and the regulating spindle L.

In a series of trials carried out with this boiler on land, there has been no difficulty in evaporating 80 litres of water per square metre of heating surface per hour—equivalent to 16·35lb. of water per square foot of heating surface. At this rate of evaporation, a tendency to priming was experienced, but with about 70 litres evaporated per square metre of heating surface the water was ordinarily tranquil. Adopting 70 litres per square metre of heating surface as the normal evaporative capability, this boiler, having 100 square metres of heating surface, will evaporate 7,000 litres of water per hour, and the total weight of the boiler, including water, fire-box, air conduits, and all usual fittings, being 13,108 kilogs., the weight of boiler, water, &c., per kilogramme of steam is 1,872 kilogs., with a fuel consumption of 636 kilogs. of petroleum per hour. The quantity of water evaporated per kilog. of petroleum, under these conditions, is 11·06 litres, or 11lb. of water evaporated per 1lb. of petroleum.

There are, no doubt, important advantages to be derived from the use of liquid fuel in torpedo boats. With boilers of the type above described, using liquid fuel, the closed stokehole is dispensed with. From a naval point of view, the absence of smoke, sparks, &c., when petroleum is used as fuel, is also important, as the destination and whereabouts of the vessel would not be so easily gauged by the enemy. Reference has already been made to the saving of weight in the boiler, &c., owing to the greater evaporative efficiency of petroleum, but such an important feature can scarcely be over-emphasised, as it renders possible greatly increased speed with equal weight of boilers, or decreased weight and equal speed. In the boilers constructed on J. d'Allest's system it is also noteworthy that the evils common to boilers of the locomotive type fitted in torpedo vessels—due to the excessive local heat—are obviated by the adoption of a fire-box and return tubes, 196 tubes of 2in. external diameter being fitted in the boiler illustrated in Figs. 1, 2, and 3.

The above illustrations (see Figs. 6, 7, and 8) represent a marine boiler for burning liquid fuel, specially designed by the same firm for submarine vessels. Fig. 6 shows a longitudinal section, Fig. 7 a front elevation, and Fig. 8 is a transverse section of the boiler, which is 9ft. 3in. in length from back to front plate, and 4ft. in external diameter, with one furnace A^1, having an internal lining of fire-brick on the bottom and sides and a bridge of the same material. The furnace is connected to the combustion chamber C^1 by 58 tubes, 2¼in. external diameter, 4ft. 10in. long, the whole boiler being constructed for a pressure of five atmospheres. On the smoke-box D^1 is placed a casting E^1, which can be closed as shown at its upper part by a water-tight manhole door F^1 when the vessel is to be submerged, the ordinary funnel G^1 being hinged so as to be canted over and rest upon a suitable support. Connected to the casting E^1 is another funnel H^1 leading into the water either under the

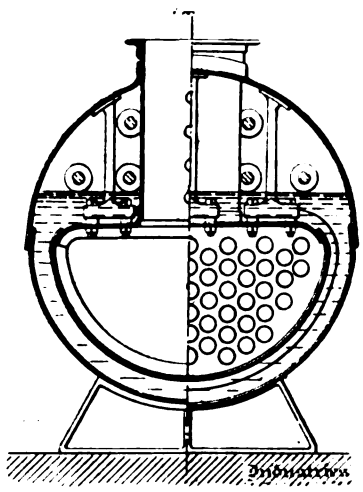

FIG. 8.

bottom, or through the sides of the vessel, having at its extremity a sea valve I^1. The front of the furnace K^1 is of cast iron and fitted perfectly air-tight. air under pressure being supplied to the furnace through the pipe M^1, a stop valve L^1 being placed intermediately to regulate its supply. The air meets the liquid fuel at right angles, as in the previously described return tube boiler, passing through the apertures N^1, the petroleum from the reservoir P^1 being injected through two burners or pulverisers O^1 O^1, shown in Fig. 7, and also upon a larger scale in Figs. 4 and 5, attached to the front of the furnace. It will be apparent that this boiler can be either worked under ordinary draught or under pressure. In the former instance, the manhole door F^1 is removed, the funnel G^1 raised to an upright position, the plugs R^1 (Fig. 7) unscrewed, and then, if the pulverisers are set to work and the furnace lighted, the boiler works in the usual manner, the air necessary for combustion entering through the openings R^1, and the products of combustion escaping by the funnel G^1. Supposing, however, a vessel in which this boiler was fitted was being submerged, the manhole F^1 and openings R^1 would be hermetically closed, compressed air being forced into the furnace through the pipe M^1 (Fig. 6) at a somewhat greater pressure than that represented by a column of water X (Fig. 6), viz., the depth to which the valve I^1 was immersed. Combustion would thus continue to be effected, the unconsumed gases being forced to the valve I^1, by which they would escape, provided the supply of petroleum to the furnace was continuous. This is provided for by connecting the reservoir P^1 with the furnace by a pipe S^1 (see Fig. 7), so that the same air-pressure will exist, in both the furnace at the front of the pulverisers and the portion of the reservoir P^1 above the level Y Y of the petroleum, the weight of the latter causing it to flow to the pulverisers or injectors whatever the pressure of air supplied to the furnace. The difficulty of ascertaining the rate of combustion, in the hermetically closed furnace, has been overcome by providing a tube T^1 (Fig. 6) closed at its external end by a thick glass; as, however, the latter might suddenly break, a small hinged mirror U is provided, so that the observer may see the condition of the fire by reflection and escape the danger of being burnt. For submarine purposes a sufficient quantity of compressed air would have to be stored in the vessel, with reducing valves, so that the air used in the furnace of the boiler might be at a suitable pressure, this being dependent, as already indicated, upon the depth of immersion, readily ascertainable by a hydrostatic pressure gauge. As to how far submarine navigation is practicable with liquid fuel, as compared with stored steam, or electric motors driven from accumulators, is no doubt a question of moment. In any case there are serious drawbacks, but Messrs. Fraissinet & Co. at least deserve credit for their enterprise.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 31st March, 1891.

Iron.—A meeting was recently held at Paris of several of the largest forge-owners in the country, at which it was unanimously agreed to limit the production of iron, and, if necessary, to reduce the number of working days, and also to immediately raise the market price of the metal 8s. per ton. In the face of this co-operation on the part of the producers, nearly all the merchants on the Paris market have issued circulars quoting bars at 136s. 7d., and joists at 144s. 7d. per ton. These prices will be approximately adhered to, except in the case of very important orders, when an allowance of 3 or 4 per cent. may be made. Old iron rails continue to be quoted at 72s. 4d., and there is a good demand for castings at 112s. 6d. per ton. From the provinces the reports are, in general, good, and testify to a steady improvement in the iron trade throughout France. Several important orders have been received in the North from abroad. A strike of puddlers has taken place at Hautmont, where there are altogether 2,000 men idle, and some fear was expressed of the disaffection spreading further. The cause of the men leaving their work in the first instance was a reduction of 5 per cent. in their wages.

Coal.—There is no change in the state of the coal market. The demand is especially strong for the classes of fuel used for manufacturing purposes.

Copper, Tin, Lead, and Zinc.—The copper market remains stationary. Best Chilian bars are quoted at £56 8s., and ordinary Chilian bars at £54 10s. per ton. Tin has fallen 10s. per ton, and the demand for this metal is generally weak. An order for 22 tons of tin has been given by the French Admiralty at £92 16s. 8d. per ton. Lead continues to be quoted at £13 2s. per ton. The zinc market is weaker than it was, all qualities having decreased in value 7s. per ton.

Atlantic-Mediterranean Ship Railway. — Some time ago a proposal was made to construct a ship canal through France to convey vessels from the Atlantic to the Mediterranean without their having to go round by way of Gibraltar. This proposal was, however, given up on account of the great cost. It is now reported by your contemporary, *Annales Industrielles*, that a special committee has been formed at Bordeaux which proposes to replace the ship canal by a ship railway of a length of about 280 miles.

Cable Tramways in Paris.—It has been proposed to facilitate the communication of some of the high-lying parts of Paris with the more central districts by means of the establishment of rope tramways, and with this object a line was constructed last year joining the Belleville quarter with the Place de la République. A preliminary trial of the line was not satisfactory, and its opening was deferred until the necessary modifications had been made. Another series of experiments was afterwards undertaken, when it was found that either the traffic or the frost, or, perhaps, both, had caused the opening of 20 millimetres, which serves as a passage for the grip, to be contracted in places to 11 millimetres. This opening had been left as narrow as possible to obviate the danger of carriage wheels getting into it, but it has now been enlarged throughout to a uniform width of 28 millimetres. The endless rope was then found to have become slack, and it was only recently that the trials could be recommenced. On this occasion the cars worked fairly well, and on their first trips attained the speed of 120 metres per minute, or two-thirds of their proposed normal velocity.

VIENNA, 30th March, 1891.

The Iron Market.—There has been no change in the Austrian iron market during the past week. The market generally is dull, and only materials used for constructive purposes maintain their price. At a recent meeting of the Pilsen Machine and Waggon Works Company, a report was presented to the shareholders, which showed a profit of 13,000fl., and it was resolved that a dividend of 6 per cent. should be paid.—The shares of the Alpine-Montan Company are being much inquired for. It is reported in the money market that this company has made a profit of three million florins during the past year, and will pay a dividend of 6½ per cent. During the previous year the company made a profit of 2·2 million florins, and paid a dividend of 5½ per cent.

The Coal Market.—The opening up of traffic on the Elbe has caused a considerable increase in the coal trade of Bohemia. Since last week large quantities of coal have been despatched daily from Laube and Bodenbach for the export trade.

Cotton and Yarns.—A large number of influential cotton manufacturers in Austria have combined to form a syndicate. The principal cause of the creation of the syndicate is the negotiations which are being carried on between Austria and the German Empire. It is feared that some branches of home industry may be neglected, and the manufacturers have combined in order to make their influence felt.—The Vienna Chamber of Commerce has just received a communication from the Ministry of Commerce with reference to the numbering of yarns. This report states that the Ministry of Commerce has been informed by the Austrian Foreign Office that the marked falling off in the export of English cotton yarns is attributed by the English Foreign Office to the mischievous effect of incorrect descriptions of the goods when they are distributed by Austrian spinners. This view has already been put forward by the Manchester Chamber of Commerce. The English Foreign Office draws attention to the want of some legislation in Austria analogous to that of the Merchandise Act of 1887. The Chamber of Commerce and Trade and other competent authorities in this country have already expressed themselves in favour of the proposal of Mr. von Pacher for uniformity in the description of goods. The Vienna Chamber of Commerce has been requested to consider this subject again, and to make some proposals to the Ministry of Commerce with reference to it. The Ministry of Commerce further points out that it would be impossible to make a regulation similar to that contained in the Merchandise Act, according to which hanks of yarn must be made up in lengths of 840 yards, as the Austrian law of July 23rd, 1871 provides that all measurements must be made on the metric system.

Exhibition at Prague.—An Exhibition is to be held at Prague during the present year in commemoration of the first Trades Exhibition held on the Continent in 1791. The Exhibition, which will be open from May next till the 15th September, will comprise an international section of appliances for the prevention of accidents. This section will be divided into the following groups:—Machinery, chemicals, mining and foundry work, architecture, transport, lighting, ventilation, and fire engines. Full particulars may be obtained by applying to the Executive Committee, at 55, Winzelsplatz, Prague.

Exhibition of Carpets at Vienna.—An Exhibition of all kinds of ancient and modern carpets is to be opened next month in Vienna. The Exhibition will be held in the Imperial Austrian Commercial Museum, and full particulars may be had upon application to the secretary, 1, Börsenstrasse, 3, Vienna.

BRUSSELS, 31st March, 1891.

The Iron Market.—The iron market continues inactive. Business is very slack, and new orders are scarce at unremunerative prices. Constructive works and steel works have a better supply of orders than rolling mills, of which many are limiting their activity. Buyers refuse to deal at any increase of prices as far as concerns the cost of working. As has been already stated, it is intended to form an important society in Belgium in order to favour export trade. The directorate of this society was elected at Brussels on the 25th inst.—Some important contracts have recently been placed by the Belgian Government with home manufacturers.—An order for electric lighting apparatus for railway stations and for carriages has been placed with the Franco-Belgian Electric Lighting Company at Brussels.

The Coal Market.—There is little change in the coal market with the exception of a reduction in the price of *fines demi-grasses*. The demand for fuel, however, increases in the case of most industries, but little business is done at present in the hope that better prices may prevail. The stocks being now at a low ebb, the present output is soon taken off the market, although sugar and other industries have passed their period of greatest activity. The recent strikes at Seraing have caused some apprehension, and will make owners of coal mines inclined to maintain prices.

The Glass Trade.—The syndicate of glass manufacturers has decided to give some advantages to their customers by offering them from 1 to 2½ per cent. on their purchases. This will be the means of retaining their best customers. The proposal to stop some of the works meets with many difficulties, owing to the present conditions of manufacture.

Electric Lighting.—The Municipal Council of Antwerp are discussing a project for an installation of electric lighting, for which the motive power will be supplied by turbines. Different opinions are held as to the success of the scheme. The project for the electric lighting of Brussels makes little progress. It has been decided to construct a small circular electrical railway in the Bois de la Cambre. The scheme has been approved by Baron Jamblenne, who has worked out the technical details of the project.

Goods Traffic on the Belgian Railways. — The following statistics have been given with reference to the number of waggons employed on the Belgian railways from the 15th to the 21st of March during three consecutive years :—

	1889.	1890.	1891.
Coal and coke ...	20,611	22,679	21,223
Other goods	35,419	34,475	35,715
Railway service..	3,057	2,359	2,811
	59,087	59,513	59,749

The Belgian State Railways.—A considerable falling-off in the receipts realised last year by the working of the Belgian State Railways has been noted. The figures for 1890 show a deficit of 5,000,000fr. when compared with those of the two former years. Among the causes, according to the report just presented to the House of Representatives, is the great rise which has taken place in the price of fuel. From the figures given it appears that the average prices from 1887 to 1890 were, in succession, 4fr. 79c., 5fr. 80c., 6fr. 81c., and, lastly, 10fr. 97c. in 1890. Steel rails had also risen greatly in price. The ton of steel rails, which in 1887 cost on an average 108fr., has gone up each year in succession to 115fr. 65c. to 115fr. 52c. and to 132fr. 60c. last year. The last tender for Goliath rails, which are being more and more used on the Belgian lines, was 153fr. The long-distance lines will soon be laid with these rails, weighing 51 kilos., while the average rail formerly used was only 36 kilos. per metre. About 325 kilometres of Goliath rails have already been laid, which took 34,000 tons of steel.

DÜSSELDORF, 31st March, 1891.

The Iron Market.—The condition of the iron and steel market remains unaltered. Business in pig iron is still depressed. The Rhenish-Westphalian Pig Iron Union has been compelled by foreign competition to lower the prices generally from 1 to 4 marks. The following statistics are given with regard to stocks at the blast furnaces :—

	March 1st, 1891.	February 1st, 1891.
Best puddled iron	39,258 tons.	39,552 tons.
Ordinary puddled iron	5,901 „	6,498 „
Bessemer iron.....	9,467 „	12,297 „
Thomas iron	27,840 „	29,721 „
	82,466 „	88,068 „

The stocks of foundry pig iron at the blast furnaces amounted to 21,540 tons at the end of February, 1891, as compared with 23,245 tons at the end of January. The bar iron works continue to be not fully employed, and there is no improvement in the condition of the market for rolled iron. The business in thin sheets is still dull. Wages have been already reduced in the Siegen district. Works which are concerned in the production of railway material are briskly employed in carrying out new contracts. Machine works and iron foundries are generally well employed.

The Coal Market.—The demand for coals becomes more urgent every day. Railways and ironworks are trying to complete their stocks of fuel. The union of owners of gas coal mines has already ordered a rise of 1 mark per ton. It is to be feared that the export of coal will be considerably reduced through the anticipated rise in prices. The demand for coke has also largely increased.

AMSTERDAM, 30th March, 1891.

The Royal Engine Factory at Amsterdam.—The Royal Engine Factory at Amsterdam has been reconstructed as the Dutch Factory of Machinery and Railway Material, with a share capital of 1,280,000 guilders, and a mortgage loan of 920,000 guilders at 4½ per cent. From the prospectus, now issued, we gather that the works of the old company, that went into liquidation in consequence of heavy contract losses, will be taken over for 1½ million guilders, which is considerably under cost price. The new company will acquire a freehold plot of ground extending over 82,500 square metres in a favourable position, together with all buildings erected thereon and the stock they contain, valued at 226,000 guilders. The old mortgage debt will be cancelled by the payment of 100,000 guilders in cash and 480,000 guilders in new shares. Part of the new shares (600,000 guilders) bear a combined guarantee of 4 per cent. by the Holland Railway Company and of the State Railways Company, the essential condition being that the Dutch Factory of Machinery and Railway Material should give up shipbuilding as much as possible, substituting for it chiefly the manufacture of railway plant. Mr. C. H. Strumphler, at present manager at the well-known iron works of Messrs. Stork & Co., at Hengelo, will act as the director of the new undertaking. The result of these subscriptions so far has been that the whole of the guaranteed shares, and half the unguaranteed shares have been taken by the public. It may be noted that Queen Emma has put down her name for a considerable number of shares of both descriptions.

New Postal Law.—The Second Chamber of the States-General has passed the Government Bill for the better regulation of the postal service. Its provisions as to postage are extremely liberal. The cost of transmitting ordinary newspapers up to 40 grammes (say, a little less than 1½oz.) will be, for instance, only half a cent., which is under ½ of an English penny, whilst 150 grammes (say, 5oz.) of newspaper matter may be sent through the post for 1 cent., being under a farthing. The transmission of letters and samples will be proportionally cheap. "Copy" may be sent at "book rate," even if not accompanying any proof, or with a proof of other "copy." The Government opposed this clause, as facilitating fraud, but the amendment embodying it was carried by a large majority. The Bill has still to pass the First Chamber.

STOCKHOLM, 28th March, 1891.

The Gothenburg-Boros Railway.—Great interest is taken in this new railway, and plenty of capital appears to be forthcoming from various sources, the subscriptions having already reached about 2,000,000kr. The line will prove of considerable commercial and industrial value.

"Peat Coal" Manufacture.—When the question of transforming peat into a more convenient form of fuel was first raised it attracted much attention, but doubts as to the practicability of the process were freely expressed. The practical tests now going on at Omberg appear, however, to yield very satisfactory results. Several more manu-

Digitized by Google

factories will be started in various parts of the country during the forthcoming summer. It is thought that the production of "peat coal" will be advantageous to other industries.

INSURANCE OF WORKMEN AGAINST ACCIDENTS.—Attention has on previous occasions been drawn to the frequency of the workmen in industrial establishments being collectively insured against accidents in Sweden. The Fylgia Insurance Company has published particulars of 607 collective accidental insurances, which include 25,152 workpeople. Among these—

	Workpeople.
100 saw mills and other timber industries insure	7,150
27 manufacturing engineers and foundries	3,428
27 weaving and spinning mills	1,734
32 railways	1,348
13 lime and cement works	1,194
40 breweries	1,162
16 iron works	1,112
3 sugar works	854

THE SWEDISH ENGINEERING SOCIETY.—This Society recently held its annual general meeting at Stockholm. In the report special stress was laid upon the recent amalgamation of the two Swedish engineering societies. This arrangement is expected to greatly benefit all concerned. The members numbered 1,364 at the beginning of the present year, and during 1890 sixty-eight sectional and two general meetings have been held. The plan for the proposed large Stockholm Exhibition was discussed.

COPENHAGEN, 28TH MARCH, 1891.

THE AOLBORG PORTLAND CEMENT WORKS. — The Aolborg Cement Works will commence work in a few days, and is likely to become an important establishment. The capital is 800,000kr., and the buildings were begun about fifteen months ago. The engineering firm of Messrs. Smith & Co., Copenhagen, have had the contract for the works. The annual capacity is estimated at 125,000 barrels of cement.

LIGHT RAILWAYS ON THE DECAUVILLE SYSTEM.—Mr. Joh. Steenberg has applied to the Danish Government for concession to build and work narrow gauge railways on the Decauville system in various parts of the country. The first series of lines comprises thirty different railways, with an aggregate mileage of over 400 miles, and at a calculated cost of 10,000,000kr. It is intended that a large Danish company shall be formed to construct and work all these lines, with one central board of management.

THE BUTTER INDUSTRY.—The export of butter from Denmark during last year shows again a large increase as compared with that of the previous year, the figures being respectively 89,200,000lb. and 68,800,000lb. The increase in exports is not solely due to an increase in production, but to a decrease in the home consumption, in which margarine and cheaper imported butter have in many cases taken the place of good Danish butter. The import of foreign butter into Denmark during last year amounted to 18,700,000lb., or nearly 5,000,000lb. more than during 1889. Of the imported butter 15,000,000lb. have been used for home consumption, and the balance has been re-exported. Of the exports over 83,000,000lb. have gone to England.

MADRID, 30TH MARCH, 1891.

PATENT FUEL WORKS AT BILBAO.—A factory with the best plant is to be established at Bilbao for the manufacture of patent fuel. The pitch will be obtained from tar produced by the coke furnace of La Niscaya, which uses Carvé's system for the collection of the bye-products.

BILBAO COKE OVENS.—Messrs. Martinez Rivas are starting 90 coke ovens of the Coppée type, which will produce 200 tons per day, and will thus supply sufficient coke for their four blast furnaces. These furnaces, in addition to other bye-products, supply gas capable of raising steam for engines of 280 horse-power.

MERCURY MINES.—Mr. Gomez Hemas, a mining agent, has recently visited the neighbourhood of Llerena, and has acquired the right to purchase the three mines, Marzo, San Miguel, and Coronada, and work them in the meanwhile by paying a royalty. The cinnabar in these mines is visible for about one mile. Samples of the ore from a depth of 7 metres show 60 per cent. of metal on analysis, ore at a lesser depth gives 16 per cent., whilst mere outcroppings give 2 per cent. It is supposed that these mines have been acquired on behalf of a prosperous company, who are already working ores that yield less than 1 per cent. in other districts. In the mines of Almaden the cinnabar is found in sandstone, but at Llerena it is found in limestone.

ROME, 30TH MARCH, 1891.

NEW WAR VESSELS.—Messrs. Fratelli Orlando, of Leghorn, recently launched from their shipbuilding yard a large steel torpedo boat, the "Aretusa." This vessel is similar to the cruiser "Tripoli," and is provided with quick-firing guns. The engines, which were designed by Messrs. Orlando, and were executed at the works in their yard, are of 4,000 h.p. The vessel is to have a speed of 38 kilometres per hour. Two other cruisers of more importance, the "Umbria" and "Etruria," have just been completed at the same yard, and both vessels will be launched on the same day in April.

A NEW SUBMARINE GUN.—A submarine gun has lately been tried on the Lake of Como with success. The gun was submerged in the lake at a depth of 100 metres, and, notwithstanding the great pressure of the water, its charges succeeded in completely capsising a boat. Some further experiments are to be made on a larger scale.

THE RUBBER TRADE IN 1890.—The official Italian returns of the rubber trade in 1890 show a serious decrease in the imports, while there is slight increase as regards the exports, as may be seen from the following tables :—

	Quantity—Quintals.		Value—Lire.	
IMPORTS.	1890.	1889.	1890.	1889.
Rubber and gutta-percha :—				
Raw (solid and liquid)	3,089	3,051	2,471,600	2,135,700
In leaf, &c.	54	101	89,100	151,500
In threads, &c.	313	309	422,550	386,250
Otherwise worked	679	750	441,350	450,000
In tubes with metal	63	69	22,050	20,700
Mixed with tissues	683	650	341,500	292,500
In ribbons, bands, &c.	463	450	648,200	585,000
Electrical wires (covered)	169	219	88,725	120,450
Submarine cables, &c.	1,592	2,365	318,400	473,000
EXPORTS.				
Rubber threads	27	17	36,450	21,250
,, otherwise worked	260	290	169,000	174,000
,, in tubes with metal	17	39	8,500	17,550
,, ribbons, bands, &c.	152	104	212,800	135,200
Electrical wires (covered)	305	3	160,125	1,650

GAS AND ELECTRIC LIGHTING COMPANY.—At the general meeting of the Societá Anglo-Romana per l'Illuminazione di Roma Col Gas e Altri Sistemi, held recently, a dividend of 41 lire per share was declared, the total profits during 1890 amounting to £85,517. The company supplies electric light as well as gas. The electric plant consists of four dynamos driven by engines of 600 horse-power each, two dynamos with engines of 150 horse-power each, and one with an engine of 50 horse-power; three exciters, driven by engines of 40 horse-power each, steam being supplied by fourteen boilers of 164 horse-power each. The whole of this machinery has been erected by Messrs. Ganz & Co., of Budapest. The concentric high-tension cables used are 19,750 metres in length, and at the end of last year there were 143 transformers in use. The total number of lamps installed at the same date amounted to 11,156, of various powers, equal to 16,508 normal 16-candle lamps. There has been an increase of 3,478 lamps of various types, equal to 6,051 normal 16-candle lamps, during the past year. It has been said that this is one of the finest central stations on the alternating current system.

NEW YORK, 21ST MARCH, 1891.

NEW BILLET MILL.—The Ætna Iron and Steel Company, of Bridgeport, has placed an order with the Lloyd-Booth Company, of Youngstown,' for one 24in. three high billet mill of special design, to be used in its new steel plant, and two 22in. sheet trains. The billet mill referred to above was designed by Mr. C. W. Bray, secretary of the Lloyd-Booth Company, and it is claimed that it possesses some advantages not embodied in the present construction of billet mills.

NEW FURNACES.—The new furnace of the Rome Iron Company has been nearly completed. It is situated at New Rome, on the East Tennessee, Virginia, and Georgia Railroad, about two miles south of the city. The Chattanooga, Rome, and Columbus Railroad also runs near the furnace, over which the red ore will be hauled from Dirt Seller Mountain to the furnace. The plant is one of the best in the South, and the furnace will have a capacity of 80 tons per day. It is understood that two more furnaces will shortly be erected.

A COMPOUND LOCOMOTIVE.—A compound locomotive is being tried on the Southern Pacific Railway. It is a twelve-wheel freight engine, which was built as a simple engine at the Schenectady Locomotive Works, Schenectady, N.Y., and was put on the road about two and a half years ago. Under the supervision of Mr. H. J. Small, Superintendent of Motive Power, the engine has been compounded on the two-cylinder system adopted by the Schenectady Locomotive Works, including the intercepting valve designed by Mr. A. J. Pitkin, superintendent of the works. New cylinders have been applied, with the intercepting valve, receivers, &c. The engine has only recently been turned out of the shops. Tests will be made, states the *Engineering News*, as to its efficiency, especially to ascertain what the performance will be on mountain grades. In making the comparison, an engine will be used of the same weight and dimensions, with the exception of the cylinders. The following are the particulars of the compound engine: Cylinders, 20in. by 26in. and 29in. by 26in.; diameter of driving wheels, 51in.; diameter of truck wheels, 26in.; waggon-top boiler, 60in. diameter; firebox, 42¼in. by 104in.; 262 tubes, 2in. diameter and 12ft. 8in. long. Grate area, 30 square feet. Heating surface, 1,884 square feet. Driving wheel base, 13ft. 9in.; total wheel base, 23ft. 6in. Weight on driving wheels, 109,700lb.; weight on truck, 23,300lb.; total weight, 133,000lb. The tender is carried on 33in. truck wheels, and weighs 71,800lb. It carries 3,800 gallons of water and 6 tons of coal. The engine is fitted with the American Brake Company's brake.

ALUMINIUM.—The Pittsburgh Reduction Company has decided to offer pure aluminium at $1 per pound in any quantity. At this rate it is cheaper than nickel or German silver, and can be used commercially for many purposes, being nearly as cheap as copper. Metal below 97 per cent. and over 90 per cent. pure, containing no sulphur or phosphorus, for mixing with iron or steel, will be sold at 90 cents per pound.

THE OLSEN TESTING MACHINE.—Professor James Madison has presented the testing laboratory of Lafayette College, Easton, Pa., with an Olsen autographic automatic testing machine of 50 tons capacity, arranged for tension, compression, and transverse testing; a 1-ton cement testing machine; a full outfit of appliances for testing rock, cement, and mortar; a small machine for testing wire, cord, and cloth, and a Henning elongation meter, with micrometer callipers.

PHILADELPHIA, 20TH MARCH, 1891.

IRON AND STEEL.—The Standard Steel Company, near Chester, Pa., which recently shut down on account of a strike caused by the demands of the Brotherhood of Machine Moulders, has resumed work. The vacancies have been filled with members of the Iron Moulders' Union and non-union men. The Lehigh Iron Company, at Allentown, Pa., has reduced the wages of its employés 10 per cent. The employés of the Chesapeake Nail Works and the Central Works at Harrisburg are on strike because of a reduction in wages. Puddlers employed by the Glasgow Iron Company and the Pottstown Iron Company, at Pottstown, have accepted a reduction of wages from $3·75 to $3·50 per ton. The rolling mill at West Hamburg, operated by the Pottsville Iron and Steel Company, has resumed work. There are 125 men employed. Puddlers receive $4 per ton, although it was announced before shutting down that their wages would be reduced to $3·50.

HARBOUR IMPROVEMENT AT PHILADELPHIA.—In appropriating $300,000 for continuing the harbour improvement, on the 3rd inst., Congress imposed certain restrictions which made it impossible under the rules of the Engineer's Department to make any contract in accordance with specifications, and it was necessary, therefore, to reject all tenders. New specifications are now prepared, and if satisfactory to the War Department the contract will be awarded within thirty days. The harbour improvement will consist not merely in the removal of the Delaware Islands, 17,000,000 cubic yards of earth, but also in the restoration of the original proportions of the river by an advance of both the Pennsylvania and New Jersey shore lines. Of the material thus removed, 7,000,000 cubic yards are to be used to fill up League Island (navy yard), 1,500,000 cubic yards for the Camden (N.J.) shore, and 500,000 cubic yards for the Philadelphia shore.

RAILROADS.—It is announced that there will be a complete change in the management of the Louisville, New Albany, and Chicago Railroads, by which a large amount of traffic will be thrown into the hands of this company. Senator Brice and General Thomas have agreed to furnish a sum of money, for which they will be given control of the road. These gentlemen control the Lake Erie and Western Railroads, and are prominent in the Richmond Terminal, both of which roads will by this arrangement secure an entrance into Chicago.

THE NEW YORK CENTRAL RAILROAD.—The New York Central and Hudson River Railroad has taken possession of the Rome, Watertown, and Ogdensburg Railroad under a perpetual lease, which gives the former 700 more miles entirely in New York State, and an unbroken line from New York City to the St. Lawrence River, besides several important branches.

THE OIL WELL SUPPLY COMPANY.—The purchase of the Elba Iron Works and the Continental Tube Works, which was recently effected by the Oil Well Supply Company, will enable the latter in future to manufacture its own tubing.

NAVAL.—The work of constructing guns for the new war vessels is rapidly progressing at the Washington Navy Yard. There are at present 72 guns in various stages of construction. The two 10in. guns for the armoured cruiser "Maine" are nearly finished, and the two 12in. guns for the coast defence will be finished in three months. There are many guns of 6in. and 8in. bore. The Navy Department has invited proposals for the construction of the protected steel cruiser of 7,300 tons displacement, which is to be made entirely of materials of home manufacture.

ENLARGEMENT OF MESSRS. CRAMP'S SHIPYARD.—The foundry and machine shops of Messrs. J. P. Morris have been purchased by Messrs. Wm. Cramp & Sons, shipbuilders. Hitherto Messrs. Cramp have furnished sufficient work to keep five separate foundry and machine companies constantly employed.

ELECTRIC SUSPENSION RAILWAY.—The Davy Electric Suspension Company has been organised at Springfield, Ill., with a capital stock of $10,000,000, to build and operate a system of suspended carriages for the transportation of passengers and freight.

QUICKER SPEED BETWEEN PHILADELPHIA AND NEW YORK.—By an arrangement of troughs at Plainfield, the trains on the Philadelphia and Reading Railroad between New York and Philadelphia will be enabled to take water without stop or change of engines at Bound Brook, which has heretofore been the practice. These troughs are 1,500ft. in length, and enable the locomotive to scoop water while running at full speed. Steam pipes are provided on both sides of the trough to prevent freezing in cold weather. The distance between New York and Philadelphia is 90 miles, and by this arrangement the Reading Railroad is enabled to effect a saving of five minutes between the two cities.

Digitized by Google

THE INSTITUTION OF CIVIL ENGINEERS.

At a meeting on the 24th ult., the President, Sir John Coode, K.C.M.G., being in the chair, a paper was read "On the Reception and Storage of Refined Petroleum in Bulk," by Mr. W. T. H. Carrington, M.Inst.C.E. The author described at length both the appliances necessary for dealing with petroleum in bulk and the methods of using them.

Mains forming the Pipe Lines.—These were usually of wrought iron, and were from 6in. to 8in. in diameter; the length of line seldom exceeded 500 yards. The connection with the steamer was by means of a flexible tube made of canvas and indiarubber, or canvas alone. The pipe line was constructed so that it could be readily cleaned out, and was also fitted with draw-off cocks. The valves used were preferably steam-valves. A "dirt tank" was provided, into which any cloudy oil was pumped, and the impurities allowed to settle. The pipe line entered the storage tanks either at the top or through the side near the bottom—the author preferring the former arrangement. If the latter plan was adopted an internal radial pipe was used, which could also be employed for suction purposes. It was, however, better to keep the delivery and suction pipes independent. The pipe line was tested to a pressure of 60lb. per square inch, the usual pressure when oil was being pumped varying from 20lb. to 40lb. per square inch. The rate of delivery was from 600 to 1,000 barrels per hour.

Tanks.—The size of tank to be used depended greatly on the nature of the work to be done. If the oil was of uniform quality, a number of large tanks of about 15,000 barrels capacity might be provided, and a few small ones; but a depôt dealing with many different classes of petroleum should be fitted with a number of small tanks and a few large ones. The size of the tanks was also governed by the bearing power of the ground. The foundations on rock or shingle needed only to be levelled; but on soft yielding ground many plans had been resorted to, such as—placing the tank directly on the ground, which rendered the bottom plates liable to rust; setting it on a layer of concrete, which must, however, be very thick and heavy to be of any value; making a foundation of chalk and ballast, which was often successful; piling to the underlying hard ground and supporting the tank on a gridiron formed on the top of the piles—this answered well, but was expensive. On rocky ground tanks might be carried on concrete walls, thus giving access to the seams from underneath. The author had also used timber walls resting on a timber platform as a support, where the foundation was soft. Large tanks were always made of a cylindrical section, with a flat bottom, and a domed, conical, or flat top. The diameters varied from 80ft. to 30ft. The author preferred iron as a material. On soft ground precautions must be taken to prevent the collapse of the tanks in the event of their sinking unevenly. This was better done by increasing the thickness of the lower tiers of the circular sides, than by the use of tee-bars or struts. The plates should be as large as possible, so as to lessen the number of rivet holes, which might lead to leakage. Where the roofs were domed or conical, they were of thin material, about No. 12 B.W.G., and were either carried by trussed frames, or by tee-bars, radiating from a central column. In hot climates flat tops were used, and made to carry a depth of about 6in. of water, in order to reduce the internal temperature, and therefore the evaporation of the oil. Either two or four manholes were provided in the roof, both in order to obtain access to the inside, and for ventilating purposes; occasionally others were placed in the sides near the bottom. These were convenient, but, in the author's opinion, should, if possible, be avoided, as they constituted a point of weakness. Tests were applied at two stages of the construction: First, when the bottom and first circular tier were riveted up, at which period the tank should be supported on wood blocks some little distance above the ground. It was then filled to a depth of 2ft. with water, and the bottom, being made perfectly tight, was coated with tar or varnish. The second test was made when the work was finished. It was necessary to clean the inside very carefully before the oil was put in; for this reason it was either painted with white zinc paint, or the whole internal surface was wiped with oily cloths. The petroleum, when delivered into the tanks, had to be measured in order to determine the quantity received. This was done by taking soundings at a number of points through suitable doors and manholes, placed for the purpose in the roof, a steel tape, fitted with a slider of ebony, being used for the purpose. In order to determine the quantity of water sent over with the oil from the discharging ship, a water-searcher, invented by Messrs. Horley & Sedgely, was employed. On being lowered to the tank bottom it brought up a section of the liquid, showing the depth of water and sediment lying there.

Delivering Arrangements.—The withdrawal of the petroleum for delivery from the storage tanks was done either by gravity, where the situation permitted it, or by pumping, and it was delivered into tank-barges and waggons, or into barrels. In the latter case it was pumped into a small tank, about 10ft. above the ground, from which it ran into the flexible pipes carrying the automatic cocks which were arranged so as to cut off the supply when the oil rose to a certain level in the barrel; with them one man could fill upwards of 50 barrels per hour. The usual number delivered daily from a large wharf varied from 1,000 to 1,500 barrels. Before being filled they were carefully examined, and, when necessary, coopered and made sound, and then, in order to make them perfectly oil-tight, about a quart of hot glue was put into each, and the barrel turned about in such a manner as to cause the liquid to cover the whole surface. After being drained they were put into a store to dry, and were then ready for use. The painting was done by boys with large brushes, but in some cases the barrels were dipped bodily into a tank containing a quantity of paint. A brush worked by steam had also been lately introduced, and was said to answer well. The weight of the barrel and the brand of oil it was intended to contain was also stencilled on it. Barrels formed a strong and convenient package, and though their use was becoming less general, owing to the introduction of tank waggons and carts, it would be probably a long time before anything more convenient for retail purposes would be found.

SOME DETAILS IN MARINE ENGINEERING.*

(*Concluded from page* 297.)

The Machining of Crank Shafts.—It is somewhat common to find it stated in specifications of triple-expansion marine engines that the built crank shaft shall have its main bearings turned when all the three sections of the shaft are bolted together. If the only point of accuracy that was worth attaining were the condition of having the axes of all the six main bearings truly in one line, the above would be a very wise condition to impose upon the engine builder in the specification. This, however, is far from being the case. It is just as important that the crank pins should run well as the main bearings, and to this end it is necessary that the axes of the crank pins should be truly parallel with the axis of the body part. Most modern crank shafts are made interchangeable, and many of them reversible as well. If this condition is to be fulfilled in the best possible manner, it is necessary that the faces of the couplings should be truly square with the axis of the body part. And if the simplest method of interchangement be provided for without loss of accuracy in the result, the axis of the couplings should be truly in line with the axis of the body parts, at the same time that both the previous conditions are fulfilled. If any one will give a little thought to this matter, he will find it is not sufficient to bolt three sections of a shaft together, leaving the body parts rough, and turning the whole when thus bolted together.

To fulfil the conditions above mentioned it is necessary that each individual section of the shaft should be true in itself. And it is a much more difficult and costly matter to make three individually accurate shafts, all precisely like one another, and accurately bolt them together so that the body parts are truly in line, than to bolt together three rough shafts and finish the body parts all at once. The method on which the writer proceeds in this matter is to finish the pins before shrinking together and leave the body parts rough turned. Then fix one individual section of the shaft in the lathe on the main body part centres, setting it accurately by the pin; that is to say, the shaft is revolved into four positions—top, bottom, right, and left. In these four positions a spirit level is laid on the finished pin, and the shaft moved in the centres until it will revolve in such a way as to show the axis of the pin is truly parallel with the axis on which the shaft is revolving. The shaft is then completely finished. Its main bearings are turned, the peripheries of its couplings are turned accurately to a dimension, and the faces of its couplings are surfaced down. When the three sections of the shaft have been thus treated they are set together by the peripheries of the couplings in V blocks, the bolt holes are bored and the shafts bolted together. The shaft is then brought as a whole again into the lathe, not, however, to be *turned*, but simply for examination, to prove the accuracy of the work. If the shaft is out of truth, that is, if the whole six main bearings are not running truly on one axis, the fault is obviously in the bolting together. To take a cut off any part would be to make the shafts no longer duplicate, and would undo what so much care had been spent in previously doing. The writer would not have called attention to this matter had it not been now so common to see the other method asked for in specifications, and which in his opinion only secures one good quality in the shaft out of many that are equally desirable.

Piston Packing.—There is, perhaps, no mechanical detail about an engine that has a greater influence on the economical use of steam than a thoroughly satisfactory piston packing. Piston packings have been designed in almost every conceivable form, and the patent specifications relating to the subject are perfectly bewildering. The writer does not propose to weary the meeting with a criticism of the various piston packings in use, and, indeed, such criticism would require a long paper to itself. There can be no doubt, however, that many packings are designed without a proper knowledge of what it is that is required of them when put to work. A packing that will do quite satisfactorily in a low-pressure cylinder may be unsuitable for the medium-pressure cylinder, and a packing that would suit a medium-pressure cylinder might not do at all in a high-pressure cylinder. The converse of this, however, is not necessarily true, for a packing that will be suitable for a high-pressure cylinder is likely also to be suitable for all lower pressures.

The writer has given close attention to this subject during the past ten years, and after many experiments made to discover the simplest possible packing that would answer in high-pressure cylinders, he finally patented, in 1886, the form of packing he now has the pleasure of placing before the Institution, and which, after a very extended trial and use, has more than satisfied his most sanguine expectations. Some engineers having tried various forms of packing in their high-pressure cylinders, with the result that the latter have been bored out perhaps ¼in. larger in diameter on a voyage, or corded in a shocking manner, have finally fallen back in despair upon the ordinary Ramsbottom rings, and as these have certainly the quality of producing a pretty cylinder, they thenceforward swear by them alone. Ramsbottom rings, however, wear at a considerable rate, and, worse than that, they pass steam from one side of the piston to the other and reduce the economy of the engines.

The writer has found considerable misapprehension existing in the minds of many engineers with whom he has come in contact regarding the physical conditions under which piston-packing exists when at work in the cylinder. For instance, many appear to suppose that, if the packing rings and their tongue pieces are so carefully fitted to the piston as to be practically steam-tight, no steam will get past them into the recess in the piston behind the rings. A moment's consideration, however, should show that if we have, for instance, 150lb. pressure on one side of a piston, and say 50lb. on the other side, it will be absolutely impossible for any perfection of fitting to be capable of retaining the space behind the packing rings for days and weeks together at atmospheric pressure. If it were possible to insert a tube into this ring space when the engines were at work and take a diagram, it would represent a sort of horizontal figure 8, and if the rings very freely pass steam, the upper ring of the figure would nearly reach the 150lb., and the lower limb the 50lb. which we have assumed to represent the pressures on the opposite sides of the piston. The more and more perfect the fitting of the rings, the more the figure 8 would flatten towards a straight line; and therefore the best possible condition, with the most perfectly fitted rings, would be a diagram showing a constant pressure of say 100lb. per square inch behind the rings. This really is the beginning of the subject in designing high-pressure packing rings, and it is this pressure of something like 100lb. per square inch on the internal surface of the rings, forcing them against the cylinder walls, that is the main factor to be dealt with. When this fact is recognised, nothing can seem more absurd than the placing of heavy springs behind the rings, forcing them against the wall, and so augmenting this already heavy pressure instead of reducing it. Indeed, in a vertical engine, a piston packing that is not allowed to run so far over the bell mouth at the ends of the cylinder as to receive a blow from the steam on its outer surface sufficient to drive it into the piston recess, requires no springs whatever behind it, and is infinitely better without any, for the very simple reason that when it is free from any connection with the body of the piston it acts as a floating packing, or, in other words, it is laterally independent of the piston, and follows the line of the cylinder walls only, regardless of where the piston may be. This floating quality is of very high importance in view of the cylinder retaining its circular form, as when it is absent the tendency of the piston to put pressure on one side or the other is communicated to the packing rings, and the cylinder is worn out of truth accordingly. The principal office of springs in a piston packing should be either to reduce the pressure on the walls of the cylinder due to the steam pressure behind the rings, or to minimise the effect of this pressure. The latter is perhaps the easier course to adopt, and in the packing under description this is done by making the upper and lower rings of the packing bear upon a wide surface on the junk ring and piston flange, and applying a very heavy vertical pressure against these surfaces proportionate to the steam pressure acting on the inner surfaces of the rings. The breadth of surface adopted is 2in. in all pistons from 18in. diameter up to 80in. As the leading idea in this piston packing is the attempt to secure the greatest universality of form, whilst complying with the varying physical conditions of pistons of all pressures and sizes, we may remark that the first point of universality gained is the breadth of bearing surface on the junk ring and piston flange just alluded to. In the next place, each of the two rings is made the same height as it is in breadth—viz., 2in. by 2in., the vertical height of the ring space, therefore, becoming 4in. This, it will be observed, gives a plain rectangular section of ring, and which has important advantages over any bevelled or otherwise shaped section, inasmuch as its natural tendency is, when opening out to a larger diameter of cylinder, to expand in one plane; whereas other sections, having more breadth at the upper than at the lower edge, are incapable of expanding in one plane, because one edge expands more freely than the other, with the result that the ring curls up, and requires re-bedding as soon as the cylinder begins to wear. That this rectangular section, 2in. by 2in., can be made satisfactory throughout so large a range of diameters as 18in. to 80in., and through so large a range of pressures as obtains between the high-pressure and low-pressure cylinders of a triple or quadruple engine, might at first sight seem surprising, but the explanation is simple—viz., that the higher the pressure the stronger and stiffer the rings require to be, and this variation in stiffness comes naturally with the lessening diameter whilst retaining the same cross section.

To the all-important question of the form and application of the springs much attention was given, with the result that this also was reduced to the most complete universality of size and form for pistons of all sizes and pressures ordinarily in use in triple and quadruple expansion marine engines. A spring of the common helical form 2 3/8in. in length and 1in. in diameter is found capable of meeting every condition where a spring is wanted, or ever likely to be wanted in any piston. To provide the heavy pressure that is necessary between the junk ring and piston flange, holes are bored in the upper surface of the lower ring, and in the under surface of the upper ring, into which these little helical springs are inserted. The distance apart of these springs around the circle can of course be varied, and this variation in distance apart, together with the variation that can be given in

* Paper read by Mr. Thomas Mudd before the Institution of Naval Architects on the 20th ult.

Digitized by Google

the amount of compression of the springs, is found sufficient to meet all the differences required between high-pressure pistons and low-pressure pistons. It is, indeed, only by taking advantage of these natural adjustments that it becomes possible to make one form of spring suit every class of piston.

The great pressure used in pressing the packing rings by means of these springs against the junk ring and piston flange, amounting as it does in high-pressure pistons to many tons, and augmented as it is by the steam pressure between the rings, has the effect of preventing the rings being forced unduly against the walls of the cylinder by means of the steam pressure behind them, and thus it is found that new engines fitted with this piston packing can make a voyage round the world without doing more than dress out the tool marks in the cylinder. One of these springs is usually inserted tangentially at the joint of each ring, with just sufficient pressure to hold the ring from sliding down the cylinder with its own weight. The form of the ring fortunately lends itself to an easy provision in case of emergency. That is to say, if from any cause the pressure on the vertical springs was released, the rings would become worn without the engineer in charge being aware what was going on, and he might in such circumstances open the cylinders in a far distant port to find the rings so slack as to be incapable of being forced out to the cylinder wall by means of the tongue spring. Holes are therefore drilled horizontally into the inner side of both the rings, so that the same springs can again be applied in such a way as to press against the body of the piston and force the ring out till it reaches the cylinder. This is intended entirely as an emergency provision, and would only be used to enable the rings to bring the ship home, when a new set of rings would be required, as when thus used they have lost their floating capabilities, and are not what they were intended to be.

It is with this as with all matters connected with engineering—viz., experience alone can decide the practical value of any particular device—and on this subject it is satisfactory to be able to state that out of more than 250 pistons of all pressures that have been fitted with these packing rings there has never yet been one to renew, and there is not one, within the writer's knowledge, that has worn more than ⅛in. open at the joint since it left the shop. The absolute universality of the spring for high-pressure, medium-pressure, and low-pressure cylinders of every size and every pressure, will strike every engineer as being a great point gained, because the spare springs put on board of any individual ship will suit any piston and any position of spring, and, indeed, if any engineer on board of a ship requires springs when he happens to have no spare ones, he is likely to meet in any ordinary port in the world some other ship having the same maker's engines, and which may have on board spare springs that he may borrow. Besides, the spring itself being of the most ordinary and simple form, merely representing a coil of steel wire, can be dealt with or made by any ordinary engineer sufficiently well for any emergency.

There is another view of the case that should not be overlooked. Many piston packings appear to run fairly well so long as there is no steam jacket in operation around the cylinder, and it is very common to hear chief engineers remark that they dare not put steam in their jackets, because the cylinder would immediately become cut by the packing rings. This is a serious loss, and it is one that need not exist. With a sufficiently heavy pressure between junk ring and flange there is no fear at all of the packing rings cutting, and with the pistons under description it is the writer's practice even to run new engines on their trial trips with the high-pressure jacket at full boiler pressure.

Cylinder Construction.—The use of high-pressure steam, with its consequent high temperature, led the writer to adopt the method of placing the high-pressure cylinder of three-crank triple engines in the middle between the other two, with the object of reducing, as far as possible, the loss of heat by radiation from the steam when at its highest temperature. In carrying this policy out still further, he places all the valve chests between the cylinders, thus leaving the forward and after ends of the cylinder structure merely plain semicircles. He further provides the high-pressure cylinder with a steam jacket, and carries the receivers or steam chests of the two lower cylinders round the outside of this jacket so as entirely to enclose it. In this way the high-pressure cylinder and its steam chest nowhere come in contact with the atmosphere, except at top and bottom. The cylinder structure by this method has a very straightforward plain exterior, which is very easily covered all over to a depth of 2½in. with fossil meal non-conducting material, held in place by sheet steel. It will be observed that the jacket, although small in extent, is practically a double jacket, for its inner wall is radiating heat into the cylinder, and its outer wall is equally giving off heat into the receivers. That this jacket in ordinary work is very actively operative is proved by the trials recently made by Professor Kennedy and his scientific staff on board the s.s. "Iona," in connection with the Research Committee on Marine Engine Trials of the Institution of Mechanical Engineers, when this single jacket was found to be condensing about 4·55 per cent. of the total feed-water. Professor Kennedy's report to the Institution of Mechanical Engineers, and which is at the present time under consideration by that Institution, appears to indicate further that the writer's expectations of steam economy arising from this arrangement of cylinders and jackets is to a high degree realised, as on a sixteen hours' trial the engines of the "Iona" were found to be giving one indicated horse-power on 13·35lb. of feed-water per hour. The writer is of opinion that amongst the contributing circumstances leading up to this satisfactory result, there are none of greater importance than the arrangement of the cylinder structure, and the application of the piston packing rings which he has had the honour of describing.

SHIPBUILDING NOTES.

On the 17th ult. the s.s. "Oil-rivers," a handsome steel screw steamer, which has been built by Sir Raylton Dixon & Co., Middlesbrough, to the order of Messrs. Elder, Dempster, & Co., of Liverpool, for the African Steamship Company, took her trial trip from the Tees. The dimensions of the vessel are:—Length over all, 324ft. 9in.; breadth, 39ft.; depth, moulded, 27ft. 5¼in., with a deadweight capacity of about 4,300 tons. Her machinery, which has been fitted by Messrs. T. Richardson & Sons, Hartlepool, with cylinders 23in., 38in., 61in., by 39in. stroke, accomplished 11 knots on trial trip, and gave general satisfaction.

On the 24th ult. the first of the three steam hopper barges for the Corporation of Preston, recently launched from the yard of Messrs. Wm. Simons & Co., of Renfrew, was tried on the Clyde with satisfactory results. The measured mile was run on the Gareloch, where the vessel attained a speed of fully nine miles per hour, which was in excess of that contracted for.

Notices of Meetings.

THIS WEEK.

Institute of Marine Engineers.—Friday, April 3rd, at 7 p.m. Annual general meeting.

Geologists' Association.—Friday, April 3rd, at 8 p.m. Papers to be read: "Notes on the Sections on the New Railway between Nunhead and Shortlands; and on the New Railway from Grays to Upminster," by Mr. T. V. Holmes; "The Eocene and Oligocene Beds of the Paris Basin," by Messrs. G. F. Harris and H. W. Burrows.

NEXT WEEK.

Society of Engineers.—Monday, April 6th, at 7.30 p.m. Paper to be read: "A Trial of a Refrigerating Machine on the Linde System," by Mr. T. B. Lightfoot, M.Inst.C.E.

Society of Chemical Industry.—Monday, April 6th, at 8 p.m. Papers to be read: "The Analysis of Illuminating Gases" and "The Products of Checked Combustion," by Professor Vivian B. Lewes.

Cleveland Institution of Engineers.—Monday, April 6th, at 7.30 p.m. Paper to be read: "Observations on Various Matters of Interest to Engineers in the United States of America," by Mr. J. Head, M.Inst.C.E.

Royal Institute of British Architects.—Monday, April 6th, at 8 p.m. Sessional meeting.

Institution of Civil Engineers.—Tuesday, April 7th, at 8 p.m. Ordinary meeting. Paper to be read: "The Cost of the Generation and Distribution of Electrical Energy," by Mr. R. E. B. Crompton, M.Inst.C.E. Monthly ballot for members and (at 9 p.m.) reception by the President and Council.

Royal Victoria Hall.—Tuesday, April 7th. Lecture on "Minute Things in Nature," by Professor Rupert Jones.

Institution of Electrical Engineers.—Thursday, April 9th, at 8 p.m. Paper to be read: "The Design of Multipolar Dynamos," by Mr. W. B. Esson.

PRICES CURRENT, 1st April, 1891.

Quotations at per ton, unless otherwise specified.

Zinc Sulphate	ton	7	10	0	—	.....		

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Chemicals: The Easter holidays have interfered with business, and there is nothing of interest to report since our last, the markets being practically unchanged. Sulphur continues in exceedingly strong demand. The articles controlled by the United Alkali Company are all moving off steadily.

HOME INDUSTRIES.

LONDON, 2nd April, 1891.

The Money Market.—The end of the first quarter of the year, as well as of the official financial year, has, as usual, caused a somewhat sharp demand for money, while the supply has been correspondingly diminished. Call money has consequently been fairly dear this week, commanding in some cases 3 per cent. A good deal of borrowing has taken place at the Bank of England, owing to the deficiency in the supply in the outside markets. In consequence of the recent holidays, business this week has been on a restricted scale, but the markets are showing less absolute dulness than before the holidays, and there has been a welcome movement upward in American and Canadian railway securities, induced largely by the conclusion of a species of traffic alliance between the Vanderbilt interest and the Canadian Pacific. Home railways continue inert, the cold weather during Easter having restricted travelling, and so made little impression on the traffic returns. Foreign bonds have been dull and drooping, financial difficulties in Italy, political events in Bulgaria, and the obstacles encountered by Portugal in the effort to secure a new loan combining to depress values in this department. Argentine issues have declined in consequence of a fresh rise in the gold premium at Buenos Ayres. The market for miscellaneous and industrial securities has been quite idle. Copper shares are neglected, but there is some activity in Indian and the better class of South African gold shares.

The Junior Engineering Society.—At a meeting of this Society held on the 20th ult. a paper was read by Mr. H. Young, Jun., on "Iron from the Ore to the Casting." The author said that cast iron was not known in this country until the fourteenth century. The ironfields were then in Sussex, and the balustrade which surrounds St. Paul's Cathedral was cast in that county at the Lamberhurst furnace, and, according to the account books, cost £11,202 0s. 6d. Recently new railings of similar design had been made by Messrs. H. Young & Co. as an enclosure to the new statue of Queen Anne, and had cost £110, or £1·3 per foot run, as compared with £8·14 per foot run in the case of the balustrade. Considering the increased price of materials and of labour at the present time, it was surprising that the cost of production had so greatly diminished. The author proceeded next to an investigation of the character of the various ores. Roasting, weathering, and the general preparation of ores before entering the blast furnace were fully treated, and the methods adopted for the utilisation of slag and of blast furnace waste gases were discussed. The capillary structure of slag wool was shown by aid of a microscope. The chemical changes taking place in the blast furnace were explained, as were also the chemical and physical properties of the different grades of pig iron and their crystallisation. In illustration of the paper, a very complete collection of specimens, which had been kindly furnished by the Bowling, Carron, Caulder, Tipton Green, and Weardale companies, and by Messrs. F. Jones & Co. and Messrs. D. Anderson & Son, was exhibited. A practical demonstration of founding constituted an interesting feature of the lecture.

The Telephone Service in London.—We are glad to learn that an association of subscribers to the telephone has been started for the purpose of securing a cheaper and more efficient service of telephones in London. Having regard to the expiration of the patents, the charges for the use of the Post Office Telephone Exchanges in the country have been reduced, so that subscribers within a quarter of a mile of the exchange pay £8 a year; within half a mile, £10 a year; three-quarters of a mile, £12 a year; and one mile, £14 a year. No reduction, however, in the charges to London subscribers has been made by the United Telephone Company. The association seeks, in addition to a lowering of the charges, a more effective service. This would be attained by the use of the double-wire system, by which alone the voice can be clearly heard in London.

Emigrants' Information Office.—According to information just issued by the Emigrants' Information Office, 31, Broadway, Westminster, S.W., this is the best month in the year for emigrants to go to Canada, where, besides the usual demand for female servants, there is now a demand for farm hands and for men in the building trades, which is likely to continue during spring and summer. The Canadian Government now offers for the first time bonuses of $15 to the head of a family, and half that amount to his wife and grown-up children, if he settles on land in the North-West or in British Columbia. In Australasia the harvest is now over, but there is still a demand for female servants, miners, navvies, farm hands, dairymen, ploughmen, bushmen, general labourers, and men who understand pruning fruit trees and nursery work. Such men and women will, under certain conditions, get free or reduced passages to Queensland and Western Australia. In South Africa carpenters, masons, bricklayers, and other useful mechanics, navvies, and female servants are in demand, and may, under certain conditions, obtain reduced passages to Cape Colony and Natal. Farmers and fruit growers will find openings in all these colonies, and may obtain reduced passages to Western Australia, and in certain cases free passages to Natal. Emigration is strongly discouraged to South America at the present time. The existing political and social conditions of the Argentine Republic and Chili are very unfavourable to emigrants from Great Britain or from Ireland, while Brazil, to which free passages have lately been advertised, and with regard to which special warnings have lately been issued by the office, is a tropical country, and in almost every respect ill-suited to such emigrants.

The Camera Club.—The fifth annual conference of the Camera Club, at which there will be an exhibition of members' pictures and of lantern slides, is to be held at the rooms of the Society of Arts on the 7th and 8th inst., under the presidency of Captain Abney, F.R.S.

Business Announcement.—The business of Mr. Napier Prentice, electrical engineer, Stowmarket, has been amalgamated with that of Messrs. Easton & Anderson, Limited, of Erith and London. Mr. Prentice has removed his factory and staff to Erith.

Congress of Hygiene.—The Council of the Society of Arts, acting under the provisions of the Benjamin Shaw Trust, have offered two Gold Medals, or two prizes of £20 each, to the Executive Committee of the Congress of Hygiene and Democracy, for any inventions or discoveries of date subsequent to 1885, exhibited at or submitted to the Congress, and coming within the terms of the Trust. Under the conditions laid down by the donor, these prizes are to be offered for new methods of obviating or diminishing risks incidental to industrial occupations.

MANCHESTER, 2nd April, 1891.

The Iron Trade.—The market for iron in this district is very dull, and any sales which are being made are only small. Pig iron is going steadily into consumption, but speculation is entirely at a standstill. Bar iron is very slow of sale, and prices are maintained with difficulty. Some of the brands of marked iron are proportionately worse than the commoner qualities, and generally the outlook in this department is very bad. Steel plates are being steadily taken up, but the whole tone of the market is lifeless.

The Engineering Trades.—Owing to the holidays there is a lull in business, and very little new work is to hand. The general impression is that there is likely to be less demand in the immediate future for machinery of all kinds, a variety of causes contributing to that result. In the meantime work is being actively proceeded with. Most firms have plenty of orders in hand, and, unless the present state of affairs is interfered with by the fifty-three hours question, a fairly good year is probable. Several large engines are being constructed for the new mills in course of erection in this neighbourhood, but there are many signs that the condition of the spinning trade is not very satisfactory. Spinners have had to contend during the year with a bad quality of cotton, and it is not likely that the prosperity enjoyed by them will last in the face of the enormous increase in the number of operative spindles during the past two years. The increase in the number of new mills is therefore likely to receive a check which must react upon engineers. Toolmakers up to the present have little reason for complaint, and their prospects continue to be good. Cotton spinning machinists are fully engaged, and there are still considerable orders being placed. Messrs. John Hetherington & Sons, Limited, have recently purchased a plot of land, containing four acres, adjoining their works, for the purposes of extension, their business having grown rapidly during the past three or four years. The Mills Patent Boiler Company, Limited, have acquired the extensive premises recently owned by Messrs. Barningham & Co., Limited, and are adapting them for the manufacture of this specialty, for which they have a large demand, principally for London and the Continent.

Railway Fares.—The Manchester, Sheffield, and Lincolnshire Railway Company, in pursuance of the policy agreed upon at the last meeting of the shareholders, commenced yesterday to run trains composed only of first and third class carriages. The fares have been revised so as to be similar to those current on the Midland Railway Company. The change, however, does not apply to a number of the local trains, where second-class carriages are extensively used.

Business Announcement.—The works and offices of Messrs. Meldrum Bros., engineers, have been removed from the Cathedral Yard to more commodious premises at the Atlantic Works, City Road.

The Linen and Jute Trades.—There has been little business during the past week. Orders are fairly numerous, considering the season. Cotton towels, which are stocked in the linen departments, have been inquired for largely, and linen descriptions have been taken off the market to a fair extent. Stair cloths are slow, oilcloths having superseded the linen article to a large extent. Union makes (flax and jute) meet with a steady sale. The damask trade is quiet, no feature of special importance being noticeable in connection with this department. The linen dress linings are again meeting with a moderate sale, but they have not, of course, interfered with satteens. There is no appreciable change in quotations, which keep steady all round, both for yarns and cloth. The shipping trade is quiet, except in a few instances. From Canada there has been more inquiry, and hopes are entertained that that market will shortly improve. It is impossible, however, to hold out any hope of a complete revival for some time to come, as the affairs of wholesale houses on the other side of the Atlantic are still greatly disarranged. Trade with South America is extremely slow. For Australia there is more business, and prospects are improving. Yorkshire crashes and other standard makes sell steadily. Yarns are dull here. Linen threads are inquired for to a satisfactory extent, and agents for well-known makes have little ground for complaint as to the condition of the home trade.

Fire Extinguishing Apparatus.—A public trial was made of Noble's patent pumping arrangement, to which reference has been previously made, in the yard attached to the chief fire station in Manchester, on the 24th ult. This apparatus consists of a pump contained in a suitable frame and operated by the foot of the person using it. The stream of water thus obtained is ejected by a hose, and it was shown that a considerable quantity could be thrown for several feet. The appliance is portable, and can be employed as a domestic fire engine, and is also available for washing windows. Generally the trial was considered to be a satisfactory one.

GLASGOW, 2nd April, 1891.

Minerals.—The pig iron market opened on the 31st ult. The price advanced fractionally. Coal shipments are again active. Last week the total shipments amounted to 121,439 tons, an increase of 17,239 tons over the preceding week, and 1,820 tons over the corresponding week last year. The prospects of the foreign coal trade seem fairly good. In spite of the heavy loss of shipments during the strike, the totals of shipments are now so large that much of the loss is likely to be made up.

General Trade.—It is generally felt that we have now entered upon a period of depressed trade. The cause of this seems to be the fact of a large falling off in the effective demand. Some local industries have been injuriously affected by the McKinley Tariff Act. The iron and steel trades, which had been abnormally inflated during the period of activity on foreign and colonial railway construction, are now suffering from temporary slackness. Two years ago also there were several important engineering enterprises going on both at home and abroad, and there is a lull in the promotion of these. This falling off in demand has not yet seriously affected the rate of wages, but it has caused much irregularity of employment.

Scottish Railways.—Although the railway men are dissatisfied with the terms offered by the North British Railway directors, there is a strong impression that they will delay taking any steps until the result of the Select Committee is known. It is generally understood that the Government are practically pledged to legislate on the question, and the men seem to be inclined to wait for the promulgation of the Bill. Besides, the strain upon the staffs of the railways is diminishing from other causes. Traffic returns show a decrease, and the press of work is not nearly so great as it was last year. The men are therefore less severely tasked than they were in the months preceding the strike of December last.

Shipping.—The "City of Rome" will begin sailing from the Firth of Clyde to New York this month. The large vessel will find berth accommodation in the James Watt Dock, Greenock. This dock, which has not been hitherto very successful, will derive much benefit from this new departure of the Anchor Line Company. The State Line steamers, having been purchased by Messrs. J. & A. Allan, of the Allan Line, will begin sailing between Glasgow and New York this month. The price paid by Messrs. Allan for the vessels and the goodwill of the business is said to have been £70,000. Unfortunately the shareholders will receive very little on the completion of the liquidation, if there is not even a deficit. The £5 shares of the State Line were being offered in Glasgow this week at 6d. each. The Gulf Steamship Company is about to start a line of steamships between Glasgow and Australia. The first sailing will take place at the end of April. The freight market is extremely quiet. San Francisco, 40s. for December, and 41s. 3d. for earlier months. The following fixtures are reported:—Cardiff to Venice, 9s.; Calcutta to U.K., 34s. 6d. The unfixed sailing tonnage is put at 7,000 tons.

Shipbuilding.—Though new orders are coming in slowly, there is still a good deal of work in progress in the Clyde yards. At Dumbarton the s.s. "Scott," for the South African Service of the Union Company, is now approaching completion. The vessel is intended to reduce the passage to fourteen days. It is hoped that the speed may reach at least 19 knots at sea. The beam of the vessel is unusually large. The vessel will be ready for sea about the beginning of May. The other work in the yard consists mainly of small vessels and some barges for the Irrawady flotilla, for which Messrs. Denny have supplied all the craft. Messrs. Blackwood & Gordon, Port Glasgow, have just received an order from the Ceylon Steamship Company, through the managers, Messrs. Walker Brothers, Bishopsgate Street, London, for the building and engineering of a steel screw steamer of about 600 tons and 700 i.h.p. for passengers and cargo service round the coast of Ceylon. They have also received an order from Messrs. Hill, Gomes, & Co. for an additional steamer for trading in Brazil, somewhat similar to, but shorter and less speedy than, the twin-screw steamers "Iris" and "Satellite" recently finished by them for this company.

The Future of the North British Railway.—The fall in the stock of this company has been quite phenomenal. In August last the ordinary stock stood at 74⅜; in January, during the strike, it touched 49¼; in February, after the close of the strike, it dropped to 48 5/16; and in March it fell to 41. The uncertainty

Digitized by Google

of the effect upon future dividends of the changes which it is now obvious must be effected in the management of the company, combined with the determined "bearing" of the stock, thrust it down. It must be noted, however, that at the prices of last summer the stock was abnormally high, and that only disguise of the real condition of the company kept the stock at its then level. At the present prices of the combined stocks, 111, the stock is much nearer its normal value then it was at 154 during August last. There does not seem any valid ground for pessimism as to the future of the company. It is quite unrivalled in many districts, and has possessed itself of the leading through routes. With more adequate detail administration, and, perhaps, also the investment of some additional capital in land and rolling stock, it will be fully able to take advantage of its really splendid opportunities.

THE GLASGOW TRAMWAYS.—The Glasgow Tramway Company recently procured permission from the Court of Session to alter their articles of association so far as to permit the employment of mechanical power on the tramway lines. The lease of the lines to the company expires in 1894, and it is improbable that it will be renewed on terms similar to those of the present lease, or, indeed, on any terms whatever if the present attitude of the Corporation be maintained. It is unlikely, therefore, that the company will take any steps towards exercising the powers they have obtained.

(From our own Correspondents.)

LIVERPOOL, 1st April, 1891.

ENGINEERING AND SHIPBUILDING.—Most of the shops and yards on both sides of the river have been closed for the Easter holidays; some of them, however, have been compelled not only to work during the holidays, but to work overtime on account of urgent work and repairs. It is satisfactory to note the continued prosperity in the trade, with good prospects for many months to come. During the Easter holidays more than 30,000 passengers crossed the Woodside Ferry, the number last year being 38,689, and in the previous year, 41,390.

LIVERPOOL AND THE RIVAL PORTS.—Although the question of Milford becoming a rival port to Liverpool periodically crops up, and is as regularly ridiculed by many Liverpool men and by the financial papers, many prominent and able men consider that there is real cause for alarm, and that Mr. Greville's scheme is within a measurable distance of being fully realised. They cannot overlook the fact of the splendid natural advantages of Milford, and the circuitous approach to the mouth of the Mersey and the difficulties connected with the bar. Liverpool is undoubtedly more favourably placed as regards the railways, but Milford is nearer London and has many other natural advantages over Liverpool.

LIVERPOOL ENGINEERING SOCIETY.—At a meeting of this society on the 18th ult., under the presidency of Mr. F. Hudleston, an adjourned discussion took place upon Professor Hele Shaw's paper on "The Education of an Engineer." The President urged that the preliminary education of an engineer should be as broad as possible, and valued highly the study of higher mathematics. Mr. G. Farren described the Continental system of training with reference to the Government schools in Holland. Mr. H. H. West advocated the old-fashioned principle of five or seven years' apprenticeship, to be followed, if possible, by two years of college training. Mr. Higginson spoke in favour of six months' work in the shops during the summer, and six months' training in the college during the winter. Mr. Turner thought that the student should first see actual work in the shops and office, and afterwards study the scientific principles which underlie what he has seen practised.

SHEFFIELD, 1st April, 1891.

IRON AND STEEL.—Active operations were suspended at all the iron and steel works in this district on Easter Monday and Tuesday. There are sufficient orders to keep manufacturers fully employed for some time to come. Orders for railway material and rolling stock continue to come in steadily, and manufacturers are well employed. Messrs. Ashbury's Railway Carriage Company have orders for 1,600 carriages and waggons, mostly for the home railways. Makers of ordinary merchant iron are complaining of a falling off in the demand, and find it difficult to maintain prices. Pig iron of all descriptions has declined to unremunerative prices, and all surplus iron is being stocked in the hope of better prices. Steel castings appear to be in less demand than for some time past, and in the smaller castings there is much competition from outside, and even from Germany. In very heavy work, the local houses are fully employed on castings and forgings for general marine and mill work. In boiler and ship plates there is not much business at present. The "Purves" flues, of which Messrs. John Brown & Co. are the sole makers, are coming largely into use, and this firm have in consequence again extended their works.

COAL.—Prices for fuel of all kinds continue high. Mr. G. B. Walker, of the Wharncliffe Silkstone Colliery, who has just returned from a visit to Australia, has recently given some interesting particulars with reference to coal and mining generally in Australia. Mr. Walker is of opinion that some reduction in the cost of winning coal in England must be effected, and suggests the more general use of coal cutting machines.

BARROW-IN-FURNESS, 1st April, 1891.

HEMATITE.—The business done in hematite pig iron during the week has been very small, and makers have not been able to effect any transactions of moment, as they are still undersold by holders of hematite warrants. The latter are being sold as low as 47s. 6d. per ton net cash, and makers cannot possibly sell at less than 50s. per ton for Bessemer iron in mixed numbers net f.o.b. unless they sell at a loss. The make of iron has been further reduced, but the weak market has caused weak holders of stock to sell, and while this has the satisfactory effect of clearing stocks it is also checking makers' sales.

STEEL.—Business in the steel trade is very quiet, although prospects are better, both in the rail and in the steel shipbuilding material department. Orders are fairly numerous, but the mills are not working full time. Some heavy contracts for steel rails are offering, but at low prices, and makers are still firm in quoting £4 12s. 6d. for heavy sections net f.o.b. There is some hope of a brisk future in the steel shipbuilding material trade, as some very good shipbuilding contracts will probably come to Barrow. New and powerful engines are being built by Messrs. Galloway, of Manchester, for the present heavy rail mill of the Barrow Steel Company, and when these are erected and in working order the company intend to roll the heavier and larger class of plates, which are now in brisk demand alike for shipbuilding and boiler purposes. It is confidently expected that when the new light mill is put down great economies will be achieved in the Siemens-Martin steel trade of Barrow, and that an impetus will be given to the manufacture of this class of steel in Furness.

AMERICAN WAGGON BUILDING AT BARROW.—The Tubular Frame Wagon Company have now acquired possession of the Vulcan Steel and Forge Company's works at Barrow, and already have 100 men in their employ. They propose to build bogie trucks, 35ft. long, on the American principle, each to carry 30 tons, and they have selected Barrow as the *locale* of their operations because their trade will be largely on foreign account, and because Barrow offers many advantages for shipping purposes. It is expected by Mr. M. R. Jefferds, the general manager of the company, that they will produce and deliver 20 trucks per day, and it is proposed at once to put down plant for the manufacture of steel tubes, malleable castings, and grey iron castings, so as to concentrate all the work on the premises. The timber required will be directly imported from America. Workmen's dinners are to be provided free by the company, and it is expected in a short time 500 men will be employed, while ultimately the works are to employ 2,000 men. The directors are:—Colonel Church (chairman), Colonel J. T. North, Alderman Fenton (London), and Mr. R. N. Fowler (Leeds). The new industry promises to be of considerable importance to the trade and port of Barrow.

MIDDLESBROUGH, 1st April, 1891.

PIG IRON.—The iron market is still very dull. Scarcely any business is being done, and prices are only nominal. The quotations are no stronger than those given in our last report. For prompt f.o.b. deliveries of No. 3 G.M.B. merchants ask 39s. per ton, but this is more than buyers are prepared to give, and they generally offer 38s. 6d. Cleveland warrants are nominally 38s. 9d. per ton cash sellers and 38s. 6d. cash buyers. Grey forge is quoted at 38s. 3d. per ton, but some has been sold for 38s. There is more available for sale on account of the stoppage of the local forges, and also because Scotland has been taking less. East Coast hematite pig is quoted at 53s. per ton for mixed numbers. It is not expected that stocks will show any decrease this month, as the local forges are working irregularly on account of the holidays. Shipments were a little better last week, and amounted to 16,110 tons. The shipments of pig iron for March amount to 66,435 tons, against 70,499 tons in February and 60,683 in March, 1890. Of the 66,435 tons, 38,876 tons went to various parts of England and Scotland and 27,559 tons went abroad. As compared with the same month last year, the home consumption has increased more than double, and the foreign dwindled down to little more than half.

MANUFACTURED IRON AND STEEL.—There is no change to report in the finished iron and steel industries, and there is little or no demand. Common iron bars can be bought at £5 12s. 6d. per ton, less 2½ per cent. f.o.b. Heavy steel rails are £4 12s. 6d. net.

COKE.—The demand for coke is not so great, owing to the blowing out of several furnaces. The price quoted is from 14s. to 15s. per ton, delivered at the furnaces.

WORK AND WAGES.—The adjourned meeting of the Cleveland ironmasters' and the blast furnacemen's representatives was held yesterday. It will be remembered that at the previous meeting the masters gave the men the option of accepting 12½ per cent. reduction or reviving the sliding scale which regulated their wages up to the end of June last. The men's representatives were only prepared to accept 5 per cent. reduction, but afterwards stated that they would accept the sliding scale subject to certain alterations. The employers were not prepared to entertain these suggested alterations, and the meeting was adjourned until the 8th inst., in order that the delegates might consult the men. In order to protect the masters' interests, the men will receive a fortnight's notice to quit their work.

SUNDERLAND, 1st April, 1891.

THE SHIPPING AND COAL TRADE.—The freight market continues depressed, but there is an improved prospect in the local coal trade, as the prolonged Silksworth Colliery dispute has been settled. Imports fluctuate considerably, six cargoes being received last week, as against twenty-three cargoes in the previous week. Coal shipments amounted to 69,984 tons during the past week, an increase of 8,045 tons, about two-thirds of the total being for coastwise orders. Other shipments were barely up to the average.

SHIPBUILDING.—No additional contracts are being booked, and inquiries are not so numerous. During the past month six steamers of 10,417 gross register tons have been launched, making a total for the first quarter of the current year of seventeen vessels of 35,563 tons. A steamer of 4,000 tons, which has been built at Mr. James Laing's Deptford Yard, has been sold to the local Neptune Steam Shipping Company, Limited.

NEWCASTLE, 1st April, 1891

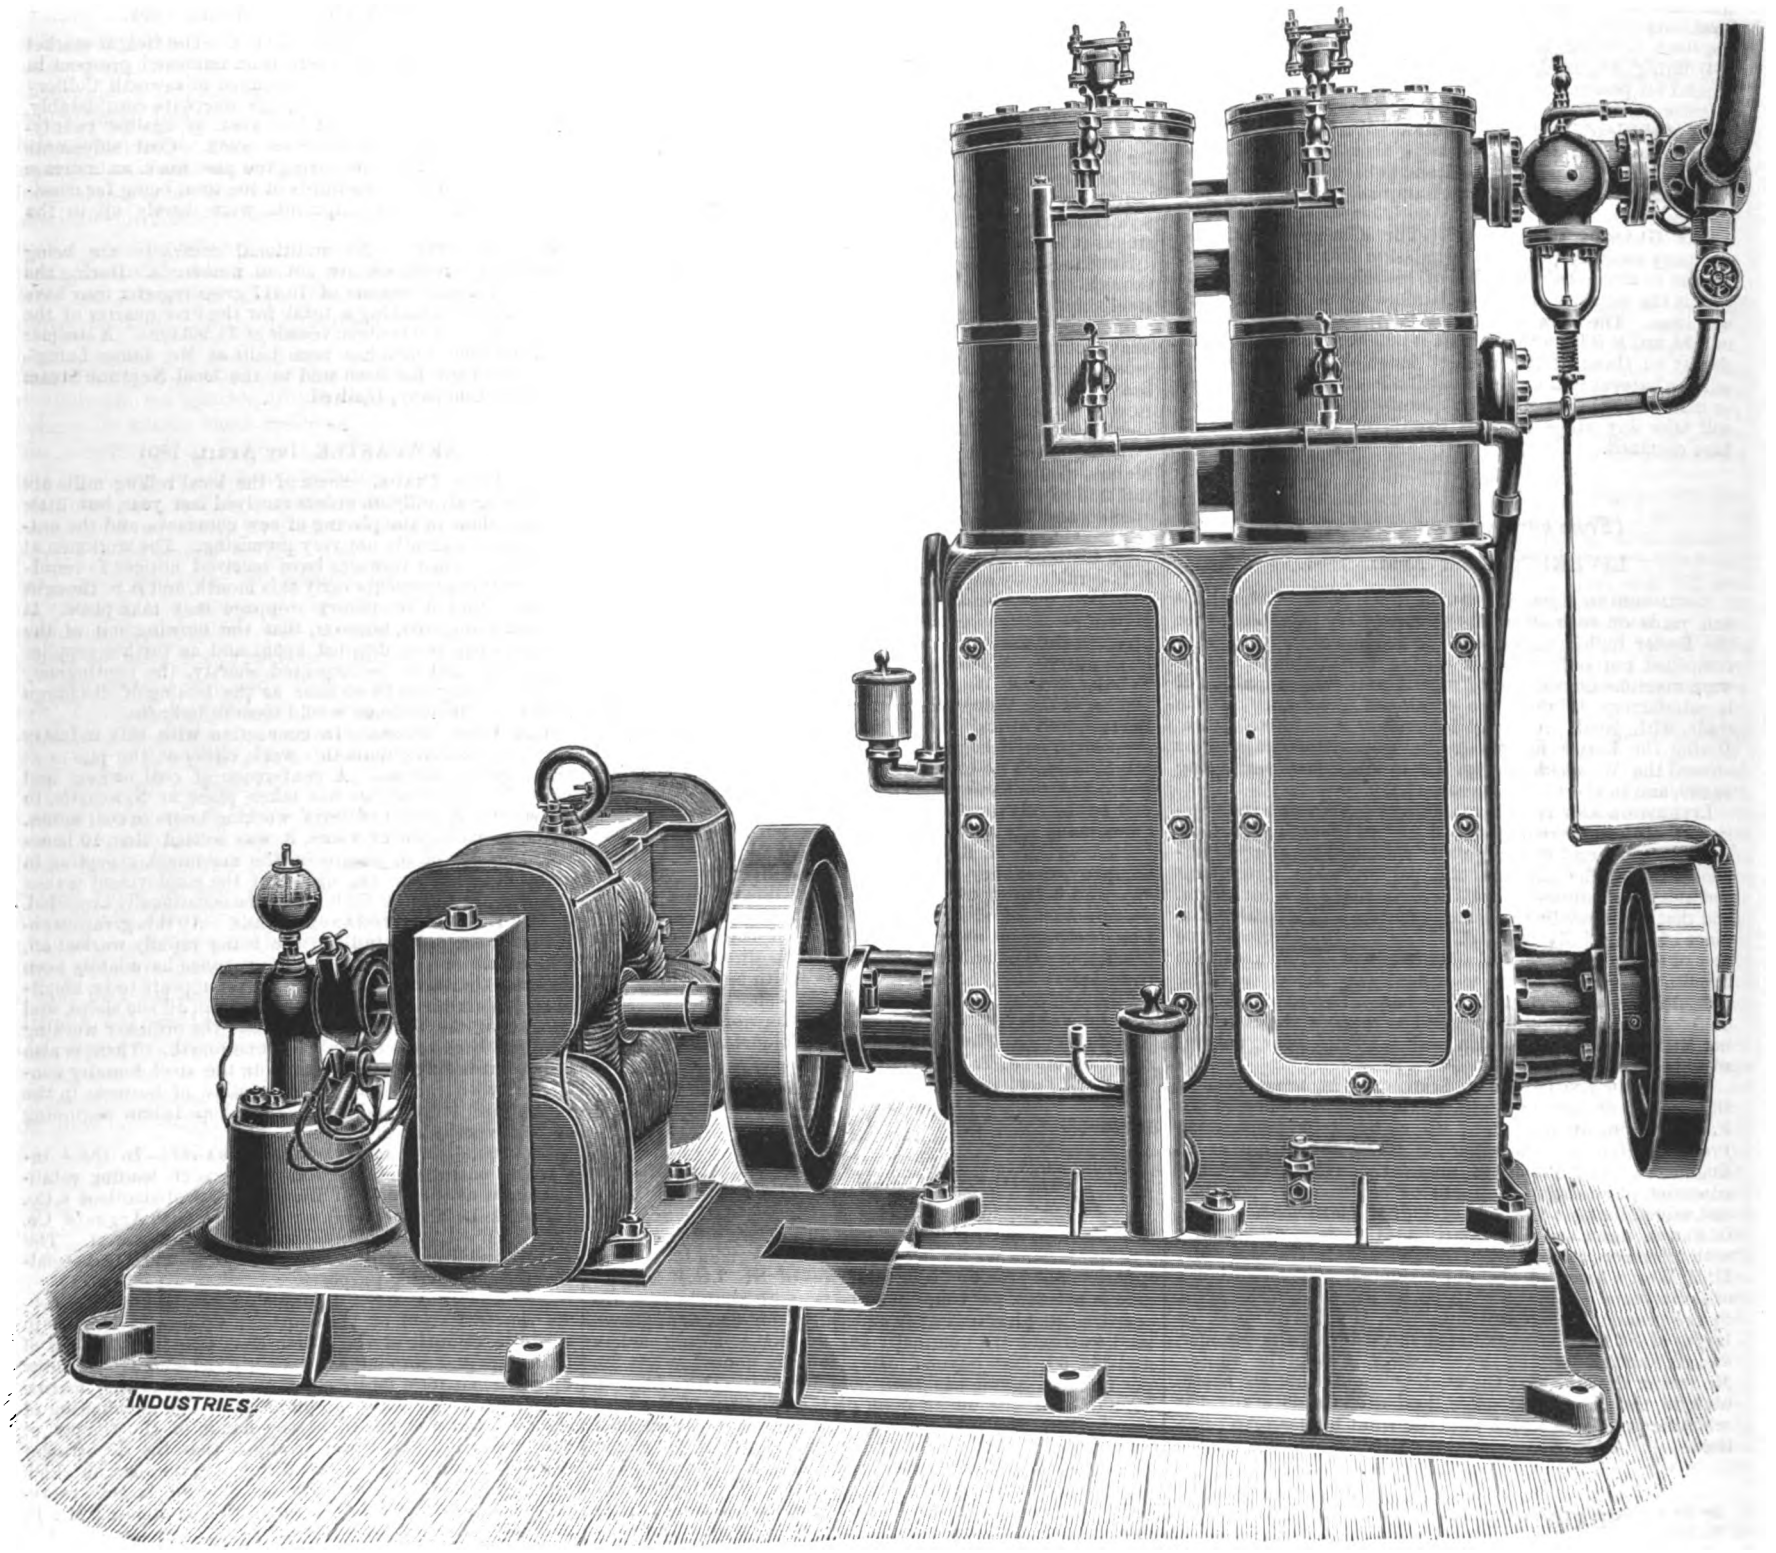
THE IRON TRADE.—Some of the local rolling mills are kept going steadily on orders received last year, but little is being done in the placing of new contracts, and the outlook is consequently not very promising. The workmen at the Walker blast furnaces have received notices to terminate their engagements early this month, and it is thought probable that a temporary stoppage may take place. It has not transpired, however, that the blowing out of the furnaces has been decided upon, and as further supplies of ore are said to be expected shortly, the contingency spoken of may not be so near as the issuing of discharge notices to the workmen would seem to indicate.

THE COAL TRADE.—In connection with this industry very little is being done this week, either at the pits or at the shipping staiths. A conference of coal owners and miners' representatives has taken place at Newcastle, to discuss the question of boys' working hours in coal mines. After an exchange of views, it was settled that 10 hours per day should in future be the maximum, excepting in certain cases where the nature of the employment makes it necessary that this limit should be occasionally exceeded.

THE ELSWICK ORDNANCE WORKS.—At this great establishment the orders in hand are being rapidly worked off, and as no new contracts of importance have lately been secured the advent of a slack period appears to be inevitable. Workmen are being paid off from all the shops, and in one of the leading departments the ordinary working staff has been reduced by fully one-fourth. There is also a distinct falling off of briskness in the steel foundry connected with the works, and the state of business in the boiler-yard, forges, and engineering shops is now beginning to be adversely affected.

LEATHER AND INDIARUBBER TRADES.—In these industries business is fairly active, and such leading establishments as the works of Messrs. E. & J. Richardson & Co. (Elswick Leather Works), and Messrs. Geo. Angus & Co. (St. John's Leather Works) are briskly employed. The last-named firm continue to do a large business in specialties for engineering purposes.

APPOINTMENT OF A PROFESSOR OF ENGINEERING.—At the invitation of the Durham College of Science in 1887 the Council of the North-East Coast Institution of Engineers and Shipbuilders appointed a committee to draw up a scheme for a department of mechanical and marine engineering and naval architecture. The nomination of the professor was placed in the hands of the Council of the Institution, and it was arranged that the department should be managed by a committee of specialists, on which the Council of the Institution should be largely represented. The Council of the Institution nominated Mr. R. L. Weighton, M.A., who has within the last few days formally accepted the chair. For seven years Mr. Weighton has held the appointment of chief draughtsman at Messrs. R. & W. Hawthorn, Leslie, & Co.'s works at St. Peter's, and is the author of important papers on "The Compound Engine, viewed in its Economical Aspect," and on "The Normal Indicated Horse-Power of Marine Engines and Boilers."



DUNDEE, 1st April, 1891.

PRICE OF COAL GAS.—A committee of the Dundee Gas Commission, which has been giving some attention to the most economical mode of purchasing coal for the manufacture of gas, has come to the conclusion that the purchase of the higher-priced cannels is much more expensive than the judicious use of lower-priced coal. The value of richer kinds of coal as gas producers was found to be very much overstated, and in one case to the extent of £1 2s. 10d. per ton.

DUNDEE SUBURBAN RAILWAY.—It is reported that a contract has been made with Messrs. Best & Son, Edinburgh, for the construction of the suburban railway, at a cost of over £300,000. The railway will be about four miles and a half in length. The deepest cutting will be 40ft. There will be one viaduct, 50ft. high and 100 yards in length, and twenty-two bridges.

THE CROMPTON-CHANDLER STEAM DYNAMO.

General View.

THE CROMPTON-CHANDLER STEAM DYNAMO.

The rapid growth of central station work is developing the manufacture of quick-running engines and large direct-coupled dynamos. The above illustration shows a double-crank compound engine of the Chandler type driving a Crompton direct current dynamo. The engine can indicate 6½ horse-power, and run at 500 revolutions per minute. The dynamo has a ring armature of the type which Messrs. Crompton have used so successfully. It is 15½in. diameter and 5in. axially, the radial depth of the discs being 3in. The armature is built up of thin discs on a cast spider. This not only makes a good mechanical armature, but allows thorough ventilation. The maximum rise of temperature after six hours' run is only 30° Fahr. The output is 55 volts and 100 amperes. The particular steam dynamo we now illustrate is one of several sets being sent to Australia. The total weight of engine, dynamo, and bed-plate complete is 22 cwt. This type is being largely introduced for shiplighting, several having been fixed on Messrs. Cook & Sons' Nile steamers and elsewhere, where they have done very well.

THE SIBERIAN RAILWAY.

It seems that the long-talked-of Siberian Railway is at last about to be commenced, as an Imperial ukase has been published directing the expropriation of the owners of the land required for the construction of the Vladivostock-Grafsraja section, and it is stated that the engineer and the workmen by whom the line is to be constructed have left Odessa for Vladivostock, where the works are to be begun. This section of the line is to be pushed on as quickly as possible, probably as much with a view to military contingencies as for any other object. We are informed that the Chinese authorities are considerably alarmed at the prospect of the railway being completed in that district, and that probably one effect will be the making of another line by the Chinese in order to facilitate the transport of troops in case of need. Siberia embraces a great variety of climates, and has great mineral and agricultural resources. The total length of the line will be 4,810 miles, and the cost about 32 millions sterling. If permanent bridges are built across the great rivers the cost will be much greater. When completed the railway will have most important commercial results by opening up the immense resources of Southern Siberia. A large portion of it will run through millions of acres of the finest virgin soil, and through countries abounding in mineral and vegetable wealth. Moreover, it will enable Russia to compete more successfully for the Japanese and Chinese carrying and import trade, and goods which are now sent by sea to Europe will be carried overland. Probably, however, it will not much affect the sea traffic, as the development of trade will be so great that there will be enough for both routes.

Advertisements intended for insertion on the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to ensure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 3RD APRIL, 1891.

MR. GOSCHEN'S CURRENCY PROPOSALS.

THE chief interest in the public finance of the year is centred in the proposals of Mr. Goschen as somewhat vaguely indicated in his recent speech at Leeds. The speech is a very interesting and important economic deliverance, but much additional information is necessary ere adequate materials are available for forming a judgment upon it. The leading point which Mr. Goschen made was that in his view the recent Baring crisis brought the country within measurable distance of serious and widespread commercial disaster, and that not so much because of the magnitude of the commitments of the house of Baring as because of the slenderness of the stock of gold available for prompt use in the discharge of international obligations. It happens that foreign Governments make London bankers their depositories for large sums, and in this way they acquire a control over the money market of an occasionally embarrassing nature. Mr. Bagehot pointed out long ago the difficulty in which the very existence of such deposits placed us. The German Government, for example, has invariably a large sum standing at its credit in the books of one of the London joint stock banks. This sum must, along with the other deposits of the bank, be employed, otherwise the bank could not exist. The money, as a matter of fact, becomes merged in the general funds of the bank, and the amount available for the prompt liquidation of the liabilities of the bank is, as is customary, lodged in the Bank of England. The balances of the joint stock banks are as a rule maintained at a high figure in the books of the Bank of England, but money represented by these balances again finds its way into the market through the discounts of the Bank. Thus, under normal conditions, the regulation of the rate of discount operates as an efficient check against the diminution of the balances in the Bank of England. An abnormal strain, however, such as a demand from Germany or from Russia for the prompt payment of £1,000,000 to £2,000,000 in gold, comes first upon the bank with whom the money had been deposited, but finally upon the bankers' bank—viz., the Bank of England—and unless the demand has been anticipated that Bank suddenly finds its stock of gold depleted, and is compelled to restrict its discounts in order to encourage the inflow of gold again. The requirements of our own Government can be ascertained with almost mathematical exactness, but those of foreign Governments depend upon circumstances, which are not always so accurately known, and although, as a matter of fact, the power wielded by Russia and Germany over our money market is seldom exercised in a sinister fashion, it is possible at times for either of these Powers, even unwittingly, to cause the greatest financial disturbance. Without exaggerating in any way the importance of having a large stock of gold in the country, it is quite clear that unless we have very ample gold reserves the ordinary course of banking business may be characterised by serious crises, which speedily affect circles beyond the financial circle immediately concerned, and indirectly, but still potently, affect commercial and industrial circles generally.

Mr. Goschen is thus really acting in the interests of the whole community in putting his shoulder to the wheel in order to effect some means of rendering financial crises less frequent in occurrence, and to provide some automatic method of meeting them when they actually occur. Although there is a large class of people who live upon the fluctuations of the money market, and to whom even a crisis brings profit, the interest of manufacturing business is always in the direction of certainty in prices, and therefore in the reduction of monetary fluctuations within the narrowest possible limits. There can be no doubt that the existence of an ample reserve of gold in the Bank of England gives, reasonably or unreasonably, a feeling of confidence to the money market, and through it a feeling of steadiness to the whole commercial and industrial organisation of the country. On the other hand, a small gold reserve and heavy liabilities produce a feeling of uneasiness which is contagious, and which speedily affects almost every one in some degree. The primary object of Mr. Goschen's proposals is, then, so to increase the gold reserves at the Bank of England as to afford against panic a security of a permanent character. The question is—Can this be done? Mr. Goschen's idea is that there is a quantity of gold circulating in the pockets of the people, and therefore unavailable in quantities on an emergency, which might be replaced by bank-notes, so far as the pockets of the people are concerned, and that the gold coin so displaced would then find its way to the Bank of England, there to form a second gold reserve, and so constitute a security against panic. The method which Mr. Goschen proposed has indeed been pressed upon the attention of bankers for years by an eminent Scottish banker, Mr. Charles Gairdner, manager of the Union Bank of Scotland. A few months ago that gentleman read a paper at Edinburgh to the Institute of Bankers in Scotland, in which he employed substantially the same phrases as Mr. Goschen used at Leeds to describe the danger of the existing inadequate reserve, and proposed substantially the same remedy. The position is briefly this. We hold a smaller quantity of gold absolutely than the United States, or Germany, or France, and a vastly smaller quantity relatively to our internal or external trade as compared with those countries. The United States hold over £60,000,000 of bullion under central control and about £82,000,000 in the national banks, a large part of this amount being by law incapable of depletion. The Bank of Germany holds about £40,000,000 in gold and silver; the Bank of France holds about £95,000,000. Against these figures London, the banking centre of the world, the pivot upon which the whole structure of credit turns, possesses a central reserve of only £24,000,000. Even if there be added to this the gold in the provincial banks of England, Scotland, and Ireland, amounting to under £20,000,000, we have only £44,000,000, of which only about £20,000,000 in gold is really available as a national reserve. There is a very obvious advantage in the possession of an ample reserve. It contributes to the stability of public confidence, and consequently to the avoidance of panic and to the prevention of great extremes of fluctuation. Although there are other causes for the steadiness of the Bank

Digitized by Google

rate in France as compared with the Bank rate in England, besides the retention of a large metallic reserve, it is very remarkable that during the past seven years there have been only seven changes of the French Bank rate, between the limits of 2½ and 4½ per cent., while during the same period there have been sixty-two changes of the English Bank rate, between the limits of 2 and 6 per cent. In order to increase the reserve, not temporarily, but permanently, Mr. Goschen proposes to issue £20,000,000 or £30,000,000 in £1 and 10s. notes, and to keep as a special national reserve the metallic money it represents at present in the pockets and tills of the public. Mr. Goschen is indubitably right in saying that if the gold so withdrawn from circulation and replaced by paper were simply added to the existing reserve it would speedily disappear. It would be driven out of the country by the irresistible operation of Gresham's Law, which has defeated the efforts of so many currency reformers. Although Mr. Goschen recognises this danger, he has so far promulgated no definite proposal for providing against it. For unless some provision be made for the permanent retention of this gold in the coffers of the Bank of England, there would be no additional reserve; on the contrary, it is conceivable that it might even be smaller than before. Again, if the gold be permanently locked up in the Bank of England, incapable of being employed save in the case of war, as is the German military treasure in the fortress of Spandau, of what avail would it be in an ordinary financial crisis? It must, however, be admitted that, so unreasoning is the commercial mind during financial crises, that the mere knowledge of the existence of a store of gold, even though the store were unavailable save by exceptional action of the Government, might suffice to impart a feeling of confidence. The important points, after all, are that in a time of financial strain, solvent houses should be enabled to borrow upon substantial security, and that thus the area influenced by the strain should be restricted as much as possible. The obvious danger is that the formation of this national reserve might encourage risky finance among large houses. At present, with the grave warning of the recent crisis before their eyes and the serious consequences which the crisis entailed still apparent, the largest houses have a natural fear of the results of injudicious speculation. It would be a great misfortune if, in seeking to protect the public against financial panics, the course of action which leads to these were in any way encouraged. Apart from the question of the formation of a second reserve, the issue of 10s. and £1 notes can hardly fail to be a distinct advantage, although there is much to be urged against the former being issued in place of silver while this metal is so greatly depreciated. The obvious result of the withdrawal of, say, £10,000,000 in half-sovereigns, and the issue of 10s. notes against a nominal amount of £10,000,000 in silver, would be a large profit to the Government, and a corresponding nominal loss to the public. This issue might, indeed, result in much practical inconvenience unless these notes were made legal tender up to any amount instead of being made legal tender only to the amount of 40s. It is, however, rather premature to criticise Mr. Goschen's proposals until their details are more fully disclosed.

WORKMEN'S HOURS OF LABOUR.

A Parliamentary Return has just been issued by the Board of Trade which is of peculiar interest at the present time, as it shows the average number of hours, excluding overtime, worked as a week's work in the principal skilled and unskilled trades of the United Kingdom in the years 1850, 1860, 1870, 1880, and 1890. The Board of Trade sent out 1,448 circulars to employers, and got 962 replies; to trades unions they sent 292, and received 159 replies. The report is confined to a statement of facts, and readers are left to form their own conclusions. One point which is clearly shown, as might have been expected, is that the hours of labour in most of the industries throughout the country have diminished considerably during the last forty years. In one group, however—that of agricultural and dock labourers—the reduction of hours seems to be very slight. Of course, there is some difference of hours in the same industries in different parts of the country. "Dock gatemen" head the list with 105 hours per week in winter, even at the present day. Bakers, except in Birmingham, where, according to their trade union, they still work for 90 hours per week, in some cases show an average of about 9 hours per day. In the building and textile trades the trades unions and the Factory Acts have reduced the average from 10 or more hours thirty or forty years ago to 9 hours or less per day at the present time. Nine hours is also about the average in the principal mechanical trades, such as carpenters, painters, plasterers, coachmakers, engineers, fitters, smiths, &c. Among the sedentary trades there is considerable diversity, and some rather puzzling discrepancies. The hours for miners deserve special attention. There need be little wonder that the Northumberland and Durham miners are not at all anxious for the passing of the Eight Hours Bill, for at present many of them only seem to work from 38 to 44 hours per week. The hours of the surfacemen and firemen are, however, much longer, and vary from 66 to 84 hours per week. In Lancashire, Cheshire, the Midland Counties, Somersetshire, and Yorkshire miners seem to work about 48 hours per week, instead of from 60 to 70 forty years ago. In Wales the average is about 54 hours per week. The returns by employers and trades unions show considerable discrepancies in many cases, while in others the range mentioned is so wide that little information is got from the figures. For instance, a trade union reports that the hours of railway servants generally in Great Britain and Ireland range between 48 and 100 per week. Signalmen's hours usually range from 48 per week to 72, but in some few cases to 84. One of the most minute returns is that given by the Miners' Federation of the details of a collier's day, excluding Durham and Northumberland. The English and Welsh miners are at the coal face from 7½ hours per day, except in the Yorkshire districts, where they work 10½ hours per day. These returns will no doubt be carefully examined and criticised by all who are specially interested in the questions involved, and we commend them to the attention of our readers.

THE SUEZ CANAL.

In the accompanying table is given a return, year by year, of the shipping and tonnage that passed through the Suez Canal from its opening in 1869 to the year 1889 inclusive, a period of over twenty years, which table also shows the progressive increase of the tonnage and of the transit receipts. It will be noted that in 1869 there were 10 vessels, with a net tonnage of 6,576, and the receipts were 54,460fr.; in 1879 the number of vessels transiting the Suez Canal was 1,477, the net tonnage was 2,263,332, and the traffic receipts were 29,686,060fr.; and in 1889 the number of vessels was 3,425, the net tonnage was 6,783,187, and the traffic receipts were 66,167,579fr. In 1890 there were 3,389 ships, the net tonnage was 6,890,014, and the traffic receipts were 67,010,914fr. Notwithstanding this decrease in the number of vessels the total tonnage for 1890 was 6,890,014, as compared with 6,783,338 tons in 1889, or 36 ships less, and 106,676 tons more in 1890.

Year.	No. of Vessels.	Gross Tonnage.	Net Tonnage.	Transit Receipts. Fr.	c.
1869	10	10,557·61	6,576·00	54,460	80
1870	486	654,915·02	436,609·37	5,159,327	22
1871	765	1,142,200·46	761,467·05	8,993,732	87
1872	1,082	1,744,181·32	1,160,743·54	16,407,591	42
1873	1,173	2,085,072·61	1,367,767·82	22,897,319	18
1874	1,264	2,423,672·22	1,631,650·14	24,859,383	00
1875	1,494	2,910,708·45	2,009,981·09	28,886,302	27
1876	1,457	3,072,107·01	2,096,771·61	29,974,998	74
1877	1,663	3,418,949·72	2,355,447·69	32,774,344	22
1878	1,593	3,291,535·38	2,269,678·31	31,098,229	18
1879	1,477	3,236,942·32	2,263,332·19	29,686,060	81
1880	2,026	4,344,519·89	3,057,421·88	39,840,487	64
1881	2,727	5,794,491·19	4,136,779·77	51,274,352	95
1882	3,198	7,122,125·68	5,074,808·88	60,545,882	08
1883	3,307	8,051,307·30	5,775,861·79	65,847,812	16
1884	3,284	8,319,967·36	5,871,500·92	62,378,115	54
1885	3,624	8,985,411·80	6,335,752·98	62,207,439	21
1886	3,100	8,183,313·15	5,767,655·84	56,527,390	58
1887	3,137	8,430,043·20	5,903,024·09	57,862,370	71
1888	3,440	9,437,957·32	6,640,834·44	64,832,273	20
1889	3,425	9,605,745·48	6,783,187·12	66,167,579	14

British vessels transiting the canal in 1890 amounted to 2,522 out of the total number of 3,389, as compared with 2,612 British ships out of a total of 3,425 in 1889, and 2,619 out of a total of 3,440 in 1888. The net tonnage of 2,522 British ships transiting the canal in 1890 was 5,331,533 tons, as compared with a net tonnage of 5,358,072 for 2,612 British vessels in 1889, or a decrease of 90 ships for 1890, and only a decrease in net tonnage of about 26,500, so that the mean net tonnage per ship has increased. The number of French vessels transiting the canal was 171, as compared with 168 in 1889 and 187 in 1888; the net tonnage of these 171 ships was 366,262 tons. After the British, with 2,522 ships, the next in numerical order are Germany, with 275; France, with 171; Holland, with 144; Italy, with 87; Austria, with 55; Norway and Sweden, with 43; and Spain, with 32.

In 1890 the average time of transit was considerably shortened, and only took 24 hours 6 minutes; whereas in 1889 it was 25 hours 50 minutes; in 1888 it was 31 hours 15 minutes; in 1887 as long as 33 hours 58 minutes; and in 1886 not less than 36 hours.

The following table shows the number of ships that navigated the Suez Canal with the electric light, month by month, during the years 1887 to 1890 inclusive, and in this latter year the number amounted to as many as 2,836 with electric light out of a total of 3,389 vessels transiting the canal.

Months.	1887.	1888.	1889.	1890.
January	13	86	207	242
February	12	99	186	232
March	15	110	221	237
April	19	128	240	249
May	19	139	190	245
June	25	116	193	214
July	27	135	216	242
August	35	140	186	209
September	45	140	185	219
October	49	167	208	243
November	63	173	203	228
December	73	178	210	276
Total	395	1,611	2,445	2,836

In the year 1889 the average time for the transit of vessels travelling at night with electric light was 22 hours 30 minutes, or 4 minutes more than the mean time in 1888, and in 1890 reached the short and quick passage of 22 hours 9 minutes.

The following table will show more clearly the progress that has been made in shortening the time, and gives an average of the number of hours taken in the transit of the Suez Canal:—

	1887. H. M.	1888. H. M.	1889. H. M.	1890. H. M.
Average time of transit	33 58	31 15	25 50	24 6
Average time with electric light	—	22 26	22 30	22 9
Shortest time	14 65	14 55	14 45	14 15

THE SPEED TRIALS OF FAST SHIPS.

In connection with the experiments which are being conducted under the auspices of the Institution of Mechanical Engineers, we have recommended that the Committee should issue regulations for conducting trial trips, as at present the results which are published cannot be depended on, the methods of observation and experiment being so varied. This is true as regards coal consumption, and also speed. On the latter we find a paper in the Journal of the American Society of Naval Engineers by Messrs. Norton & McFarlane, assistant engineers in the United States Navy, in which four methods of measuring the speed of a vessel upon a trial trip are discussed. These are—(1) By readings of patent logs; (2) by successive runs in opposite directions over a measured distance; (3) by a continuous run at sea, the speed being based on the number of revolutions of the propeller found necessary to give a knot in smooth water; (4) by a continuous run at sea past a series of buoys, or stations on shore.

Although the first has the great advantage of simplicity, it is found to be entirely untrustworthy, and is therefore condemned, and the authors back up their condemnation by evidence which cannot be disputed. They recommend for the second method of measurement a course of 1 knot, instead of one of 10 knots, which has been proposed, as in the latter case the intervals would be so long that the change in velocity of the tide would introduce a very appreciable error. When the third method is chosen, it is necessary to determine the number of revolutions per minute and per mile for various speeds in smooth water, by runs in opposite directions over a measured knot. Large vessels should have a depth of water of not less than 19 fathoms. Several sets of runs should be made at different speeds; at least four, and, if possible, six runs at each speed. The revolutions should be counted with the greatest accuracy, and curves plotted on a large scale, showing revolutions per minute and per mile, with the speeds for abscissæ, so that speeds to the hundredth of a knot may be determined. On the continuous trial, which should be of four hours' duration, readings from two counters attached to each shaft should be taken every ten minutes. The total number of revolutions made in the four hours being determined, the average revolutions per minute can be obtained, and from them

Digitized by Google

the number per mile and the speed of the vessel. The fourth method is troublesome and expensive, and involves a large number of observations, so that on the whole the authors favour the third method. They think that by using a chronograph which will read accurately to the tenth of a second, and revolution counters of which the error will be less than one revolution, sufficient accuracy may be obtained.

Letters to the Editor.

THE FRICTION OF BEARINGS.

To the Editor of "Industries."

Sir,—I have to thank you for the honour you have done me in reproducing the remarks which I made at the meeting of the Institution of Mechanical Engineers on the 19th inst., but I regret that, by the omission of the reference which I made to the results of certain of the experiments which were then under discussion, the purpose of the suggestion which I submitted for the consideration of the meeting is lost, and the introduction of the viscosities of sperm oil and of lard oil is rendered meaningless and superfluous.

What I had in my mind and desired to bring before the meeting was the fact that increase in temperature, whether caused by augmentation of pressure or of speed, is accompanied by a reduction in the coefficient of friction.

It has been demonstrated by the elaborate experiments of the Eastern Railway Company of France—

(*a*) That, with constant speed and uniform conditions of cooling the journal, *augmentation of pressure* produces increase in temperature and diminution of the coefficient of friction.

(*b*) That, with constant pressure and uniform conditions of cooling the journal, *increase of speed* causes an increase in temperature and corresponding diminution of the coefficient of friction.

(*c*) That, when equality of temperature is maintained, the coefficient of friction increases with the speed.

These deductions appear to be wholly consistent, as far as it is possible to compare them, with the results of the extensive series of experiments which have been planned and carried out under the auspices of the Institution of Mechanical Engineers, from which, if I correctly apprehend them, the following additional deduction is to be made—viz., that, temperature and speed being constant, the coefficient of friction diminishes with increase of pressure.

These rules are not wholly unrestricted in their application—*i.e.*, the diminution of the coefficient of friction which results from increase in pressure, speed, and temperature is only observed within certain limits—but I understand that these limits are such as engineers accept as being imposed upon them by other considerations and as being practically coextensive with their requirements.

I may add that the results of both of these series of experiments confirm in the fullest manner the conclusions which I had arrived at from various series of frictional and other experiments in which I have taken part at different times.

As, therefore, it appears to be established that temperature increases and the coefficient of friction diminishes with augmentation of pressure and (or) speed, I infer that this diminution of coefficient of friction is due to reduction in the viscosity of the lubricant accompanying evolution of heat. Hence I referred to lard oil and to sperm oil in order to suggest that, as lard oil (Table IX. of 1st Report) at a speed of 100 revolutions per minute, and with a load of 100lb. per square inch, gave a coefficient of friction = 0·0024 at 120° Fahr., while sperm oil, under the same conditions of speed and pressure (Table IV. of 1st Report), gave a coefficient of friction = 0·0025 at 90° Fahr., it is probable that the viscosity of lard oil at 120 Fahr. and of sperm oil at 90° Fahr. are almost identical.

I think that it used to be held that the temperature of a bearing was an indication of the power required to drive it, and of the anti-frictional value of the oil or other material employed to lubricate it, and not a few testing machines for lubricants have been designed and constructed on this theory, but, if the facts now stated are as trustworthy as they appear to be consistent, it is evident that all readings from such machines must be taken subject to several very important qualifications, and it may be asked whether, within moderate and safe limits, it is not better and more economical to run machinery at a temperature somewhat over, rather than expend energy in attempting to keep bearings at or near, normal atmospheric temperatures.

If any practical guidance in the selection of lubricants is to be gained from these experiments it is, I think, unmistakably and unquestionably that, instead of choosing thick oils as likely, on account of their "body," to stick to the journals, preference ought to be given to the thinnest oils which may be used consistently with the weight of the machinery, bearing also in mind the fact that a thin oil will find its way where a thick oil will fail to do so. In the case of heavy planing machines, thin oil will leave a film when and where a thick oil would be entirely scraped or rubbed off.

I regret that this doctrine is not generally accepted by engineers, to the majority of whom "great body" in an oil seems to be the first and the final desideratum. It may be that the use of a thinner oil calls for more care in the selection and adjustment of the apparatus by which the lubricant is to be applied, and for closer attention on the part of the man in charge to see that bearings are regularly and properly lubricated, while thicker oils may, perhaps, dispense with such close attention, but I am strongly of opinion that "hot bearings," both in land and in marine engines, are more frequently due to excess rather than to deficiency of "body," and are to be got rid of by the intelligent and careful use of oils of moderate "body" rather than by the use of the oils of excessive viscosity which have been introduced within the last few years.

Yours, &c.,
J. Veitch Wilson.

Belmont Works, Battersea, S.W.,
28th March, 1891.

MR. KAPP'S CANTOR LECTURES.

To the Editor of "Industries."

Sir,—From the report on Mr. Kapp's lecture in your issue of March 6th it appears that Mr. Kapp has stated that "there is another method of alternate current transmission, known as the three-phase current system."

A system, which may be called so, has been described by me in patents of 1888. In this system the generator has three circuits with a common joint, and the three free ends are connected to the terminals of a similarly constructed motor. This system has been used and thoroughly tested by me in many modifications. I do not agree with Mr. Kapp that its plant efficiency (if Mr. Kapp means this system) is "much greater than with the Tesla system." Its advantage is that the e.m.f. on all circuits is equal, but it has many disadvantages as compared with the two-circuit three-wire system under ordinary conditions. As it is, however, desirable to use one or the other plan, I have pointed out the advantage of making a motor with a number of poles which is a multiple of two and three.

Mr. Kapp seems to make a distinction between the "Ferraris two-wire system," the "Tesla three-wire system," and the "three-phase current system." I do not need to point out that my invention is not a two-wire or three-wire system, nor a two-phase or three-phase system. What my invention is Mr. Kapp may see if he will take the trouble to peruse my patents.

I infer from other papers that Mr. Kapp has stated that I have "worked in the line indicated by Professor Ferraris." I may call his attention to the fact that the date of filing of my application for the American patent anticipates the Ferraris publication in Italy by something like six months; I therefore cannot have worked in the direction indicated by Professor Ferraris.

The statements of Mr. Kapp would appear to imply that I am an imitator. I need not say that I am not an imitator. My aim is to produce original work or none at all.

Yours, &c.,
Nikola Tesla.

New York, 17th March, 1891.

THE SHIPS AND ENGINES OF THE NAVY.

To the Editor of "Industries."

Sir,—The Parliamentary Return on the "Engines in the Navy," to which you alluded in your last issue, shows that the Admiralty are beginning to break through the policy of secrecy which has characterised almost all their transactions. I hope they will be induced or compelled to go further. In connection with the science of shipbuilding, there is a great mass of information regarding experiments carried out by the late Mr. Froude, by his son, and others, which should be made available to the whole of the profession. There may be some points on which public policy makes it necessary to put the seal of secrecy, but things of purely scientific interest, which are being worked out by a public department, should be public property. Moreover, I think the time of the officers in Her Majesty's Navy should be utilised to a much greater extent than it is at present, by asking them to collect information and make experiments regarding their ships and engines. Life on board a man of war is not of a very intellectual nature, and such employment would add much to the enjoyment of life, and to the information of the profession and of the public. They might make observations regarding speed under varying conditions, stability, rolling, resistance, &c., of ships, and the efficiency of engines both as regards the steam, the mechanism, and the boilers. A little has been done regarding the latter by the Institution of Mechanical Engineers, but a great deal still requires to be done, and there are no reasons why the services of public officers should not be utilised to collect information which would be of the greatest advantage.

Yours, &c,
Marine Engineer.

Glasgow, 28th March, 1891.

THE INSTITUTION OF NAVAL ARCHITECTS.

To the Editor of "Industries."

Sir,—The recent meeting of the Institution of Naval Architects was very successful, both as regards the quality of the papers read and the attendance of members, but still it was felt that some of the criticisms which have been passed on the methods of conducting the work of the Institution were more than ever required. Although I have said the papers were of good average quality, and some of them of a very high standard, still I am of opinion that the programme might have been better, certainly more representative of the various departments of naval architecture and marine engineering, and of the practice in different parts of the country. It certainly looks strange that not a single paper came from the Clyde district. I have no doubt it will be said that that was the fault of the Clyde engineers and shipbuilders, and to a very considerable extent that is true, but the feeling seems to be that the Institution is essentially a London institution, and that its management and the preparation of papers for it may largely be left to the members in and around London.

The greatest objection to the present system of management is that too much is attempted in a short time, and for the rest of the year the Institution is practically defunct. It is rather difficult to justify the maintenance of a staff for three days' public work, for no one can doubt but that the editorial work could be done in the leisure time of a competent man. It has been hinted more than once that if some inquisitive M.P. examined the accounts, and discovered that the Admiralty made a grant of £250 a year, he might ask some rather difficult questions as to the return the country got for this money, and, in fact, might dispute the necessity for any such payment to an Institution having so many rich members.

I am glad to learn that the Council propose in future to hold two meetings every year. I would suggest that they go even further, and hold three—one in London, one in Newcastle and Liverpool in alternate years, and one in Glasgow. This arrangement would include the chief shipbuilding districts, and would arouse a local interest in the affairs of the Institution. The meetings need not extend over more than two days at each place, and everything should be done in the simplest and least expensive manner possible. I believe that hitherto the provincial meetings have always involved far too great an expenditure of money, not on the part of the Institution, but of the local members and their friends. A large guarantee fund has always been got up, and rather expensive entertainments provided, all of which, in my opinion, are unnecessary. The Institution would have no difficulty in obtaining the use of a hall free of charge, and there are no reasons why members should not pay for any dinners, luncheons, or other entertainments they attend. These have hitherto been far too important parts of the programme; in fact, so much so that the reading of papers has sometimes seemed a subsidiary function.

I think, moreover, that the value of the Transactions would be very much improved if the plan of the Institution of Civil Engineers were adopted, and correspondence invited from well-known authorities on the subjects of the different papers, and if digests of papers which have been read before other institutions were incorporated. In looking over my set of the Transactions of the Institution of Naval Architects, I have been struck with the fact that they have not developed from year to year, either as regards quantity or quality, in the way that the Transactions of other institutions have done. I am sure that if the suggestions I have made were adopted, we would soon soon see a very great improvement.

Yours, &c.,
M.I.N.A.

Glasgow, 28th March, 1891.

THE CHEMICAL SOCIETY'S ANNUAL GENERAL MEETING.

To the Editor of "Industries."

Sir,—In contrast to the amity and fertility that distinguished its recent jubilee meeting, the business gathering of the Chemical Society, which took place on the 25th ult., was characterised by the clash of opposing parties with fiercest war of words. Quite in accordance with recognised usage was the presidential address, handsomely admitting the need of some reform being begun, cautiously deprecating any alteration of a decisive kind, and amiably endeavouring to pour oil on very troubled spirits

Starting with a proposition of Euclidian sententiousness, that because most good chemists are "Fellows," therefore it has been erroneously supposed that most Fellows are good chemists, Dr. Russell reminded his hearers that the agitation for importing greater stringency into the regulations for the admission of Fellows, which is now a burning question, was in no way new. In 1867 a similar movement had existed; the propositions put forward were referred to a committee, which, in the manner of committees, recommended some kind of verbal compromise, and then had been conveniently stifled. Then, as now, two sets of views were current. One was held by those who considered the Fellowship in some sort a qualification implying professional proficiency, and therefore wished to exclude the incompetent. The other, by a party of diametrically opposite views, who looked upon the Chemical Society in the light of a chemical club open to all socially unobjectionable, and having a real interest in chemistry, whether as amateurs or professionally.

The growing need of some body to hall-mark professional chemists, which was at the root of this agitation, had led to the formation of the Institute of Chemistry in 1877, to act mainly as a qualifying body. Although this Society, as you have recently shown, now exists, yet its existence did not remove the onus of exercising some discretion by the Chemical Society "as to who (*sic*) we may desire to be admitted." Inasmuch as a certain distinction attached to the letters "F.C.S." it was necessary "to exclude unsuitable persons," an aim which had hitherto been attended "with imperfect sucess." In spite of this, however, the Chemical Society had grown both in numbers and standing during the last fourteen years, and on the adoption of the alterations in the procedure for the election of Fellows, which would be submitted to the meeting, all but a few objectionable persons would be excluded, and these might be left to work out their own destruction, while "any Fellow acting dishonourable (*sic*) or wrongly' could be adequately dealt with.

This, Sir, was the penultimate clause of an address which, if not remarkable for grammatical precision or elegance of diction, was a straightforward attempt to mitigate, without altogether nullifying, the effects that would have been produced by the adoption of the proposals of the more rabid reformers.

The most useful and interesting announcement made throughout the evening was, however, reserved for the last. Those unprincipled persons who were accustomed to assume and trade upon titles falsely indicating that they belonged to such bodies as the Chemical Society would, it was hoped, soon be summarily dealt with. A Bill had been drafted jointly by the Royal Society, the Royal Astronomical Society, the Chemical Society, the Society of Antiquaries, the Geological Society, and the Linnean Society, making it penal for unauthorised persons to assume the titles respectively conferred by them.

After the President had thanked the officers of the Society for their co-operation, in the execution of which function it was refreshing to see one of the Secretaries following the example of the immortal Mr. Jingle, and vigorously applauding himself, the usual laudatory motions re the address were made, Mr. Carteighe particularly distinguishing himself by his flowery imagery, alleging that the "address breathed a spirit, gentlemen, which is I think a sound spirit," but opportunity of judgment in this particular is, I am sorry to say, wanting, no samples being to hand.

Facts and figures from Professor Thorpe, the Treasurer, gave satisfaction to the statistically disposed, and led Dr. Stevenson to complain that too little was spent on the library, a complaint which all who use it will endorse. Another useful suggestion was made by Professor Ramsay, who wanted some assistance and apparatus to be available for the use of Fellows about to read papers to be illustrated by experiments before the Society. The election of new officers and members of Council went off without a hitch, Mr. Crum Brown being next year's President.

So far it had been fairly smooth sailing, but now there came that expectant hush premonitory of conflict. Goaded by the

Digitized by Google

persistency of the reforming "movement," the Council had prepared some proposed alterations in the bye-laws relating to the election of Fellows. Many exhausted members having retired for refreshment, Mr. C. E. Cassal, undoubtedly the participator in the "movement" having the greatest weight, proposed ringing the bell used on such occasions and summoning the laggards to the fray. This done, Mr. Lloyd, one of the secretaries of the "movement," arose, and with appalling prolixity inquired whether a motion could be brought forward at the meeting of which notice had not been given. The President ruled that it could not, to the consternation of the leaders of the "movement." This brought Mr. Lloyd once more on his legs and gave him some reason for evolving a stream of words more or less limpid.

Great interest and curiosity were displayed by the meeting as to the number of persons composing the "committee" responsible for the "movement," but Mr. Lloyd declined to gratify this laudable desire, asserting, with Delphic obscurity, that "number's nothing," leaving it to be divined whether he wished to indicate his scorn for mere multitude, or to assert the non-existence of the committee itself. He then wished to move that the whole of the amendments proposed by the Council should be postponed to the next annual meeting, but this was ruled out of order by the Chairman. The heavy artillery of the "movement." in the shape of Mr. Cassal, then opened fire, and inquired on what authority that ruling was made.

When at length the momentous question as to the acceptance of the Council's proposed amendments came to the vote, the opposition "movement" mustered as many as five hands! Thus ended a storm in a teacup. Who shall say after all that passed at this meeting that chemists are not capable of self-government?

Yours, &c.,
CHEMIST.

London, 28th March, 1891.

THE USE AND ABUSE OF MATHEMATICS.

To the Editor of "Industries."

SIR,—As you have recently published a very interesting correspondence on the question, "Is the Study of Thermodynamics of Use to Engineers?" I am induced to send you some ideas upon a subject of kindred importance.

There always has been, and probably always will be, a sort of feud between the so-called theorist and the practical man. The conventional theorist is not really a theorist at all, he is assumed to have only an imperfect and one-sided knowledge of his subject; similarly the conventional practical man is anything but a practical man, as he is supposed to have nothing more than a rule-of-thumb knowledge, a kind of knowledge which defies analysis. The true theorist and practical man should be one and the same individual. He will have studied the thermodynamics of his steam or gas engine, and he will also know what kind of cylinder oil to use, and the price of it.

I do not wish to discuss the relative merits of theory and practice in this narrow sense, but only to say a little about the use of mathematics. There is often an outcry against mathematics, and the engineer who says he does not believe in them is quite common. I remember one who stated in print that he did not believe in heavy integrals, whatever that may mean. On the other hand, the mathematician declares that mathematics is the essence of sense, and the people who revile mathematics are those who do not know any. There is here no common ground, and such discussions are futile; but though no one can deny that considerable mathematical knowledge is absolutely necessary to an engineer, there does seem to be much reason in the outcry so often made against the so-called mathematicians. In the first place, mathematics is not highly developed reasoning; such a definition is too large. The higher branches of reasoning are inductive; mathematics is simply concentrated deductive reasoning about quantity.

There is a vulgar quality in the human mind which makes us reverence anything we do not understand. This is shown most strongly in savages, but the same weakness exists in civilised men. Many a reputatation in literature, art, and music is due wholly to the great man's knowledge of this little failing. If a man who knows a little chemistry comes across a paper on a chemical subject which he cannot understand he feels that he merely has to look it up to know all about it. But if he comes across a mathematical paper beyond his reach, he finds symbols and characters which convey no meaning to him, and he falls prostrate and worships. This being so, it is scarcely in human nature for a mathematical man not to flourish his mathematical knowledge in the face of the world at every opportunity. If people realised that mathematics is not really a very high intellectual exercise, but requires little more than close attention and concentration of thought, it might be better.

The admission of women to the Cambridge examinations is calculated to do great good. It will not have the effect of opening the eyes of men to any unsuspected intellect in women; it will merely let them see that the passing of University examinations is not, after all, such a very difficult matter, and that even higher mathematics is not a study requiring any transcendent abilities; that, in fact, many an ordinary person might have been Senior Wrangler if he could have had a few years free from care, work, or anxiety, with the stimulus of others around him, and tutors to help him to do nothing whatever but read mathematics in a systematic and regular way.

The chief real complaint against mathematicians is that they are apt to over-rate the value of mathematical work, and to forget that they are only employing deductive reasoning. Nothing is commoner than to find a simple law assumed, and then followed by pages of calculations which would be useful if the assumed law were true, but are really valueless. This vice is especially common in electrical literature. When electrical engineering began, few engineers were well enough up in electricity to be independent of the advice and fuller knowledge of the various science teachers. The result is that electrical engineering has ever since remained a sort of 'Tom Tiddler's ground," and it will be long before the profession settles down into a state corresponding with other branches of engineering.

The feud between the practical man and theorist, in the narrow and incorrect sense of the terms, has therefore raged very bitterly in that profession. The study of dynamos was retarded for years while pages and pages were written showing how dynamos would behave if the pressure were this function or that function of the excitation. Each equation contained some coefficients, so that each writer could make his law fit roughly. To this day reams and reams of calculations about transformers are published in which harmonic functions are assumed.

Not long ago a scientific paper published an account of a chemical balance which was rendered dead-beat by two air dash-pots. This was a very good idea. The description was followed by a whole series of calculations, showing the "damping" in terms of the dimensions of the dash-pots, and assuming certain laws of air friction to hold good. But this is playing at science. Anyone would naturally make the piston fit as closely as possible without touching, and, if the balance was then too sluggish, would make it looser.

Cambridge sets the fashion in mathematics. No one but a Cambridge man is supposed to be capable of anything in mathematics. A few Dublin men have had a glimmering of knowledge, but an Oxford graduate is in outer darkness, and an unfortunate who has read by himself and never been to any University at all is doomed to eternal ignorance. In spite of this we hope that someone may write a book on practical mathematics which contains just those subjects which are necessary for engineers, and nothing more. We do not mean a book of simplified explanations. They are delusive. Such explanations as Clifford's are very striking to those who understand the matter beforehand, but probably no one ever learnt anything for the first time from them. For practical work graphical methods should be much more developed than they are. The Cambridge man looks upon a graphical solution of a problem as a kind of foul play, and would as soon think of solving an equation by trial, or by omission of an unimportant term, or in any other reasonable way.

Perhaps the chief cause of the differences between "college men" and commercial engineers lies in the former's ignorance of actual requirements and cost of making. Recently a ploughing engine was severely criticised on account of its absurd proportions. Its shaft was large enough, said the writer, to transmit some hundreds of horse-power; and it was assumed that the makers did not know the laws of the torsion of shafts. The critic really did not know the requirements of a steam plough. Such an engine must not only plough, but it must stand the roughest usage in steeplechasing across country. It is no easy matter to calculate the proportions of an engine that will damage nothing but a bridge in falling through it.

Take, for example, a marine engine. Theoretically it is all to be carefully designed on the principle of Wendell Holmes' "Deacon's Masterpiece." In practice nothing of the sort can be done. The head draughtsman looks out the drawings of a former engine of about the same size. He has them traced with a few of the dimensions altered. He works in as many existing patterns as possible, and the details are all designed by eye, keeping as nearly as possible to the dimensions of some engine already made. No other course would pay.

What is really needed is a combination of theoretical and practical knowledge. It is very doubtful if our training is best for engineers. A boy leaves school early and serves an apprenticeship which is entirely practical. Before there can be effective combination between the so-called theorist and practical man, the mathematician must realise that he knows little or nothing about engineering, but that what he does know would be useful in the hands of commercial engineers; and engineers must understand that though the mathematician, or theorist, or college man could not design an engine that would work, some of his knowledge would be very useful. In fact, a little more modesty on the part of the "college man" would be of the greatest advantage to all.

If any of your readers have "something on their mind" similar to the above I hope you will allow them to disburden themselves.

Yours, &c,
ELECTRICIAN.

Leeds, 28th March, 1891.

NOTES ON PATENT LAW.

I.

THE number is legion of treatises on the subject of Patent Law, which have even within the past few months been issued from the press in the form either of original works or new editions. But these are almost without exception intended as text-books for lawyers, and aim at dealing in its entirety with this somewhat large branch of law. They are, consequently, both too large and fragmentary to be of any great service to the general reader. They are voluminous books, which only a student of the subject can afford the time to read systematically, and the authors confine themselves so strictly in their utterances to the language of decided cases that it is generally very difficult to obtain from them any general proposition that covers a particular point of difficulty. It thus happens that, in spite of their excellence as manuals, they are by no means serviceable as books of reference to the general reader, and it is believed that the series of articles of which this is the first will supply a felt want in the way of exhibiting, stripped of technicalities, so far as that is possible, the main outlines of the British Patent Law in those of its aspects which are of distinctively general interest.

There are two classes of persons, excluding the patent lawyers, who are specially interested in patent law—they are (1) inventors and (2) investors in patents. The inventor and the investor are for many purposes antagonists, and every one has heard some touching story of a clever but simple-minded inventor robbed of the fruits of his ingenuity by the wiles of a crafty investor, who has bought the inventor's right for some trifling or illusory consideration, and exploited them to his own immense advantage, without so much as entertaining a passing thought of making the original source of his profits a sharer in their advantages. But although such cases of hardship have undoubtedly occurred in the past, and will occur again in the future, they will affect only a very small part of what we have to put forward. The more common, though much less generally recognised case, is that the inventor and the investor co-operate loyally and to their mutual advantage; and, again, cases are frequent where the inventor is able, without any external assistance, to put his own invention on the market, and thus to combine the two characters in himself. We shall first, then, consider those points which affect them both in the same way—in respect, that is, of their common interest. The consideration of working agreements between co-adventurers will form a separate topic for after consideration.

This plan leads naturally to the discussion in the first place of the patentee's rights, since they lie at the foundation of any advantage which can be secured either by himself or by those who share in his undertaking. These rights are derived from two sources—certain Acts of Parliament and the Royal Grant; and for their full definition both must be consulted. The principal Act under which all existing patents have been created is, curiously enough, an Act directed *against* monopolies, and primarily intended for their suppression. The right of granting trading monopolies claimed by the Tudor sovereigns and by James I. was so enormous and oppressive that Parliament put in the very forefront of its demand for reforms when its dispute with the House of Stuart waxed vehement a demand that they should be abolished. Hence resulted, after a great deal of royal evasion, the celebrated Statute of Monopolies, in the year 1623, by which it is declared that "all monopolies, and all commissions, grants, licenses, charters, and letters patents heretofore made or granted or hereafter to be made or granted to any person or persons bodies politic or corporate whatsoever of or for the sole buying selling making working or using of anything within this Realm or the Dominion of Wales . . . . and all proclamations, inhibitions, restraints, warrants of assistance, and all other matters and things whatsoever any way tending to the instituting, erecting, strengthening, furthering, or countenancing of the same or any of them, are altogether contrary to the laws of this Realm and so are and shall be utterly void and of none effect, and in no wise to be put in use or execution." From this very sweeping denunciation an exception was allowed, which is provided for in the following terms:—"Provided also and be it declared and enacted, that any declaration before mentioned shall not extend to any letters patents and grants of privilege for the term of fourteen years or under hereafter to be made of the sole working or making of any manner of new manufactures within this Realm to the true and first inventor and inventors of such manufactures which others at the time of making such letters patents and grants shall not use, so as also they be not contrary to the law, nor mischievous to the State by raising prices of commodities at home or hurt of trade or generally inconvenient."

Upon this exception has been engrafted the entire patent law, for although it must be admitted that subsequent legislation, and still more the modifications introduced by the judges in their interpretation of the clause, have caused its effect to vary from time to time, in the end, and in spite of the jealousy of monopoly which breathes through the whole Statute, and has at various times found expression from the judicial bench, inventors have received a very large measure of privilege. Thus the grantee of a patent may, while the grant lasts, attack the maker, vendor, or user of his patented invention, and if he makes good his claim, may enforce his right by requiring that the objectionable "manufacture" should be either delivered up to himself or destroyed, besides recovering pecuniary damages against the person who is shown to have committed the infringement of his rights. But this is not the whole measure of a patentee's rights. The letters patent under which he acquires them confer on him and on his personal representative or assignee the power of making use of his invention "by himself, his agents, or licensees." Thus he is able, not only to monopolise the use of his invention in his own hands, but to become a source of similar privilege in other persons, so that he can not only make over his rights by a sale of the patent itself, but, if he so prefer, he can, while retaining the paramount right in his own hands, concede to others the subordinate right of manufacturing under his licence, and on any terms as to the payment of royalties or sharing of profits, to which he and they can agree. It is this power of sharing his privileges which gives to the position of a patentee its great commercial value and advantage, and for our present purposes it is, therefore, all-important. Before passing to that point, however, we must pause to consider the statutory limits of the patentee's rights as above defined, a subject which will afford material for our next article.

THE "HARLOW" SIGHT-FEED LUBRICATOR.

The accompanying illustrations represent in Fig. 1 a general view of the above lubricator, and in Fig. 2 a sectional elevation of the oil cup. The lubricator is made by Messrs. Green & Boulding, of 21, Featherstone Street, City Road, London. The apparatus is automatic in action, and has a positive feed. As will be seen from the sectional view, the oil is fed from the cup by means of a plunger actuated by means of a rack C in which gears a pinion B caused to revolve by means of a lever and rod connected to any suitable moving part of the engine. The feed can be regulated by means of the wheel valve A, and is further controlled by means of a spring valve D. The lubricant, previous to passing out of the cup, is strained through a strainer F, so as to prevent any foreign material which may be suspended in it from passing to the bearing. The whole is nicely finished in brass or nickel, and the wearing parts are reduced as far as practicable.

THE INSTITUTION OF NAVAL ARCHITECTS.

(*Continued from page* 293.)

The first paper, on Friday, the 20th ult., was read by the Secretary. It was by M. J. Barba, late engineer in the French Navy, and now chief engineer of the Creusot Works, on

Recent Improvements in Armour Plates for Ships.

A historical sketch of the manufacture and trials of armour plates was followed by a discussion of the formulæ for penetration. The effects produced by impact on the projectiles, and the secondary effects of impact upon the plates, were dealt with, and the author concluded with a statement which may be summarised as follows:—The Schneider plates have kept out the projectiles better than any others, in the opinion of the various Governments. Armour should stop any projectiles and limit the damage to the hull of the ship. Cracks do not exercise any influence on the perforation. A laminated structure, assisted by the introduction of nickel, will reduce cracking, but cracking must always appear to a certain extent. In ships, where it is unlikely that two projectiles will strike in the same place, the first thing to do is to keep out the first projectile. For this purpose the metal must be hard throughout its whole mass. Nickel seems to increase notably the degree of hardening, especially with large masses. With a similar composition to all-steel plates, the Schneider plate allows greater hardness, and the easier breaking of chrome steel projectiles when they are not of the best quality; perhaps also of the best ones when they are of large diameter. From this fact the penetration will be less. A laminated structure and the diminution of cracks resulting from it may be an advantage, but it is not to be put on an equal footing with the former. Numerous points of attachment are necessary.

A long discussion followed the reading of M. Barba's paper, which was extensively criticised by several of our largest manufacturers of armour and others.

Mr. Alexander Wilson, of Workington, said he did not see much to discuss in the paper, as so much was omitted from it. There was but little in it to prove that solid steel was better than compound armour. For his own part, he still made a great deal of the latter, and thought it was much the best. Compound armour resists the old cast-iron shells, and also resists solid forged steel shells as a rule, but the solid steel is penetrated. Explosive shells are extremely dangerous if they penetrate, and they are best kept out by compound armour. When speaking of lamination the author seemed, in fact, to prove that compound armour was the best. His firm had made many experiments with a view of reducing penetration, and at the latest Ushant trials compound armour had behaved admirably.

Mr. Ellis regretted that his father was not present to represent Messrs. John Brown & Co., of Sheffield. Several points in the paper did not seem to have sound foundation. Lamination in compound plates was a necessity of manufacture, but it was not easy to see what caused it in solid steel armour. The author candidly admitted that the resistance of solid steel to common shell was less, and this was a vital point, as, for every forged steel shell that will strike the armour, there will be from fifty to a hundred common shell. The bulk of the shot must be kept out, and this gave a superiority to compound armour. In this kind of armour the hard face will give a much greater resistance to obliquely striking shots, of which there will be a large number in actual warfare. His firm were now making plates up to 32 tons in weight.

THE "HARLOW" SIGHT-FEED LUBRICATOR.

Constructed by Messrs. Green & Boulding, Engineers, London.

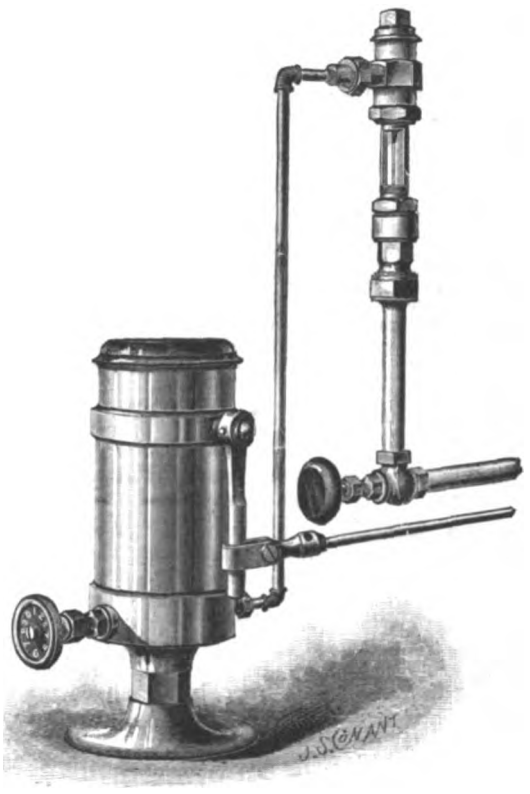

Fig. 1.

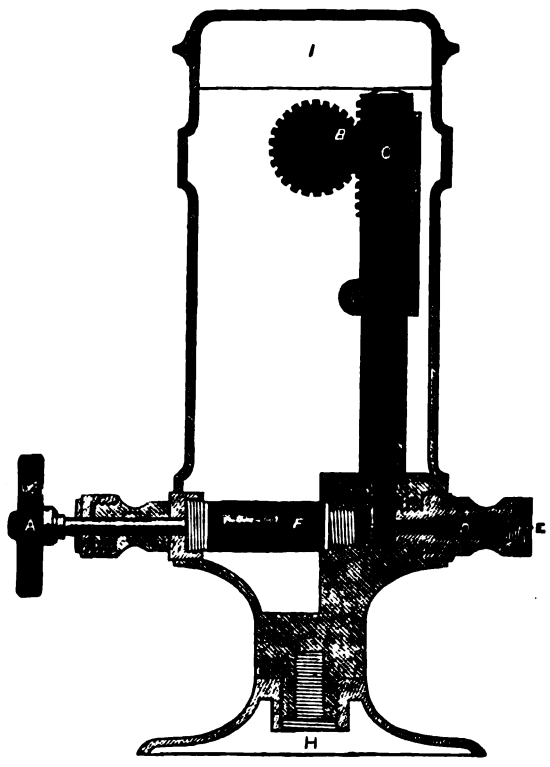

Fig. 2.

Mr. T. E. Vickers thought that it would have been better if the paper had been more scientific, and less of a trade puff. The statement with regard to armour trials in Russia was not borne out by the Russian official report. He quite agreed that the question was one of toughness and resistance. As a manufacturer, he tried to get the maximum of ductility and hardness together, so as to follow a medium line. At Annapolis the nickel-steel was tough, and was penetrated, but did not crack, so that it was considered the best; but the Russians had not taken that opinion. He could not understand how nickel or any metal could cause a laminated structure in solid steel plates. In large plates there is often a fracture parallel to the face, but it could not be supposed that this was caused by lamination existing prior to the plate being struck by the projectile. There must necessarily be toughness to prevent cracking.

Mr. J. F. Hall, of Messrs. Jessop & Sons, and of the English Nickel-Steel Syndicate, stated that one of his nickel-steel plates was tried before the Annapolis tests. He referred to Mr. James Riley's paper, read before the Iron and Steel Institute in 1889, as containing much valuable information. The difficulties with the nickel supply were mentioned by the speaker, who also stated that a small works for the production of ferro-nickel was being carried on, and that nickel-steel plates were being manufactured in this country.

Mr. Vickers (the brother of the manufacturer) said he was present in Russia at the time of the St. Petersburg trials, and so was able to give a full account of them. There were five shots fired at each plate, two shots of the softer metal and three of harder steel. The first two shots stuck in the compound plate, whilst the others went right through it. The Schneider plate cracked very badly. The Russian compound plate was also pierced. The Vickers solid steel plate kept out every shell; most of them stuck in, but none went right through. Pieces were broken from the back, but the face remained good. If the toughness was to be considered the best feature exhibited at Annapolis, the same should be done in the Russian trials.

Captain Tresidder had not heard that the first two shells fired at each plate were too soft. These two shots were fired with a velocity of 1,900ft. per second, and the three last shots with a velocity of about 2,100ft. per second. This velocity was excessive, and would never be attained in war, besides which the shots always were fired to strike the plates normally.

Mr. Beardmore, of Glasgow, said he was learning by experience how to make armour. His first plate was too hard, his next too soft, but the medium was the point to aim for.

Sir Nathaniel Barnaby thought that the paper was most disappointing, as he had hoped for elucidation of principles instead of a display of feeling. Schneider was the originator of hard armour, and that caused the use of the hardest forged and expensive projectiles. It was difficult to ascertain what the navy wanted, whether cracking was to be absolutely avoided or not. Was it to be allowed by the use of numerous bolts on the same principle that Whitworth proposed a large number of small plates, each with its own bolts. There appeared to have been some discussion with Messrs. Schneider & Co. as to the terms on which they should supply us with trial plates.

Mr. Biles thought that the plates should not be tested before they were sent for trial, or an unfair sample was likely to be put up. He would like to see some good summaries of the results of trials.

Mr. W. H. White wished to publicly thank steel manufacturers for the confidence they reposed in him. In 1886, the Admiralty determined on a series of trials supplementary to those of 1877, to determine the relative merits of compound and other armour. The plates were to be 8ft. by 6ft., and 10½in. thick. Many firms, including two in Sheffield, who had been devoted to compound armour, sent in samples of solid steel plates which were compared with compound plates as a standard. The results were not published, but each firm was informed how its own plate had behaved, so that improvements might be made. At the present time steel is being largely used for thin armour, and an order for belt armour of solid steel had been given to Messrs. Vickers. The speaker had seen many plates tried, and trials are constantly being made, but it was perfectly impossible to give any hard-and-fast standard, as both cracks and perforation must be taken into account. He wished to remind Mr. Biles that the preliminary tests were chemical and mechanical, and that inspectors were always present when the plates were made. A very important point with regard to cracking was the difference between armour for land defence and armour for ships. The former was likely to be struck several times in the same place, and so must resist cracking to a greater degree. With regard to nickel-steel, the Admiralty had not been idle. They began to look into the matter some two years ago, and they had tested a 4in. plate as early as April last year. Since then many samples of this material had been received and tested, and had showed a very great advance over the first plate obtained. He hoped

Digitized by Google

that he had shown that there were very slight grounds for the reproaches showered on them by the newspapers for their supposed backwardness. He stated that Whitworth's system of small armour plates was untenable, as they could not determine the number of points of attachment satisfactorily. The supports for the plates must be strong. The whole question was simply a battle of armour *versus* projectiles; first one is improved, then the other. The latest development in projectiles was the use of hard shells containing high explosives. The armour must have a hard face to keep them outside. Again, the amount of armour was most important; a vessel might be disabled without the armour being once struck.

The President regretted that M. Barba was not present to answer the objections taken to his paper. He thought that the frank and important statement from the Admiralty would remove much misapprehension. One thing was to be clearly seen, and that was that they must have the best material, whatever the expense might be.

The next paper read was by Mr. Thomas Phillips, and was

On the Alterations in the Form of Steel Vessels Due to Different Conditions of Loading.

The author gave the results of a series of experiments that had been carried out during the past three years, and which, in the first instance, were undertaken at the request of the Committee of Lloyd's Register, who had instructed him to carefully note any changes that might take place in the sheer of a certain steel screw steamer of the well-decked type during the process of loading; it having been reported to the Committee that a sister vessel in every respect, and built in the same yard, had sagged when fully laden to an extent whereby the guaranteed deadweight carrying capacity on a fixed draught was not realised. As the subject of the strength of vessels to resist vertical deflections had not been treated in any paper, except from a purely theoretical consideration of the question, he trusted the information obtained by experimental researches would prove of interest. It has been customary, in the case of her Majesty's ships, to take sights of their sheers before and after launching. In iron vessels the break in the sheer was practically nil, and in the case of wood vessels the break of sheer was from 1in. to 2in. In the particular instance of the wood line-of-battle ship "Cæsar," which stopped on the launching ways, with a large portion of the after end of the vessel unsupported, the alteration in sheer was given to be as much as 18in. The author then proceeded to give full particulars of observations on the deflection of three types of vessels under various conditions of loading, but the details given are not suitable for abstraction. Finally, the writer expressed the hope that these investigations would tend to remove any doubts that have arisen as to the sufficiency of longitudinal strength in steel vessels built to the rules of Lloyd's Register Society to resist alteration of form when fully laden. Tabulated statements of the results were given, and diagrams of the vessels and curves, showing the displacement, sheering stresses, and bending moment, were also appended.

The discussion on this paper was opened by the Secretary reading a communication from Mr. Archibald Denny, who supplemented the observations given in the paper by others taken by his firm of the hogging and sagging of several vessels during launching, and when they were sea-borne. He thought, however, that the strains when the vessel was in a sea-way were much greater than during launching.

Professor Jenkins also cited some observations, and had supposed that the deflection in wooden ships was as much as 10in. to 12in. Though the author stated it as 1in. to 2in., yet other authorities put it at a higher figure. In spite of large deflection, however, there is not any considerable stress, as there is always some "give" owing to the rivets and other connections not being perfectly tight. The same occurs in iron vessels. He thought that some anomalies might be explained by the sights being set up on the deck and being interfered with by lateral as well as longitudinal movement. He did not think that an iron deck affected the deformation. The theoretical deductions from the observations should have been given. More important stresses must take place at sea than during the launch, but there are no data regarding them; the effect might be very great if the periods of oscillation of the vessel and the period of the waves agreed. Too much importance could not be attached to the necessity of straight keels and supporting blocks. No account of the variations in temperature appeared to have been taken in these experiments.

Mr. Martell stated that the sagging of vessels was often complained of, as it meant that as much as 100 tons less of cargo was carried or otherwise the Plimsoll mark went below water. He agreed that the keel must be kept straight, but did not see how lateral deflection was to be measured. Nor did he agree with Professor Jenkins' idea that the iron deck did not affect the question, since it prevented racking strains in the vessel. The paper was of value to the shipbuilding community.

Mr. Walter Phillips was able to give a continuation of the history of the first vessel measured by the author, as he had observed it during loading and unloading. The results, which he gave, were not satisfactory, and the vessel had to be strengthened. He knew that his figures would be criticised, but it was an undoubted fact that vessels often carried much less cargo than they ought to on account of sagging.

Mr. Ellis, of the Admiralty, said that the Admiralty built vessels on a concrete foundation, but in private shipyards it was often very difficult to keep the keel straight. He gave an example of shipbuilding in a Clyde shipyard, where they raised the after end of the keel half-an-inch to allow for settlement of the foundations.

Mr. Thompson said he arranged his sights on battens founded on the keel so that they were not affected by deck deformation. An iron deck prevented the sides of the vessel from coming in. The lateral deflection had been measured and found to be very small. His firm had hogged vessels when heavy boilers were to be put in.

In reply to the discussion, Mr. Phillips stated that the observed deflection of wooden ships in the Pembroke docks was never more than 2½in. His experiments had been performed during average weather. He did not at all agree with what had been stated by Mr. Walter Phillips.

The third paper read on Friday was by Mr. J. A. Yates, on

The Internal Stresses in Steel Plating due to Water Pressure.

This was essentially a mathematical paper, and dealt with a proposed method of calculating the stresses in the scantlings of the framing and the plating. The stresses due to water pressure are the most intense in the flattest parts of the plating exposed, and the calculations were confined therefore to such portions of the plating as are practically straight in both directions. A fore and aft strip of plating may be considered as a beam fixed at both ends, or as a suspension chain or parabolic arch uniformly loaded. Comparison of the formulæ for these two methods showed that if the deflection under pressure was less than one-sixth of the thickness of the plating, the strip considered would be bent under the conditions of a beam fixed at the ends; and if the deflection is greater than one-sixth of the thickness of plating, the strip would be bent as a suspension chain or parabolic arch. The question of side tension on the strips due to the connection with adjacent strips was very difficult to deal with. Further, the straining of the ship in a sea-way would seriously affect the stresses due to the simple water pressure. The author thought that the maximum deflection under pressure should be limited to about 0·05in. per foot of length for outside plating or ballast tank plating. Anything more than that might lead to possible damage of caulking and cracking of the cement. For bulkheads a somewhat greater deflection might, perhaps, be allowed without inconvenience; say, 0·1in. per foot. The stress allowed for local pressure straining should in the cases of the outer and inner bottom be limited to from 2 to 3 tons per square inch; but in the cases of bulkheads and water-tight flats, about 7 tons per square inch might probably be allowed with safety. From these facts and arguments it would appear that the course which should be followed in stiffening bulkheads was to fit substantial rigid stiffening frames at comparatively wide intervals, and only work such light angles between as were necessary for making a fair job of the bulkhead.

In the discussion which ensued, Mr. Smith said that he disbelieved in these theoretical calculations, as the results could not be proved unless the vessel broke down, or by examining her after long and arduous voyages. The only value in them was that they directed attention to what might be expected. Though steel makers were constantly producing stronger material, yet it was not safe to reduce the scantlings or plates in anything like proportion, as was seen when steel was used to replace iron. To prove that the author had overstated the stresses he cited the "Iris," a vessel of 20ft. draught. In that vessel the scantlings were 4ft. apart, but there was no question as to her strength.

Mr. Bryan, of Cambridge, had roughly calculated the form of the strip under pressure, and found that it was neither the catenary nor that of the ordinary beam, but an intermediate form. The true form might be ascertained by exact measurement, but the alternating thrusts and pulls that the plating had to sustain in practice would alter it considerably.

Professor Jenkins thought that the author had meant that the intermediate form should be inferred and that the practical results should be taken as a mean of the two forms given. The cumulation stresses due to the motion of the vessel in a sea-way were important, and would affect the water pressure stresses to a considerable degree.

Mr. Ellis considered each plate as a beam supported in two directions, by the scantlings and by the overlap of the adjoining plates. This gave a comparatively simple formula including the fourth power of the dimensions. From this he deduced the fact that the author's results were twice the proper value.

In replying to the discusssion, Mr. Yates said that he intended to take the mean of the results given in his tables. The bottom of the "Iris" was probably rounder than in the cases he had dealt with. In reply to Mr. Ellis, he said that the lap of the plates only gave partial support, and, moreover, transmitted the stress from one plate to the next.

At the Friday evening meeting Mr. Thomas Mudd read a paper, entitled

Some Details in Marine Engineering.

These, as will be seen from the paper which we conclude on page 320, related to the experience of the author in connection with the construction of boilers, the boring of stern frames, the machining of crank shafts, and the packing of pistons.

Mr. Fothergill said he had seven boilers built by Mr. Mudd's firm, working in ships under his supervision at 160lb. pressure, and they were most satisfactory. Annealing after working was very essential. One advantage of Mr. Mudd's construction was that, with a boiler low down in a ship and corroding at the bottom joints, the rivets were easily removed and replaced, whereas, with the usual radial rivets, it was only possible to get in screwed bolts. His experience of the pistons described was also satisfactory; they were noteworthy as giving no clicking noise, owing to the springs between the rings.

Mr. Milton could not see any great advantage in the boiler construction suggested. He said that 99 per cent. of boiler makers did not adopt it, and there must be some reason for this. The method necessitated annealing, while the ordinary way did not, and everyone knew the great difficulty of uniformly heating large plates. No flanging that he knew gave true surfaces, and there would be puckers in the boilers described as in others, while there were still three of the butt joints—which were so much condemned—left untouched. Another objection was the necessity of a larger space between the furnace and shell, and thus of a larger shell for the same heating surface and accessibility. The most difficult task in fitting crank shafts was in making the holes interchangeable. At Messrs. Hawthorn's they were bored from a standard block, and it had not infrequently happened that the lead of a crank could be changed by simply turning the shaft round one hole, without any other alteration being required.

Mr. Roundthwaite asked if the author's statement that there was always steam behind the piston rings was based on experiment or on reasoning. He thought there was probably always a film of steam between the rings and the cylinder walls, to which was due the smooth wearing of good cylinders. Experiments on rubbing surfaces had shown that cutting and grooving was only avoided when there was a cushion of oily matter between the surfaces, and a piston and cylinder would appear to be much in the same condition.

Mr. Mudd, in replying, pointed out that, although puckers did occur in his flanges, yet the method of fixing the ends was the best possible way of getting rid of them. He hoped some day to be able to turn the flange faces before riveting. His boiler required to be about 2in. larger in diameter for the same heating surfaces. This, he said, gave a larger water space, but that was a good fault. The butt joints left untouched were not in an important position, and were otherwise protected by inside straps. His statement as to steam behind the piston rings was based on reasoning only, but he thought it was sound.

Mr. David Joy afterwards read a paper on

An Assistant Cylinder for Marine Engines.

It described the experience of the author and his assistants in arranging an apparatus, which, while working automatically, should by its action assist the movement of the main slide valves, the object being to relieve the valve gear of the strains caused by the weight of the valve and the resistance due to its contact with the valve face, thus reducing the valve gear to a mere controlling mechanism. Diagrams and models of the apparatus were displayed, showing its progression from a complicated machine, as first designed in 1889, to a much simpler form, as at present fitted. Messrs. Laird, of Birkenhead, first gave orders for its attachment to engines for torpedo gunboats, and it has since been further adopted by them and by other firms. The fittings consist of a small cylinder fixed to the top of the main steam chest in place of the ordinary balance cylinder, and surrounding a piston attached to the prolongation of the valve rod. By the peculiar arrangement of the piston with its contained ports, and of other ports in the assistant cylinder, steam is made to act upon the piston in such a way that the main valve is

Digitized by Google

lifted, cushioned, moved down and cushioned again, precisely as best suits its desired motion. Diagrams were given showing the distribution of steam in the "assistant cylinder," and analysed to show the amount of "lifting" and "cushioning" effect. The construction is not more bulky than an ordinary balance piston.

Mr. Cobb opened the discussion, and described the construction and working of his own arrangement of balance cylinder, and its supposed merits over that shown by the author. His piston imprisoned a certain volume of steam as the valve descended, thus producing an effective cushion, while the expansion of this same steam produced an upward force lifting the valve. At the top side there was a similar but less powerful action. He pointed out that his arrangement used the same steam continually and required but little fresh supply, whereas that of Mr. Joy used a large amount of steam, and was thus expensive in working. A combination of the two forms of construction would be most likely to give a much better result.

Mr. Joy, Jun., had been on the trials of engines where this assistant cylinder was fitted, and could speak from practical experience as to its merits. Without the arrangement in use a distinct hard clacking was heard as the valve reversed its motion, but as soon as the assistant cylinder came into action this was succeeded by a soft sound as of the squeezing of a spongy washer. It was impossible not to notice the improvement it produced.

Mr. Joy, in a brief reply, pointed out that Mr. Cobb's arrangement would be found in an old patent specification of his own. They had met with no difficulty in getting rid of water from the cylinder.

There was another paper entered in the programme for reading and discussion, in the name of Mr. Haswell, of New York, on the

Construction of Crank and other Shafts for Marine Engines, and their Liability to Fracture,

but in the absence of the author a proposal was made by Mr. MacFarlane Grey that the paper be taken as read. This was ultimately agreed to, but not without some discussion, and a vigorous protest by several members against this being done without the addition of a note to the effect that the Institution did not therefore concur in the opinions therein expressed. It seemed to be the general opinion of members that the ideas embodied in the paper were not likely to receive approval. The remarks made suggested that the paper advocated methods of construction of very questionable value, all long since abandoned in this country.

THE PHYSICAL SOCIETY.

At a meeting of this Society, on the 20th ult., Professor W. E. Ayrton, F.R.S., President, being in the chair, Professor S. U. Pickering, F.R.S., read a paper on "The Theory of Dissociation into Ions and its Consequences." According to this theory, electrolytes are entirely dissociated into their ions in weak solutions. This dissociation was held by Arrhenius to absorb heat, and although heat is evolved by the dissolution of hydrochloric acid, &c., it is not maintained that dissolution evolves heat, but that the heat absorbed by the decomposition of the molecule into its atoms is more than counterbalanced by the heat supposed to be evolved by the combination of the atoms with their electric charges. These actions the author considered improbable, and thought that before being accepted, the theory must give satisfactory answers to the following questions:—How can matter combine with an affection of matter to produce heat? Whence do the electric charges originate? Why does not the opposite electrification of the different atoms make them cling more firmly together instead of dissolving the union between them? and Why should an atom which possesses a strong attraction for a negative charge (such as chlorine) go to the positive electrode during electrolysis?

When a dilute solution, which is supposed to contain some gaseous molecules, is further diluted, then, according to the theory, some of the molecules are dissociated, and, if heat is absorbed, it follows that the dissociation, and therefore dissolution, of the gas must absorb heat; yet, he said, it can be shown that in some of these cases the dissolution of a gas evolves a large amount of heat. The antagonism between the present, and the old electro-chemical theory, according to which the atomic charges are identical with the free energy of an atom, and are the cause of combination, not decomposition, was commented on, as well as the disagreement between the present theory and Clausius' view that there are a few ions or atoms present in a liquid owing to accidental superheating of some of the molecules. Reasons, however, were adduced for believing the presence of even a few atoms in a solution to be improbable.

A communication on "Some Points in Electrolysis" was then made by Mr. J. Swinburne. Considering a reversible single fluid cell, the author, by a process of reasoning based on Carnot's principle and the conservation of energy, arrives at Helmholtz equation $E = E_c + \theta \frac{dE}{d\theta}$, where E is the electromotive force, E_c the part due to chemical action, and θ the absolute temperature. Writing the equation in full, using suffixes n and p to denote the negative and positive plates, it becomes

$$E_n + E_p = E_{nc} + E_{pc} + \theta \frac{dE_n}{d\theta} + \theta \frac{dE_p}{d\theta}.$$

He then showed that by having the two plates in different vessels, and heating them to different temperatures, the Peltier effects, represented by $\theta \frac{dE_n}{d\theta}$ and $\theta \frac{dE_p}{d\theta}$, can be determined separately. Similarly those of a two-fluid battery might be found by arranging the junction of the fluids in a third vessel.

After pointing out the desirability that the conditions under which all thermo-chemical data have been obtained should be clearly stated, he proceeded to show that any cell in which secondary actions occur (as, for example, if zinc oxide primarily formed by electrolysis were to dissolve in sulphuric acid) must necessarily be non-reversible. He also contended that in a secondary battery, the formation of lead sulphate on both plates is the essence of the cell action, and that there is no intermediate formation of PbO. On the subject of so-called "nascent" hydrogen or oxygen, he said that reasoning from the conservation of energy showed that neither could exist. Taking the case of persulphate of iron in dilute sulphuric acid, which is said to be reduced to protosulphate by the "nascent hydrogen" liberated on putting a piece of metal (say magnesium) into the liquid, he said a better explanation of the phenomena would be that the metal dissolves if it either reduces the metal or evolves hydrogen, and as the former requires less energy, the reduction takes place, and, when no reducible salt is available, hydrogen is evolved. Evolution of hydrogen and reduction of the per salt are thus *alternative* and *not consecutive* actions. Examining Dr. Lodge's views on the contact e.m.f. between metals, he remarked that if the tendency of a metal (such as zinc) to oxidise can produce an electric stress or difference of potential which prevents further combination, actual combination must charge the metal, if it be insulated. A piece of sodium, however, oxidises continuously, and therefore should become charged to an enormous potential. As this effect is not known to occur, the author suggested that the volta effect may be due to films of water, and in support of this view adduced the fact that metals, when perfectly dry, do not combine with chlorine, and that even sodium is not attacked by dry chlorine.

In the discussion on the two papers, Professor Pickering said the idea of nascent elements had, to a large extent, been given up by chemists, and pointed out that the fact of one reaction taking place rather than another was not merely a question of heat energy, but that a kind of chemical selection was involved.

Professor S. P. Thompson recalled attention to the fact that the products of electrolysis depend on the e.m.f. employed in producing it, and thought the e.m.f. required to produce the various products might be taken as a measure of their affinities. He did not agree with Mr. Swinburne's method of finding the e.m.f. of a secondary battery from thermo-chemical data, for he failed to see how two similar actions going on at the two plates of a cell could add anything whatever to the e.m.f. of the cell.

The President said the question whether the potential difference between two dissimilar substances was due to oxidation or to mere contact could only be decided by direct experiments made in a vacuum from which all traces of moisture and oxygen had been removed. Without agreeing with Dr. Lodge's view on the subject, he pointed out that the continuous oxidation of a piece of insulated sodium need not necessarily produce a great potential difference, for the combination might produce heat.

After Professor Pickering and Mr. Swinburne had replied to the points raised, Mr. Walter Bailey took the chair, and Professor Perry read a note on "The Variation of Surface-Tension with Temperature," by Professor A. L. Selby, M.A. Considering unit mass of liquid at constant volume, but variable surface (S) and temperature (t), the author expresses the gain of intrinsic energy due to changes of the variables by $dH + dW = k dt + (l + T) dS$, where dH is the heat absorbed, dW the work done on the film, k the specific heat at constant volume, l the latent heat of extension, and T the surface-tension. This being a perfect differential, it is shown that $T = c - b t$, and $l = b t$, c and b being constants. Supposing c and b to be independent of the specific volume of the liquid, it is shown that at the critical temperature $t = c/b$, hence this temperature may be determined by finding the surface-tension at two very different temperatures. Since also $l = b t$, the latent heat of extension is proportional to the absolute temperature. Reasons for supposing b to be independent of the specific volume are given in the paper.

Mr. Blakesley described an effect of temperature on surface-tension which he had observed in sensitive spirit levels. By warming one end of the tube, even by the hand, the bubble immediately moves towards that end. This effect, which might produce considerable error in engineering operations, was, so far as he was aware, not mentioned in the text-books.

Professor Perry remarked that, although the volume, temperature, and surface of the liquid had been referred to in the paper, pressure was not mentioned, and on this point he inquired whether the results arrived at were true, quite independent of the pressure.

Professor S. P. Thompson, D.Sc., afterwards read a paper on "Magnetic Proof Pieces and Proof Planes." The distribution of magnetism over magnets has been examined in various ways by different observers, but mostly by observing the force of detachment of either rods, ellipsoids or spheres, used as proof pieces. In all these cases it was, the author said, difficult to see exactly what was measured, for the presence of the proof pieces altered the thing to be tested. The pull exerted must also depend on the permeability of the piece used, as well as on its shape and disposition with respect to the magnetic circuit. He had, therefore, investigated the subject by finding the actual distributions by means of a flat exploring coil and ballistic galvanometer, both with and without the presence of proof pieces of various shapes and sizes. The results show that the perturbations produced by the proof pieces are always large; in some cases the perturbed field about a point being four to six times the unperturbed field. In most cases, however, the ratio of the perturbed to the unperturbed field was constant, so long as the former did not exceed 6,000 G.G.S. units. The amount of perturbation was also found to depend on the saturation of the magnet, and on whether it was a permanent or an electromagnet. The numbers obtained in various experiments, and curves plotted from such results, were shown. In conclusion, the author said that, in using proof pieces, much depended on the accuracy of the contact, but in any case the results obtained were not very reliable. The flat exploring coil, or magnetic proof plane, however, furnished a satisfactory method of examining magnetic distributions.

THE MANUFACTURE OF SOAP.

By W. Lawrence Gadd, F.I.C., F.C.S.

(*Continued from page* 307.)

II.

The Manufacture of Soap.—The soaps commonly made in this country may be roughly classified as follows:—(1) Household soaps, comprising curd, yellow, brown, and mottled; (2) soft soap; (3) manufacturer's soap; (4) toilet and medicated soaps; (5) soap powders.

These various kinds are manufactured mainly by one of three processes, viz.:—(*a*) By the action of free fatty acids on caustic alkalies, or the carbonates of the alkali metals; (*b*) by acting on neutral oils or fats with the exact quantity of caustic alkali necessary for their complete saponification (as in the so-called "cold process"), the product retaining the glycerine resulting from the decomposition of the oils; (*c*) the ordinary and most commonly used process of boiling the fats or glycerides with caustic soda or potash in open pans, the indefinite amount of alkali used being left entirely to the experience and judgment of the soap-boiler. By this process are manufactured both soaps which retain the glycerine, as, for example, soft soap and marine soap, and those, like the ordinary hard yellow varieties, from which the glycerine is eliminated and subsequently recovered.

By far the largest quantity of soap made in this country is manufactured by the process last mentioned, which essentially consists in boiling the fats with solutions of caustic soda or potash of such strength as is found by experience to be the most efficient, until combination takes place, and in the case of soda soaps, the separation of the glycerine, superfluous water, &c., by the addition of brine. In order, however, to effect complete saponification, and to obtain the soap in a condition suitable for the market, it is necessary for it to pass through several processes or stages of manufacture, each having a definite object, and, as a rule, occupying several hours in working.

The oils or fats intended for the operation are first steamed out of the casks or hogsheads into partially covered iron tanks, from which the melted fat is pumped up into the soap pan. It is the practice at some works to sink these tanks or wells into the ground, until their upper edges are only slightly above the level of the floor of the melting-out shed. The full casks are rolled along inclined shores until they are brought directly over the opening in the top of the tank, when a steam pipe is inserted and the fat blown out of them. Before passing into the well, however, this fat should be strained through a piece of metal gauze placed underneath the cask or fixed over the opening in the tank. The method of sinking the tanks is, however, open to serious objection,

Digitized by Google

because it is almost impossible to prevent dirt from being brought into the shed by the workmen and finding its way into the oil wells during bad weather, and also on account of the danger of such a tank leaking to a considerable extent without any cognisance of the fact. Some time ago it became necessary, at one of the soaperies in the North of England, to remove a tank which had been thus sunk in the ground for some years, when it was discovered, for the first time, that there had

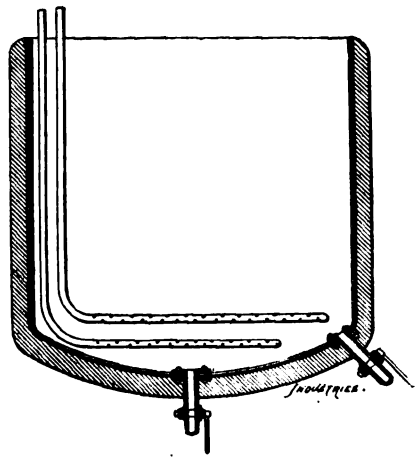

Fig. 1.—Sectional Elevation.

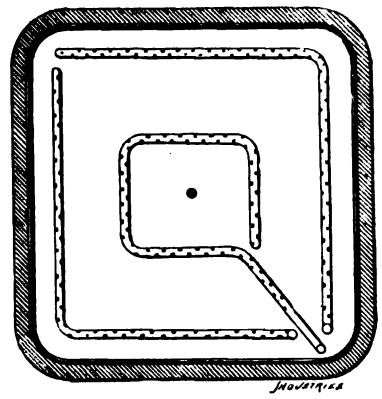

Fig. 2.—Plan.

been a leak, and the ground for a considerable distance round the tank was found to be saturated with oil. A far better plan is to have the whole of the melting-out tanks above ground, the working platform of the shed being from 6ft. to 8ft. above the floor level. The casks can be raised to this platform either by rolling them up an inclined plane or by means of a crane or other mechanism. Messrs. Lever Bros., of Port Sunlight, employ two or three special steam platform lifts with long cylinders for this purpose. The height of the melting stage is 7ft. above the floor level, and the platform of the lift, when carrying a full cask, is raised to this height by a single stroke of the piston. These lifts answer every requirement, and a large number of barrels can be raised by one of them in a very short space of time.

The method of preparing the caustic soda lye, by the double decomposition of soda ash and quicklime, has practically become obsolete, and the alkali is now obtained in a more convenient form as solid caustic soda, generally of 60 or 70 per cent., in iron drums holding about 5 cwt. each. To facilitate solution the solid block of caustic is broken to pieces, while still in the drum, by striking it all over with a heavy hammer. The drum is then placed over or near to the lye tank, cut open, and the broken-up contents thrown into the well, which contains water kept boiling by means of steam coils. The strong solution of caustic thus prepared is next diluted to a definite strength and pumped into storage tanks, placed at a higher level than the soap pans, into which it can be run, as required, by gravity. As a rule, the caustic lye is prepared as required, and is consequently used before it has deteriorated to any extent by absorbing carbon dioxide from the air, but in case of necessity it may be stored, without loss of strength, for a considerable time, if a quantity of paraffin wax be thrown into it while hot. The melted wax forms a protecting crust on the surface of the solution, and effectually prevents the absorption of carbonic acid.

The boiling pans, in which the combination of the alkali with the fatty matter is brought about, may be either round or square, but the latter is the shape now almost universally employed in modern factories. These are rectangular iron vessels with rounded corners and dished bottoms, 12ft. or 14ft. square, and about the same in depth (see Figs. 1 and 2). Each pan is provided at the bottom with perforated steam coils, one of which passes along two sides of the pan at a short distance therefrom, a second runs along the remaining two sides, whilst a third is placed in the centre of the pan. Each of these coils is provided with a separate steam cock, which should also have below it a tap for the egress of condensed water and possible leakage of steam when the main cocks are closed. The pans are covered on the outside with a thick layer of some non-conducting material, to prevent, as far as possible, the radiation of heat, and, both on this account and for convenience in working, are preferably placed together in rows, either in the centre or along the sides of the boiling house, which forms the top floor of a soapery. Over the pans run pipes for the conveyance of the melted fat or oil, with taps for delivering these substances into any particular pan, and there are also pipes for water and for the caustic lye.

(*To be continued.*)

Notes.

DEVELOPMENT OF THE TELEGRAPH SYSTEM.

From a Parliamentary paper recently issued we may see the marvellous increase in our inland telegraph system. In the year 1870, when the telegraphs were taken over by the Government, the total revenue was £612,301. Five years later it had risen to £1,533,982; in 1880 it was £1,469,795; in 1885, £1,820,764; and last year it was £2,364,098.

COAL IN NEW MEXICO.

The extent of the coalfields of New Mexico is not generally known, and consist of the Raton fields, an extension of the Colorado fields, and embrace about 600,000 acres of the best bituminous coal, of good coking quality. The mines have now a capacity of 500 tons per day. There are also other coalfields, besides deposits of gold, silver, and copper ore. The hills are full of undeveloped mines of iron, with coal enough to work them.

THE ELECTRIC LIGHT IN CALCUTTA.

It is stated that the Howrah Bridge is shortly to be lighted by electricity, which will be a very great improvement upon the present system of lighting. At present, indeed, the bridge is very badly lighted, there being no lights at all upon the moveable section, which is 200ft. long. The remainder of the bridge and the boat opening below, are also very indifferently lighted. It is now proposed, states the *Indian Engineer*, however, to place thirteen arc lights on the roadway of the bridge, each of 2,000 candle-power; and four similar arc lights for the boat openings, with eighteen strong incandescent lights for the signal stations, watch-house, and engine-house. The aggregate lighting will be equal to 34,384 candles, and to prevent the possibility of failure, the plant will include a spare engine, boiler, and dynamo. The contractors are Messrs. Laing, Wharton, & Down, of London, who have been selected to supply the electric lighting plant for the Kidderpore Docks. The cost of the Howrah Bridge plant is to be Rs.42,050.

THE NEW NAVAL DOCK AT BANGKOK.

One of the largest public works as yet undertaken by the Government of Siam is the new Naval Dock at Rong Lau, Bangkok, which was opened recently in the presence of the King of Siam. The new dock is 300ft. long, and has its entrance from the river. It is closed by a caisson, which fits into a groove in the masonry. The bottom of the dock is below low water, and a steam engine and pumps on shore, with a well and water channel leading to it, are used for emptying it. The engine is stationary, placed in a shed convenient to the dock, and the two pumps have been supplied by Messrs. J. & H. Gwynne. They are of the now well-known centrifugal kind, and it is claimed that the efficiency is as high as 70 per cent. According to the *Indian Engineer* the dock is emptied by means of these pumps in from five to six hours. The outside embankment is constructed with piling from 32ft. to 38ft. in length, and secured with iron stays fastened on a double row of anchorage piles. All the outside framework is metal-plated to the height of immersion, for protection against the *Teredo Navalis*. The floor of the dock is nearly level. As Siam is so rich in wood, the sides of the dock have been made of strong teak in the form of four steps, and the length and breadth are such that in an emergency the dock can hold two vessels at one time, though in that case they would not be placed in the centre line, but obliquely, so as to give more available length. The contractors for the new dock were Messrs. Grassi Bros. & Co. The total cost of the dock alone is about $40,000.

TELEPHONES IN CALCUTTA.

We learn from the report of the Bengal Telephone Company, Limited, for the year ending 31st December, 1890, that, on that date, 437 exchange and private lines were at work, yielding a revenue of Rs.76,400. The improvement of the telephone service is a matter on which great attention has been bestowed, and in Howrah, and to the south of the Exchange in Calcutta, faults on the line are now rare. There is still room for improvement in the centre and north of Calcutta. As extensive repairs and alterations had to be made to the building of the Central Exchange, the opportunity was taken of entirely reconstructing the switching arrangements. A new derrick, states the *Indian Engineer*, has also been erected on the roof, and the Exchange is now capable of receiving 800 wires. These measures are not yet complete; but, though costly, it is believed they will be real and permanent improvements. In the last report reference was made to an attempt at opening up business in Cawnpore, but the efforts of the company to induce the Government to allow the police stations to be connected, as is the case in Calcutta, Bombay, and Rangoon, have not been successful, and the balance of the Cawnpore account has been written off, as there is now no hope of opening an exchange.

ALUMINIUM FOR INCANDESCENT LAMPS.

Various substitutes for platinum for leading-in wires for incandescent lamps have been proposed from time to time. Iron was proposed by Mr. Ward some eight years ago, but never came into use. Iron and nickel both stand the blowpipe fairly well if enamel is used, but they give off so much gas in the form of minute bubbles that it is impossible to seal them in properly. Copper has been proposed, and Mr. Crookes proposed copper coated with gold. The fusing point of copper is low, however, and this makes its use difficult. The latest proposal comes from Cincinnati. Mr. McGregor, of that city, is reported to have succeeded with aluminium. This metal is generally used for electrodes for vacuum tubes, but platinum is adopted to make the connections through the glass. Anyone trying to seal aluminium into glass will find that a skin forms on its surface, and the glass cracks on cooling. The low melting point of the aluminium also gives rise to difficulties. Aluminium has not only a strong affinity for oxygen and other acid radicles, but the metal itself absorbs silicon with avidity. No doubt it thus attacks the glass, and forms a skin of silicate of alumina, while the metal itself absorbs silicon. We are, therefore, a little sceptical as to the use of aluminium for leading-in wires.

EXHIBITION AT DUNKIRK.

An Exhibition is to be held at Dunkirk during the present year. The Exhibition, which will be opened for a period of five months from May 1st to September 30th, has for its object the extension of commerce and industry in the Nord and Pas du Calais Departments of France, and will be devoted to the following subjects:—Industry, Agriculture, Commerce, Shipping, Science, and Fine Arts. These subjects will be divided into the following ten groups, one of which, it will be noticed, is an international one:—

Group 1. Food Stuffs.
2. Educational Instruction and Professional Teaching.
3. Furniture and its Accessories.
4. Textile Industries and Clothing.
5. Industrial and Agricultural Products.
6. Agricultural and other Machinery, Tools.
7. Architecture, Hygiene, &c.
8. Horticulture.
9. Fine Arts.
10. International Section.

The various French railway companies are offering facilities for the conveyance of exhibits, which will also be extended to exhibits for the international section. During the period that the Exhibition will be open various competitions will be held, and also several special *fêtes* are being organised to make the Exhibition as attractive as possible and to ensure its success. Full particulars regarding the Exhibition can be obtained by applying to M. Alexander Meyer, Commissaire-Général-Adjoint, 11, Rue de Rocroy, Paris.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

16th March, 1891.

4624. Pickles & Pickles ..... Looms.
4637. Hall & Morel ..... Grinding mills.
4644. Arnold, J. O..... Manufacture of steel ingots and apparatus therefor.
4655. Brownhill, W..... Manufacture of metal tubes and machinery therefor.
4661. Mills, W..... Manufacture of alkali and apparatus therefor.
4668. Taylor, G. (of Taylor, Cooper, & Bednell, Ld.) ..... Machinery for making metal balls or spheres.
4674. Brownell, G. L. ..... Twisting machines.
4676. Bowker & Williams ... Looms for weaving.
4685. Riley & Burke ..... Apparatus for bending or curving cold iron plates.
4690. Pickard, A..... Square hole drilling machinery.
4694. Boult, A. J. ..... Wheel driving mechanism (*Zieger*).
4695. Baldwin, W. A..... Process and apparatus for alloying metals.
4697. Yates, J. ..... Safety devices for lifts, hoists, &c.
4699. Angove & Watkins..... Boat suspension and detaching gear.
4702. Griffiths, W. ..... Magazine firearms.
4705. Craven, P. P..... Spinning frames.

17th March, 1891.

4716. Longsdon, A..... Self-acting brakes for field gun carriages (*Krupp*).
4724. Wright & Hill ..... Apparatus for casting multiple ingots in steel or other metals.
4728. Brown, A. G..... Metal founding machines (*Tabor*).
4730. Marriott, C. ..... Apparatus used in the manufacture of sulphate of ammonia.
4732. Pickup, J. ..... Shuttle guard for looms.
4733. Waddington, J..... Tongue rests for loom shuttles.
4734. Morton, J. ..... Machinery for making pipes, retorts, and other goods from clay.
4755. Card, W. L. ..... Concentrators.
4761. Lake, H. H..... Machines for cutting tinplate or other sheets into blanks (*Hodgson*).
4765. Simonson, F. ..... Machinery for handling logs in saw mills.
4771. Cooper, E. W. ..... Gas and vapour engines.
4776. Morgan, F. F. ..... Fire alarms.
4795. Vavasseur, J..... Gun mountings.
4796. Gollings, E. H. ..... Rotary pumps and engines.
4798. Boult, A. J. ..... Gas generators for motor engines (*Compagnie des Fonderies et Forges de l'Horme & Lencauchez*).

18th March, 1891.

4806. Dunlop, J. ..... Compound locomotive steam engines.
4809. Leeder, F. G..... Apparatus for making moulds for castings.
4822. Barnett, D. ..... Apparatus for combing fibres.
4823. Cooke, W. ..... Steam boilers.
4830. Garrett, L. P. ..... Gas engines.
4843. Tresidder, T. J. ..... Dividing apparatus for lathes.
4849. Franke, E. ..... Lubricators.
4851. Stone, R. ..... Machinery for crushing, grinding, pressing, rolling, smelting, and burning purposes.
4862. Lindemann, O. ..... Gas and petroleum engines.
4863. Lake, H. H..... Harness depressing devices for looms (*Stafford*).

19th March, 1891.

4887. Willey, D. H. ..... Engaging and disengaging apparatus for ships' boats.
4892. Lamb, J. ..... Jacquard looms.
4896. Biddles, G. H. ..... Mechanical firebars for destructor or other furnaces and a feed hopper for charging same.
4897. Fletcher, Fletcher, & Fletcher ..... Reverberatory furnaces.
4903. Higginson, A..... Steam winch.
4907. Wright, W. ..... Steam boilers.
4920. Howden, J. ..... Compound steam engines.
4921. Howden, J. ..... Apparatus for supplying air to the furnaces of marine boilers
4924. Johnson, J. W. ..... Scouring machines.
4928. Young & Crippin..... Apparatus for dyeing and bleaching cotton, wool, &c.
4934. Fox, F. W. ..... Spinning and twisting machines.
4936. Storm, J. ..... Lubricators.
4939. Boult, A. J. ..... Railway carriage brakes (*Milburn*).

20th March, 1891.

4965. Lord, Mills, & Newall Opening, scutching, and carding machines.
4966. Perry, J..... Steam engine indicator.
4987. Cory, Reynolds, & Catford ..... Mortising machines.
4991. Powell, D. T. ..... Cylinder printing machines.
4993. Royle, J. J. ..... Valves.
5001. Wenham, F. H. ..... Cocks or valves.
5008. Gardner, G. H..... Machinery for the manufacture of chains (*Brown & Cady*).
5018. Oates, S. ..... Steam boiler furnaces.
5030. Fraser, J. H. ..... Securing tubes in plates of boilers.
5035. Utting, J. A. ..... Fog-signalling apparatus.
5042. Dunaway & Dunaway... Engine governors.
5046. Von Skoda, E. R. ..... Quick-firing guns.

21st March, 1891.

5050. Johnson, T..... Printing machines.
5054. Borchardt, O. ..... Boiler tube scrapers.
5063. Joy, D. ..... Valves of steam engines.
5072. Lanchester, F. W. ..... Gas engines.
5073. Hedley & Jones ..... Balanced slide valves.
5074. Parsons, C. A. ..... Steam turbines.
5083. Munns, W. H. ..... Brakes for railway cars (*Englis & Schierman*).
5084. Munns, W. H..... Car coupling (*Lankford & Langford*).
5085. Munns, W. H..... Rotary engine (*Everest & Betterman*).
5116. Charpentier, E. ..... Wire working machines.
5121. Patten, W. ..... Machine for straightening and bending angle and tee iron.

ELECTRICITY.

16th March, 1891.

4669. Hirbec, V. ..... Apparatus for utilising heat as a source of electricity.
4678. Pilkin, J..... Terminals for electrical purposes.
4682. De Ferranti, S. Z. ..... Arrangement for electrical systems.
4689. Challis, C. E. ..... Switches.

17th March, 1891.

4715. Amstutz, N. S. ..... Process of and apparatus for electrically reproducing uneven and irregular surfaces.
4740. Attree, G. F..... Electric railway signals.
4751. Imray, O..... Electrical transportation systems (*Wheeler & Bradley*).
4757. Willson, T. L. ..... Electric reduction of aluminium and other metals and the production of alloys thereof.
4758. Clark, A. M. ..... Electric railways (*The Waddell-Entz Electric Company*).
4781. Engledue, W. J. ..... Solution for galvanic batteries.
4794. Kingsbury, J. E. ..... Signalling and telephonic systems (*The Western Electric Company*).

18th March, 1891.

4812. Millar, H. A..... Incandescent lamps.
4831. McGeoch, Jun., & McGeoch..... Holders for incandescent lamps.
4838. Bailey & Warner ..... Incandescent lamps.
4860. Howard, H..... Apparatus for heating and welding by the electric arc.
4869. Lake, H. H..... Primary and secondary batteries and the manufacture of electrodes therefor (*Desruelles*).
4881. Clark, A. M. ..... Electric railways (*S. Schuckert & Co.*).
4882. Duck, F. J. ..... Electric indicators.

19th March, 1891.

4949. Johnson, J. Y. ..... Galvanic batteries (*Tardy*).

20th March, 1891.

4988. Thompson, W. ..... Printing telegraphic instruments.
5003. Johnson, J. Y. ..... Holders for incandescent lamps (*Mace*).
5021. Lake, H. H. ..... Accumulators (*Gandini*).
5043. Money & Nash ..... Arc lamps.

CHEMISTRY.

16th March, 1891.

4696. Butterfield, J. C. ..... Treatment of tinned iron for the recovery of the tin and other products.

18th March, 1891.

4820. Beilby, G. T. ..... Process and apparatus for the manufacture of cyanides.
4871. Willcox, B. ..... Colouring matters derived from anthra - quinone (*Farbenfabriken vormals Friedrich Bayer & Co.*).
4878. MacDonald, J. M. ..... Method of liquefying carbonic acid gas and storing same.

20th March, 1891.

5027. Von Brauk, E. ..... Explosive compositions.

21st March, 1891.

5103. Read Holliday & Sons, Ld., Holliday, & Seidler ..... Manufacture of a sulpho acid of alphanaphthol and of colouring matters therefrom.
5104. Read Holliday & Sons, Ld., Holliday, & Seidler ..... Azocolouring matters.
5122. Willcox, B. ..... Production of ortho-oxydiphenyl-carbon acid (*Von Heyden*).

MISCELLANEOUS.

16th March, 1891.

4626. Burghes, J. McL. ..... Joint for drain pipes.
4630. Fraser, N. ..... Brackets for belt guiding pulleys.
4638. Cooper, A. ..... Propellers.
4656. Merington, C. ..... Shells or other projectiles.
4658. Pickles & Pickles ..... Mode of manufacturing healds for weaving.
4663. Ware, T..... Wrench (*Rogers*).
4681. Downing, D. F..... Packing piston rods and the like.
4709. Westaway, J. ..... Fire escapes.

17th March, 1891.

4713. Reusch & Peru ..... Casting of hard metal or chilled rolls.
4793. Middleton, W. B..... Treatment of steel.

18th March, 1891.

4859. Isaac, P. L..... Supplying air to the furnaces of marine boilers.

19th March, 1891.

4947. Maughan, B. W. ..... Propellers.

21st March, 1891.

5080. Munns, W. H..... Railway sleeper (*Jeffers & Girin*).
5082. Munns, W. H..... Nut lock (*Harvey*).

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1890.

4328. Scott & Thornton.
4356. Wilkinson.
4461. Hornsby & Smith.
4653. Davies.
4740. White.
4824. Nebel.
5567. Shaw & Rollason.
5771. Cawdery.
5903. Healey.
5970. Ashley.
6075. Maynard.
6134. Farrow.
6333. Lyte.
6422. Jones & Jones.
6650. Leigh (*Jeansaume*).
6716. Chambers.
6817. Aish.
6883. Clarke.
6952. Kellner.

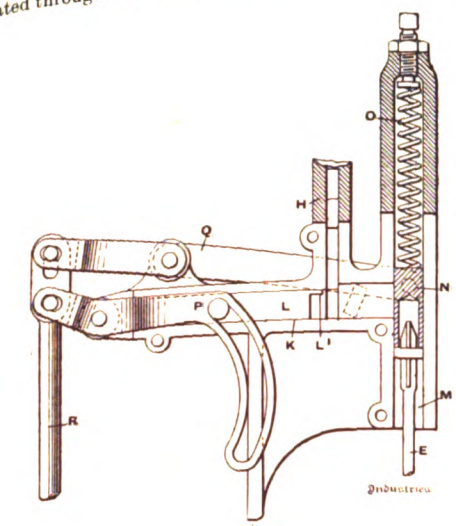
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Machinery for Tapping Nuts.—*W. P. Thompson, London.* (*F. S. Cook, Springfield, Ohio, U.S.A.*)—The machine for the above purpose is shown in sectional elevation in Fig. 1, Figs. 2 and 3 being enlarged details thereof. The main shaft A driven from A^1 drives by suitable gearing the tool chuck B and by worm

gearing the shaft C. This tool chuck has on it a revolving sleeve D in a groove in which fits a yoke of a pivoted lever D^1 actuated by a cam on the shaft C, so giving D an intermittent vertical reciprocating motion. The tap E is held between two pairs of jaws F F^1 (Fig. 2), which are alternately allowed to release the tap as the sleeve D rises and falls by the ends of suitable set screws in the latter acting on the heels on said jaws. In this manner the nuts which have been passed over the tap are allowed to escape. The nut blanks are fed from the hopper G, which has an inclined bottom, through an orifice G^1 in the lower part thereof into an inclined trough H. The hopper G is given a slight horizontal reciprocating motion, so as to feed the nut blanks regularly into H, by means of a rack lever, teeth on one end of which engage teeth on the lower part of G and a stud on the other end of which projects into a cam groove on the periphery of the wheel I driven from J. The blanks one by one are fed from the inclined trough H into the horizontal channel K (Fig. 3), and are then forced forward by a plunger L, and by means of a tongue L^1 tilted over on to their faces, and are so forced into the vertical channel M beneath the plunger N. This plunger is then caused to descend, and a spring O forces the nut blank upon the tap. In the meantime the plunger L has been carried backwards, and at the same time N rises and the action is repeated. The plunger L is operated by a radial slot in a lever P engaging a pin thereon, the lever P as well as the lever Q operating the plunger N being actuated through a rod R from a cam on C. The lubrication of the



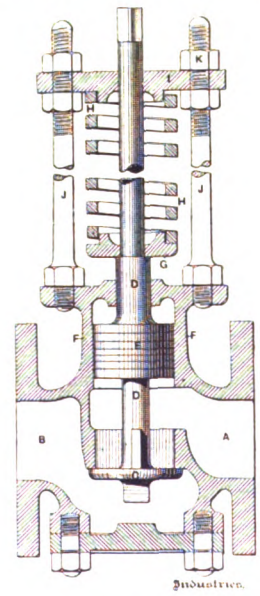


FIG. 3.

various parts is effected by means of a pump S operated from the main shaft and pipes T. The inventor describes several modifications of the tool chuck. Claims: (1) A nut tapping machine having in combination a feed hopper for the blanks, a counterbalanced feed conduit adapted to receive the blanks one by one from said hopper and to convey them all in the same position towards the tap, and means whereby an excess of blanks over a given amount in the conduit will tilt the same and automatically check the feed of blanks from the hopper; (2) in a nut tapping machine, a continuously revolving upright chuck or pair of chucks having two sets of jaws for gripping the tap at two points in its length, in combination with mechanism adapted to open and close said sets of jaws successively, whereby the nuts are permitted to drop from one set on to the other and then off the end of the tap without the necessity of bringing the tap to a standstill; (3) the means whereby a nut blank is carried forward in its proper position over the tap and is held in contact therewith by spring pressure until engaged with the tap; (4) the combination, with the continuously operating tap, as described, of the delivery spout, the oil pan, pump, and oil conduits.—No. 9242. June 14th, 1890. 11*d.*

Pressure Reducing Valves.—*J. Kirkaldy, London.*—A reducing valve such as is embraced by the present invention is shown in sectional elevation herewith. A represents the inlet for steam and B the outlet, C is a disc valve closing the passage from one to the other, D is the valve stem, which is prolonged upwards, and has upon it a piston E fitting within a

cylinder F, which is of the same diameter as the opening through the valve seat. The pressure of steam upon the top of the valve is therefore balanced by the pressure of steam on the bottom of the piston. The stem D is prolonged above the piston and made to pass out through the top of the cylinder F. Outside the stuffing box it has a disc G fixed upon it, against which a coiled spring H is made to bear. The upper end of the spring rests against a bar I, which is held fast at a distance from the top of the cylinder by two rods J. These rods are at one end secured to a flange around the top of the cylinder, and at the other are made to pass through holes in the bar, and have screw threads cut upon them on to which are screwed nuts K, and by these nuts the bar is locked to the rods. By screwing the nuts along the rods the bar can be fixed at any desired distance from the cylinder, and so any desired pressure can be put upon the spring. The valve C is held open by the action of the spring, and steam or other fluid under pressure passes from the inlet to the outlet until the pressure in the outlet is sufficient to overcome the downward thrust of the spring and to press the valve upwards and close it. Claims: The reducing valve constructed substantially as described.—No. 5277. April 5th, 1890. 6*d.*

Machine for Charging Gas Retorts.—*C. Eitle, Stuttgart, Germany.*—The apparatus embraced by this invention is for the purpose of charging horizontal gas retorts. A tramway is made in front of the charging ends of the retorts, on which runs a carriage carrying a framework on one side of which the charging apparatus slides, said apparatus being connected to a suitable balancing weight by means of cords or chains passing over pulleys fixed on a shaft journaled at the top of the framework, and carrying a large grooved wheel around which passes an endless rope. By means of the latter the said wheel may be revolved, and so the charging apparatus may be raised or lowered. The charging apparatus consists essentially of a hopper, into which the coal is fed. Connected to the lower end of this is one end of a horizontal cylindrical chamber, in which revolves an open screw, which feeds the coal forward from the receiving to the delivery end of said chamber. The delivery end of said chamber is connected to the upper part of a drum, in which revolves suitable wings to impel the coal supplied to it through a suitable horizontal shoot connected to the lower part thereof into the retort to be charged. A driving shaft is journaled on the upper part of the drum and is connected by suitable gearing to the shaft operating the open screw and wing propellers. In two claims the inventor embraces the apparatus substantially as described.—No. 17921. November 7th, 1890. 6*d.*

Compound Steam Engines.—*R. Richardson, Inchinnan Road, Renfrewshire, N.B.*—The inventor's object is to so construct compound double-acting engines that the pressure on the crank and cross-head pins and main bearing is always in one direction, and also to provide an improved means of slightly rotating the pistons when the latter act as the steam distributing valves. In the annexed illustrations is shown in Fig. 1 a front sectional elevation, at Fig. 2 a side sectional elevation, and at Fig. 3 a sectional plan through the cylinders of a compound engine embracing these improvements. The high and low pressure cylinders A and A^1 are connected at about midway in their length by passage B, diametrically opposite which are the supply and exhaust ports B^1. Ports are formed in the pistons of A A^1 leading to the upper and lower ends thereof, which, as the pistons are revolved, are brought opposite the ports B and B^1 in such a manner as to supply and exhaust steam from the opposite ends of the cylinders. The rods of these pistons are connected to slides C C^1, to the underside of which are connected by a ball joint D the rods E, the lower ends of which embrace the main crank shaft F. The slides C C^1, and so the pistons of A A^1, are revolved by a tooth on the upper ends of E engaging teeth on the underside of C C^1. The pressure on the main crank shaft, &c., is effected by means of a lever G pivoted at G^1, the ends of which press upon the upper faces of C C^1, the lever and its pivot being forced downwards by means of a screw H. Four claims are made.—No. 8824. June 7th, 1890. 8*d.*

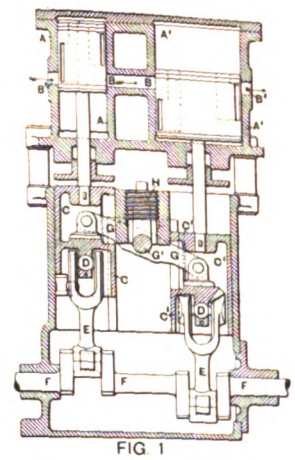

FIG. 1

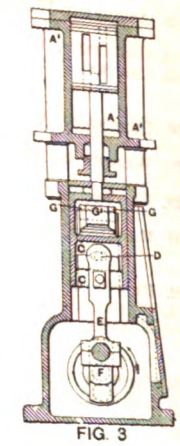

FIG. 3

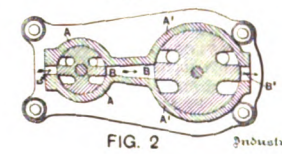

FIG. 2

Steam Engines.—*P. W. Willans, Thames Ditton, Surrey.*—The inventor's aim is to prevent the collection of water of condensation in the working cylinders of steam engines. To effect this two annular grooves or recesses, one at each end, are formed in the working surface of the cylinder, in which are arranged small steam pipes, whose ends are connected to the supply and exhaust pipes of the engine or otherwise supplied with steam. The ends of the piston and the grooves are so formed that any water of condensation in the cylinder will be forced into one or the other of said annular grooves, where it becomes converted into steam by the heat of the small steam pipes. Claims: (1) The method described for preventing the accumulation of water in the steam engine, such method consisting in applying heat to a small receptacle, which receives the water condensed in the cylinder by means of a steam pipe or similar heater so arranged in the said receptacle as to become immersed in the water contained therein as soon as an appreciable quantity of water collects, and so keeping such receptacle and its contents hot relatively to other parts of the cylinder; (2) the combination with the cylinder of a vertical steam engine of receiving cavities and heating pipes as described.—No. 6354. April 25th, 1890. 6*d.*

Digitized by Google

ANTI-FRICTION JOURNAL BOXES.—*T. N. Subers, Philadelphia, Pennsylvania, U.S.A.*—Two loose rings are placed upon the journal of the axle or shaft, and are held at a suitable distance apart by means of stay bolts. Journaled in recesses in the opposite faces of these rings are the anti-friction rolls, the peripheries of which project beyond the inner and outer peripheries of the two rings, and are of a diameter equal to the space between the journal and the journal box. Between each of the ends of the journal box and flanges on the journal are held two other rings in which are journaled radially other anti-friction rolls. The peripheries of these project beyond each side of the ring, and are in contact on one side with the end of the journal box, and on the other side with the flange on the journal. In two claims the inventor includes the general construction and arrangement of anti-friction journal boxes substantially as described.—No. 19427. November 28th, 1890. 6*d.*

APPARATUS FOR PRODUCING OXYGEN GAS.—*R. D. Bowman, East Dulwich, Surrey.*—The preparation of the material for the above purpose is, according to this invention, effected by first half filling a suitable closed vessel with sodium hydrate and

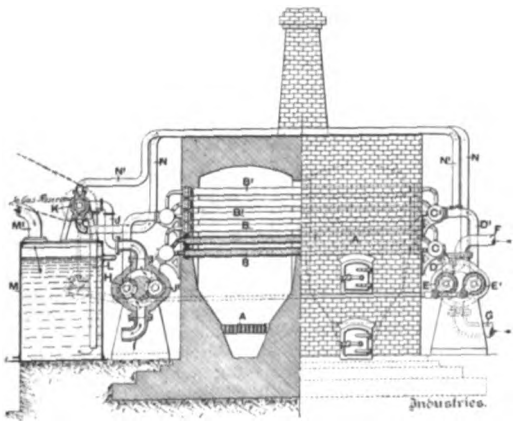

FIG. 1.

raising it to a red heat, and maintaining it so until ebullition ceases Small quantities of sesquioxide or peroxide of manganese are then added until the mass attains, after constant stirring, a plastic granular condition. The proportion of sodium hydrade and manganese salt used is two-thirds of the latter to one-third of the former or thereabouts. As soon as the granules refuse to stick together they are dusted over with black oxide of copper, and are then exposed at a red heat to a full current of air until they assume a dark green or black colour. They are then ready for use in the tubes of an apparatus also embraced by this invention, and shown in the annexed illustrations, of which Fig. 1 is a half sectional elevation and Fig. 2 a half sectional plan. Arranged horizontally in the double furnace A are two sets of tubes B B¹, containing the granules above described, and connected at one end to the mains C C¹ communicating through pipes D D¹ with the interior of the hollow plugs of the two-way cocks E E¹. Mains F G for supplying air and steam are connected to the interior of the body of the cocks E E¹. The other ends of B B¹ are similarly connected to two-way cocks H H¹, the interior of the body of said cocks being connected respectively to the nitrogen exit pipe I and the oxygen exit pipe J. This pipe J is connected to the interior of the plug of a tap K, and is also by pipe L connected to the interior of the cooling tank M, from which the oxygen escapes to a suitable reservoir through M¹. The opposite parts of the shell of K are connected by pipes N N¹ to the pipes D D¹. The cocks E E¹, H H¹, and K are connected together and are operated from the pulley O, as shown in Fig. 2. The parts are so arranged that steam is first passed through the

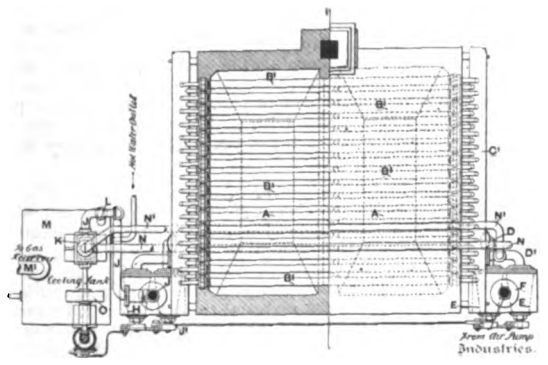

FIG. 2.

retorts, with the result that the material is decomposed into sodium hydrate, manganese, and free oxygen. The oxygen is then conveyed to the gas-holder, being cooled as it passes through M. As soon as all the free oxygen has been given off, the current of steam is replaced by one of atmospheric air. The oxygen of the latter is absorbed by the material, and its nitrogen isolated and allowed to escape. When the absorption of oxygen has ceased the air current is cut off, and that of steam again turned into the retorts to liberate the absorbed oxygen, and so on. The two sets of retorts are so connected to the governing taps that steam is admitted to one set whilst the other is being supplied with air. Seven claims are made.—No. 7851. May 20th, 1890. 11*d.*

AXLE LUBRICATORS.—*H. H. Lake, London.* (*J. A. White, Concord, New Hampshire, U.S.A.*)—Resting on the bottom of an ordinary car axle box is a projection or fulcrum of a curved lever. On that end of this lever which projects beneath the journal is formed a suitable receptacle for holding the felting. The other end of this bent lever projects upwards beyond the end of the journal, and carries a weight which, when the journal oscillates, will rock the lever sufficiently to keep the felting against the underside of said journal. Projections are provided on the bottom of the car axle box to keep the bent lever in place. Claims: (1) A car-axle lubricator provided with a casing or a receptacle for the purpose of containing the felting, and the said receptacle provided with journals on opposite sides adapted to oscillate in the bearings secured to one end of the casing to allow a vertical movement of aforesaid receptacle, and also to allow the felting to keep an equal bearing on the journal; (2) a support having a fulcrum point adapted to rest on the bottom of the box, the aforesaid support supplied with a receptacle of the proper size to hold the felting in contact with the journal, and to take up any wear in the journal or felting as set forth.—No. 20882. December 22nd, 1890. 6*d.*

REVERSING GEAR FOR STEAM ENGINES.—*J. Wild, Oldham, Lancashire.*—Pivoted at some distance from but in about the same horizontal plane as the actuating eccentric is the reversing lever, on that end of which nearest to the eccentric is pivoted a segmental lever, having its lower end connected to and operated from the eccentric by means of a suitable connecting link. Formed in this segmental lever is a slot running the whole length thereof, into which slot projects a pin carried by a slide on the valve spindle. The action of the gear is as follows:—When that end of the reversing lever nearest the eccentric is lowered to its full extent, so that the pin in the slide on the valve spindle projects into the upper end of the slot in the segmental lever, the latter will then act as a lever of the first order. If, however, said segmental lever is raised by the reversing lever, so that the pin of the valve spindle projects into the slot below the point at which the segmental lever is pivoted, said lever will be changed into a lever of the second order, and the motion of the valve spindle will be reversed. Claims: (1) A reversing gear for steam or other motive power engine with a radius or reversing lever, slotted lever, driving rod, and return crank or eccentric as described; (2) a reversing gear in which the backward and forward motions are given by the same agent, and in which the angle of advance for either motion is obtained by moving the driving rod and slotted lever through any angle equal to double the angle of advance.—No. 5878. April 18th, 1890. 6*d.*

RAILWAY AXLE BOXES.—*C. C. Longridge, Conway, Carnarvon, North Wales.*—An axle box embracing the principle of this invention is shown in the annexed illustrations, respectively side and end sectional elevations. The oil box which encloses the axle journal A is provided with a removable cover and is supported at its outer end by means of a flange B resting on the end of A. Resting on the upper periphery of A is the brass bearing block

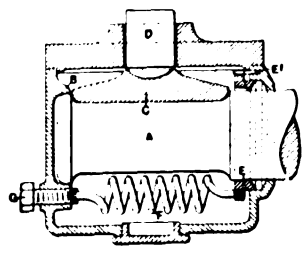

FIG 1

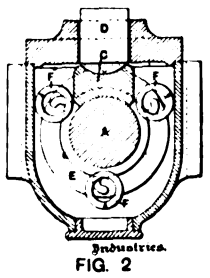

FIG. 2

C which receives the downward pressure of the carrying spring by means of the rod D, the surfaces of C and D forming a spherical joint. To prevent the liquid lubricant escaping around A from the inner end of lubricant box an internal stuffing box gland E, prevented from revolving by means of pin E¹, is forced forward by means of three or more helical springs F, and presses the packing tight around the shoulders of A. The opposite ends of the springs F are held in the ends of set screws G so that the tension of said springs may be varied. The inventor also describes several structural modifications of the above. Five claims are made.—No. 5585. April 12th, 1890. 8*d.*

SELF-ACTING MULES.—*W. E. Dixon, Rumworth, Bolton.*—The invention is intended to dispense with the quadrant, quadrant arm, winding bands, and their appendages, and substitute therefor the following:—On the cylinder shaft is mounted a differential scroll in place of the parallel winding drum at present employed. In fixings attached to the mule carriage is mounted a shaft on which is fixed a second differential scroll, the latter being connected to the scroll on the cylinder shaft by means of a chain. The shaft carrying the second scroll is fitted with a spur wheel gearing with an adjustable rack guided in a box or casing secured to the mule floor. This rack is mounted on a suitable screw spindle, the latter being rotated by means of a ratchet wheel mounted on the end thereof and a pawl mounted on a shaft journaled in a bearing on one side of the guide box. On this shaft is fixed an adjustable lever, against which a projection on the mule carriage strikes at each outward stroke, so as to swivel said shaft, and through the medium of the pawl, ratchet wheel, and screwed rod to automatically alter the position of the second scroll at each outward run of the mule carriage according to the requirements necessary for building the cops. Four claims are made.—No. 4923. March 29th, 1890. 8*d.*

SELF-ACTING MULES.—*W. H. Kershaw, Sowerby Bridge, Yorkshire.*—This invention has reference to the "snarling" motion of self-acting mules, the object of which is to prevent the snarling of the yarn. The object of the inventor is to effect the reversing of the loose half of the ordinary catch or roller clutch box, after it has done its work, preparatory to the next operation. This is done by placing around the loose half of the clutch box a spring clip, the tension of which around the clutch box may be regulated by means of a spiral spring. A finger or arm projects from the spring clip, to which is connected a cord with a weight at one end, so that when the clutches are liberated the weighted cord, acting upon the finger of the spring clip, moves the loose half of the clutch box partially round, ready for the next operation. One or more studs, one of which is adjustable, project from the headstock of the mule, against which the finger of the spring clip acts, so governing the latter's movement. Claims: (1) In the snarling motion of mules the use of a spring clip on the loose clutch box, the tension of which clip is governed by a spiral spring; (2) the use of a spring clip on the loose clutch box operated, when released, by a cord and weight; (3) the use of a spiral clip on the roller clutch box operated, when released, by a deadweight.—No. 6067. April 22nd, 1890. 6*d.*

TYPE DISTRIBUTING MACHINE.—*J. R. Topliss, Melbourne, Victoria, Australia.*—In the annexed illustrations Fig. 1 is a plan, Fig. 2 a front elevation, Fig. 3 an end elevation, and Fig. 4 an enlarged detail of a type distributing machine constructed on the principle of this invention. A is the cabinet formed with vertical channels A¹ (a few only of which are shown), into which the type is to be distributed from a plate B, supported as shown, along which the column of type is carried by means of a pusher C operated by means of a screw D. This screw has on one end of it a ratchet wheel D¹, in which engages a pawl D² (Fig. 3) carried on a lever E, in a slot in which projects

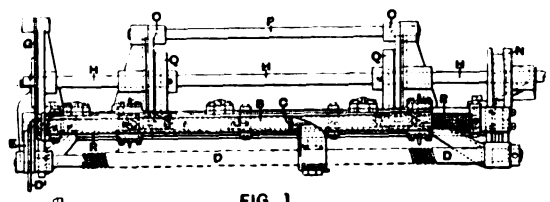

FIG. 1

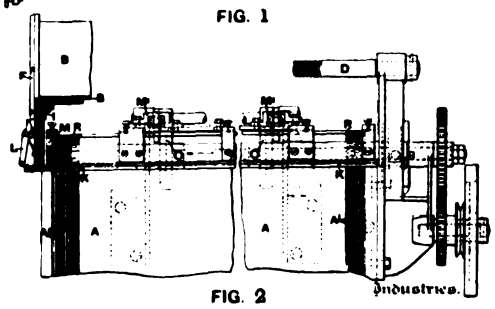

FIG. 2

a roller carried by a slide F sliding in guides F¹. This slide, and consequently the screw D, receives motion by means of a lever G operated by means of a crank on the driving shaft H. The lines of type are fed into a slot I, the rate of supply being governed by a pawl J on the slide F, and are fed forward upon a plate K, with holes corresponding with the channels A¹ by means of a lever L operated as shown by a projection on the lever G. A slide or box M is adapted to be reciprocated horizontally on the plate K by a projection thereon engaging in a cam disc N on the shaft H. This slide is carried by two levers O pivoted on a shaft P, and moved up and down, so raising and lowering M, by means of two cam discs Q. This box M has divisions or slots M¹ formed in it, in which slide the spring pushers R. The action is as follows:—After the type has been fed forward upon K, the box M, being in a raised position, then descends, and is moved forward, so carrying the type with it until it is brought

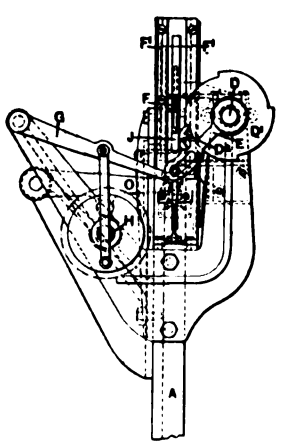

FIG. 3

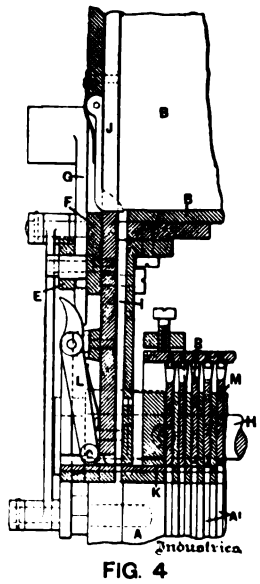

FIG. 4

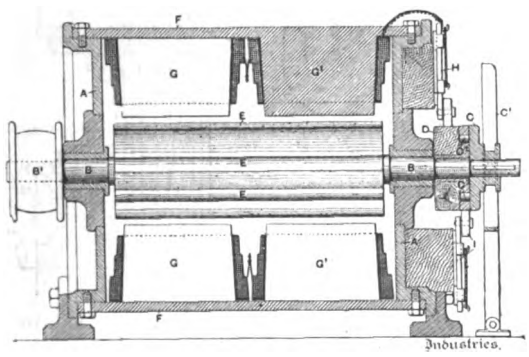
opposite one of the channels A into which it can pass, and into which it is then forced by one of the pushers R. The box M is then raised and carried back to its normal position, and the operation repeated, so that any type remaining on K will be carried forward until falling into one of the channels A¹. Eight claims are made.—No. 4911. March 28th, 1890. 11*d.*

APPARATUS FOR SEPARATING AND DISINTEGRATING FIBRES.—*C. Kellner, Vienna, Austria.*—The apparatus for the above purpose is constructed as follows:—A cylinder formed of segments, bolted together by means of suitable flanges formed thereon, is supported by suitable framework, and has revolving concentrically in it a cylindrical roller, the shaft of which passes through stuffing-boxes in the end plates of the casing and is supported in bearings in suitable brackets, one end of the shafting extending beyond its bearing and carrying the driving pulley. The inner surface of the cylindrical casing and the periphery of the roller are formed with rings of V-shaped teeth, the projecting ends of those of the former projecting into the grooves between those of the latter. An opening is formed at each end of the casing, one in the upper and the other in the lower part thereof, for the supply and the delivery of the fibres. Between the flanges of the segments of the cylindrical casing packing pieces are placed, so that, as the teeth of the parts become blunted, the said parts may be adjusted to one another by reducing the thickness of the packing pieces. Claims: (1) The improved ap-

Digitized by Google

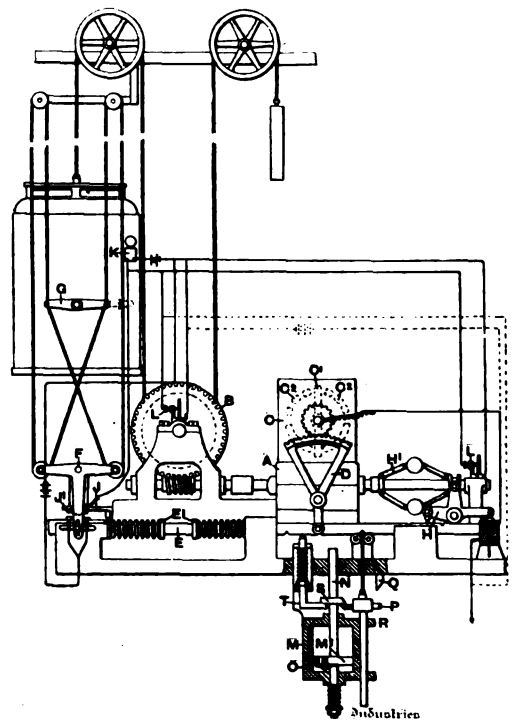


paratus for separating and disintegrating fibres in the manufacture of paper constructed and operated as described; (2) the combination of an externally pyramidal toothed cylinder revolving inside a fixed cylinder constructed of flanged sections similarly toothed internally, substantially as described.—No. 6993. May 6th, 1890. 6d.

APPARATUS FOR CHANNELING WOOD.—*E. Müller, Sorau, Silesia, Germany.*—The apparatus for the above purpose is constructed as follows:—A suitable oblong framework formed of two side bars and two end plates, the latter of which carry suitable clamps for clamping said frame to the board to be operated upon, carries, upon the two side bars, a vertical plate or frame in which slides a flat steel bar carrying on its lower end the cutting tool. This bar has formed on one side of it rack teeth, in which engage the teeth of a small pinion journaled in the vertical frame. The steel bar, and thus the tool, can so be adjusted vertically as desired. One of the side bars of the oblong frame on which the vertical frame is carried is screw-threaded, and may be revolved by means of a suitable hand-wheel fixed in the end thereof. The hole in the vertical frame through which this screwed bar passes is also screwed, so that the vertical frame, and thus the steel bar and tool, may be adjusted horizontally. The operation is as follows:—A hole is first bored in the wood to be operated upon; the operating tool is then adjusted horizontally so that when forced down it will shave the side of said hole, thus elongating it. The chisel is then raised and advanced horizontally, so that when again forced down it further enlarges the hole, and so onward until a groove of the desired length has been made. For the purpose of adjusting the depth of cut of the chisel an adjustable ring is placed on the rack bar, which ring is adapted to strike a projection on the vertical frame. Claims: The apparatus for cutting grooves in wood as described.—No. 4147. March 17th, 1890. 6d.

ELECTRICITY.

SAFETY DEVICE FOR ELECTRIC CIRCUITS.—*W. Lowrie & C. J. Hall, both of London.*—The safety device embraced by this invention has for its object the prevention of a dangerous electrical pressure existing latent in any circuit by providing an outlet to earth should a given limit be exceeded. For this purpose a pair of spring conductors, placed within a closed vessel containing rarified gas, are used, which conductors tend to make contact with one another, but are prevented from so doing by means of a suitable material placed between them, which however, becomes carbonised when the electrical pressure exceeds a given limit. One of these spring conductors is permanently connected to earth, and the other to the circuit to be protected. An indicator to show when the connection to earth has been closed may be combined with said safety device. Five claims are made.—No. 6475. April 28th, 1890. 8d.



ELECTROMOTORS.—*G. R. Postlethwaite, Aston, near Birmingham.*—A motor embracing the principal features of this invention is shown in the annexed illustration, representing a sectional elevation. Journaled in the end plates A of the framework of the motor is the armature shaft B with driving pulley B^1. On the opposite end of B to B^1 is a clutch C fixed by means of a feather, so that it can be moved longitudinally along B by means of a lever C^1, but revolves therewith. This clutch is adapted by studs C^2 to engage holes in the metallic facing on the commutator D mounted loosely on B. The armature E is in cross section of cross shape. The field magnets are connected to a circular casing F, and are formed with web-shaped cores G G^1, the winding of the opposite parts G G^1 being connected in series so as to practically form one electromagnet. There are twelve such magnets divided into four series and connected to three positive

brushes H in the following manner:—Supposing these magnets to be numbered from 1 to 12, the positive wires of 1, 2, and 8 are connected together so as to form one terminal. The negative wire of 1 is then connected to the positive of 4, the negative of 4 to the positive of 7, and the negative of 7 to the positive of 10. The wires of 2 are similarly connected to those of 5, 8, and 10, and those of 3 to those of 6, 9, and 12. The negative ends of the coils 10, 11, and 12 are connected to the slides or brushes H. These brushes are adapted to press upon the commutator D, which has four metal straps connected electrically to its metallic facing, upon the edge of which facing presses the negative brush I. Nine claims are made.—No. 2337. February 13th, 1890. 8d.

FLASH SIGNALLING LANTERNS.—*W. S. Rawson, London, & C. S. Snell, Culver Park, Saltash, Cornwall.*—Arranged in a suitable cylindrical casing one above the other are two solenoids, the common core of which carries upon its upper end the extinguishing shutter of the lamp, said lamp being fixed above the axis of the cylindrical casing in a suitable lantern casing. The uppermost solenoid is wound with coarse wire, and the lower one with fine wire, and the former is arranged so that, when the light is obscured, it is in circuit with the lamp, and reduces its intensity, whilst the latter solenoid is arranged to work in a shunt to the lamp, and it is this solenoid which pulls down the shutter against the action of suitable springs. A suitable switch is provided for regulating the current through the solenoids, said switch being so arranged that the two solenoids shall be momentarily in action simultaneously, so as to prevent sparking. In a modification, several shutters are used. Claims: (1) In an electric signal flashing lamp, the employment of two concentric solenoids which have a common core and actuate a shutter as set forth; (2) the employment of springs acting in opposition to one another and in combination with the core; (3) the arrangement of the circuits as described; (4) a method by which the colour of the shutter used can be altered; (5) the combination and arrangements of the parts of a lantern and operating switches as described.—No. 3937. March 18th, 1890. 8d.

ELEVATORS.—*The American Elevator Company, London. (Otis Bros. & Co., New York, U.S.A.)*—In the annexed illustration is shown a view of the operating mechanism of an elevator such as embraced by this invention. The motor A, of any suitable description, actuates by means of a worm the wheel B around which the cable for raising or lowering the elevator cage

passes. The actuating current of said motor is regulated by means of a resistance device C provided with a switch C^1, so connected with the conductors and arranged in respect to the resistance terminals C^2, and connected with the armature winding, that the movement of the switch from its mid-position to one side will close the circuit through the resistance, and will gradually cut out the resistance and impart motion to the armature in one direction, while the movement to the other side will gradually cut out the resistance and impart movement to the armature in the other direction. The switch is actuated by means of a a gear wheel on the shaft thereof and the tooth sector D, an arm on which is hinged to a rod E, normally held in the position shown by springs E^1. This rod receives motion through the medium of a lever F and ropes, as shown, from the lever G in the car. When the switch is moved in either direction as far as possible it will be so held by means of a lever H, a catch on one end of which engages in V notches in E. It will, however, be released by means of the governor H^1 should the speed of the motor fall; and should the tension of the supply current become too great it will also be released by an electromagnet I in the supply circuit. On a bracket J is a contact J^1, which, when E is moved in either direction, makes contact with one of two contacts on the end of E, so completing a circuit through the bell K in the car. Circuits connected with thermostats L on all the bearings also include K, so that, should the bearings become heated, an alarm will be sounded. In order to return E to its normal position after a certain length of time, an arrangement is used consisting of a dash-pot cylinder M, piston M^1, piston rod N, and circulating channel O. The motion of E either way from the centre lifts the piston, until the bolt P is pushed back by the inclined cam Q by the pin R on the bolt travelling on the inclined face of the cam. The piston returns now to its bottom position and the toe S in its down path strikes the detent bolt T and releases E, which then returns to the centre and opens the circuit, shutting off the current. Twelve claims are made.—No. 624. January 13th, 1891. 8d.

METHOD OF CONNECTING CONDUCTORS.—*J. Marx, Sachsenhausen, Frankfurt-on-Maine, Germany.*—According to this invention the ends of the wires to be connected are connected electrically with two circular or other shaped plates, which are then placed opposite one another, and at a suitable distance apart, in a cylindrical box or container. The opposite faces of the plates are provided with projections. When in this position a mixture consisting of a good conducting material, such as powdered carbon or graphite, and a conglomerating material, such as paraffin wax, is run into the box between the plates. When this mixture has cooled, the box or container which has acted as a mould is removed, and the joint is then complete. Claims: (1) A safety device for electric circuits consisting of a mixture of a conductive material with a material which softens or fuses when undue heating of the conductors occurs, the said mixture being placed in the circuit as described; (2) the interposition in an electric circuit of a mixture of powdered carbon or graphite and paraffin wax, stearine, pitch, resin, or the like; (3) a safety device as described, contained in a frame or box, and having the conductors connected therewith; (4) a safety device for electric circuits as described.—No. 6267. April 24th, 1890. 8d.

ARMATURES FOR DYNAMOS AND MOTORS.—*R. E. B. Crompton, Chelmsford, Essex. (W. Fritsche, Berlin, Germany).*—The invention relates more particularly to armatures of the disc or wheel form, which are constructed according to this patent in the following manner:—Fixed on the armature shaft are two hubs, between which are firmly held the ends of a number of radially placed spokes or staves of soft iron, having on their outer ends abutting segments such that when arranged in correct order they form a complete wheel. These staves can be connected electrically so as to form the required electrical armature circuits at points inside and outside the ring of field magnets by curved segments or connectors. The staves are made so that each alternate one is of greater length than the others. These longer staves are connected to properly formed segments which in some cases may form the commutator of the dynamo. In the upper and lower parts of the staves are formed notches by means of which the connectors may be attached to them, said connectors forming two concentric rings of connection. Claims: (1) A wheel armature composed of any number of parts of iron staves placed by the side of each other in one plane, only one stave of each pair having at one end or its side a collector segment, which construction, subject to a connection of the staves as described, forms at the same time the core of the collector, the support, and the winding of the armature; (2) the manufacture and use of armatures for dynamo electric machines and electric motors arranged and operated substantially as described.—No. 5750. April 16th, 1890. 8d.

CHEMISTRY.

APPARATUS FOR CONCENTRATING SULPHURIC ACID.—*C. S. Négrier, Périgueux, France.*—The apparatus for the above purpose is constructed as follows:—The space above the usual range of hearths is partitioned off, the partition being on an inclined plane. This partition consists of a number of iron plates formed each with a number of hemispherical depressions, and placed together and supported on suitable walls. These cavities are provided with small holes in their lower parts, plugged with clay to preserve the plates. Placed in each cavity (of which there are preferably four in each plate) are vessels of porcelain or other non-corrodible material, each having a lip projecting over the next below in series on the inclined plane. The sulphuric acid is passed into the uppermost vessels and trickles over into the next lower ones, and so on through the series, until it overflows from the last, in a more or less concentrated state, into a suitable duct, by means of which it is carried to the concentrated chamber proper, which latter is constructed with an inclined plane and vessels on a similar system. The acid, after suitable concentration, is carried into a leaden receiver, where it is cooled. The vapours arising from the acid are carried into a leaden vessel, and from thence into a second leaden vessel, in which they are cooled, and from which they then pass to the main lead chamber. Claims: (1) The method of concentrating sulphuric acid by passing the acid through a series of basins over the producing furnace previous to its treatment in the concentrating furnace proper; (2) the apparatus consisting of plates with hollows and basins therein arranged in the furnaces in the manner and for the purpose set forth; (3) the method and apparatus for carrying the acid vapours and steam which are products of the concentration of the acid from the spaces above the condensing vessels into the lead chamber as described.—No. 4171. March 17th, 1890. 8d.

MISCELLANEOUS.

PIPE WRENCHES.—*E. S. Hunter, North Shields.*—Pivoted on each side of the end of a suitable steel lever are a pair of long curved steel links, between the upper ends of which is pivoted a T piece, to which are connected the two end links of a chain, composed of a series of shorter curved alternate single and double steel links. The upper end of the main lever or handle on each side of which the long curved links are pivoted is rounded and serrated crosswise, as are the edges of the links on one side of the chain near the free end thereof. The gripping action is as follows:—The chain is bent round the pipe to be gripped, and the remaining end passes between the long curved levers. In this position that side of the links which is serrated is on the opposite side to the pipe, and the serrations on the end of the chain engage with those on the end of the handle lever when the latter is moved in the opposite direction to that in which the chain is wound around the pipe. Claims: (1) The long and short curved links with and without teeth; (2) the flat circular toothed end of lever.—No. 1401. January 26th, 1891. 6d.

DRYING MACHINES.—*J. F. Johnson, Belvedere, Kent.*—The invention relates to drying machines suitable for refuse and other such like matters, and consists of a number of semi-cylindrical troughs placed end to end and in steps, each trough being below the preceding one. Each trough has journaled in its ends a shaft driven from overhead shafting, and carrying suitable scraping blades, by which the material to be dried is led forward along the trough until it comes to the end thereof, when it drops into the next trough. These troughs are supported in the flue of a single furnace, and are heated therefrom by means of water-jackets surrounding them, so preventing undue heating by the furnace. Each trough is provided with a semi-cylindrical cover. This cover, at the feed end of the trough, is connected by a pipe to an exhaust fan, whilst at the other end of the trough is formed a hole to admit the products of combustion from the flue into the interior of the trough. Claims: (1) Drying machines, in which there are a number of troughs communicating with each other, each trough having within it a shaft supported at its ends only, and carrying scrapers as described; (2) drying machines, substantially as described.—No. 3383. March 3rd, 1890. 6d.

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10d. *or fraction of* 10d. *Remittances exceeding one shilling must be made by Post Office Order.*

BOILER CONSTRUCTION.*

INTRODUCTION.—I have the honour to invite your attention this evening to the construction of boilers adapted to forced draught, and, as the subject is obviously far too extensive to deal with at one meeting, I propose to confine this paper almost exclusively to the study of that branch of it which lately has given so much trouble—viz. leaky tubes. Our inquiry will be directed towards ascertaining what causes such leakages, this being the first step towards finding a remedy. Let us first consider a few matters of detail, which deserve far more attention than they generally receive.

WORKMANSHIP.—A certain amount of trouble must be attributed to insufficiently good workmanship and materials; for it must be borne in mind that, with forced draught and higher pressures, boilers are far more severely strained than formerly, consequently workmanship which was good enough but a few years ago is now quite unsuitable.

QUALITY AND CONDITION OF TUBES.—First, with regard to the quality of the tubes. The best that are procurable are none too good. Good tubes are of the most ductile material and carefully annealed at the ends, and will stand flattening and bending over without cracking, such as the samples which I have here. They should be perfectly straight, or if curved, as sometimes done, they should be all curved alike, so as to maintain the same water space throughout their entire length and secure a uniform elasticity. This elasticity will enable all the tubes to take an equal share of the strain thrown on them. The thickness of the tube at the part where it is expanded must be the same all round; this it frequently is not; and there should be no ridges inside caused by the weld, otherwise the expander meets with inequalities, leading to irregularity in the work. The outside of the tube where it passes through the tube plate must be free from scale or oxide, and should be bright, so that when expanded the metal of the tube should come in close contact with the metal of the plate. Tubes polished at the ends as supplied by the makers are generally well greased to protect them from rust. This grease, as well as the oil remaining in the holes of the tube plate after having been drilled, must be completely removed; if this is not done, there will remain in places a film of grease between the two surfaces, after the tube has been expanded.

METHOD OF EXPANDING TUBES.—The usual method of expanding is to bore parallel holes in the tube plate, and expand the tube with an expander, which will give a taper. Now, in no other part of the machinery should we think of putting a taper pin into a parallel hole. If the hole is parallel, an expander should be used, which will expand the tube so that it also becomes parallel, or, if a taper expander be adopted, then the hole in the tube plate should be bored to correspond, so as to ensure the perfect bearing of the tube throughout the entire

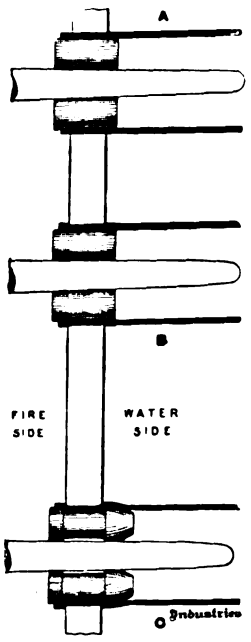

FIG. 1.

thickness of the plate. Unless one of these courses is adopted we get a bearing of the tube in the plate which will vary according to the inclination of the workman; no two tubes will be expanded equally, and the expanding will be carried out to an unknown and irregular extent. As an illustration of this, I have here a tube which has been expanded into a plate in a manner frequently met with (see A, Fig. 1). On the one side, as anyone closely examining it will see, the tube and plate do not touch. This is partly due to adopting a taper expander in a parallel hole, and partly to the rollers not going sufficiently far through (see B, Fig. 1). Special care should be taken that the rollers of the expander pass well through the plate, so as to swell out the tube, not only throughout the thickness of the plate itself, but a little beyond, ensuring thereby that the tube is in close contact with the plate throughout its thickness, and a slight swelling of the tube on the inside, forming, as it were, a small shoulder, and thereby preventing the tube from shifting in the hole when a compressive strain comes on it. This in actual practice is often neglected, the relative position of the rollers to the tube plate being left to the workman. In passing, I would allude to an expander C (Fig. 1) we use frequently. In it the rollers are

* Paper read by Mr. A. F. Yarrow before the Institution of Naval Architects, March 19th, 1891, and fully entitled "Boiler Construction Suitable for Withstanding the Strains of Forced Draught, so Far as it Affects the Leakage of Boiler Tubes."

BOILER CONSTRUCTION.

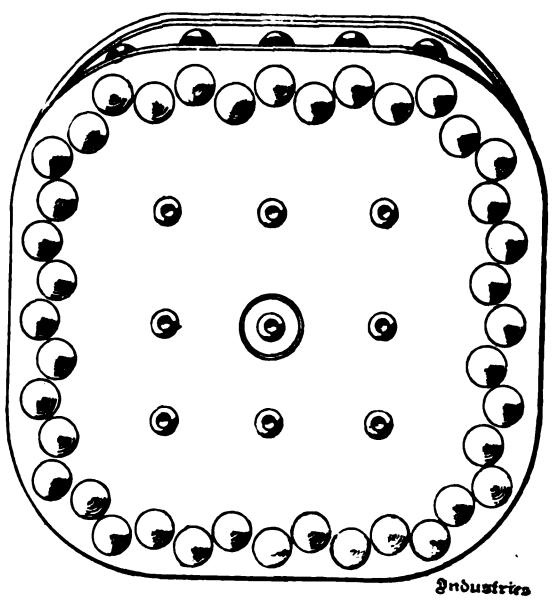

FIG. 6.

parallel for a length a trifle greater than the thickness of the plate, and are then slightly increased in diameter, thus ensuring pressure coming on the tube throughout the thickness of the plate, and raising a very defined shoulder on the tube both inside and out. In this way a very firm job is secured, and the tube is prevented from being either pushed or pulled through the plate. This bead on the tube at the inner side of the plate is very desirable. On the London and North-Western Railway at Crewe a tool is adopted which is specially designed for producing this bead, and also at the Baldwin Locomotive Works, Philadelphia, and many locomotive superintendents do practically the same thing by reducing the diameter of the tube where it passes through the tube plate, thus forming a shoulder against which the tube is driven up. Assuming we have a proper expander, let us now deal with the way the expanding is carried out. The custom is for the boiler-maker to settle himself down comfortably inside the box, and work away at one side or at one corner, expanding a large number of tubes, and then shifting his position. This is objectionable, because by expanding a great many tubes in one place a considerable strain is thrown on the plate, which is stretched, and in this way severe local strains set up. The better plan is to expand three or four tubes in one locality and then shift to another, expanding all over as gradually and uniformly as possible. Some people advocate screwing the tubes into the tube plate, and expect by that means to make them tight. We have done this, and abandoned it, as it does not deal with the root of the evil; moreover, it presents practical difficulties, especially when the time comes to retube the boiler. Sometimes a thin copper sleeve, or ferrule, is put over the end of an iron or steel tube and expanded with it into the plate. This frequently reduces the leakage of tubes. The explanation may, perhaps, be found in the fact that, with a rise of temperature, the copper increases to a greater extent than the surrounding material, and tends to fill up any gap which may occur.

STAY TUBES.—With regard to stay tubes, for many years we have not used them, and have found no injurious result. On the contrary, I believe, so far as the leakage of tubes is concerned, they are bad. In the first place, they are invariably thicker than the surrounding ones, and to have rigid tubes alongside those which are elastic is clearly undesirable. If stay tubes must be adopted they should be equally elastic with the others, and consequently of the same thickness and same material, only thickened up where they screw into the plates.

HOLDING POWER OF ORDINARY TUBES.—Some years ago we carried out a number of experiments with a view to ascertain the power required to withdraw from tube plates tubes expanding in the usual way. We found that a 2in. tube had a holding power in a steel plate of from 8 to 12 tons; and a number of specimens from these tests are here. In a fire-box, as shown in Fig. 2, at a pressure of 200lb., we have a total stress separating the two tube plates of 124 tons. Now the total holding power of the tubes to withstand such pressure, based upon 8 tons per tube, is 2,300 tons, giving a margin of security of nearly 20. It is for everyone to use his own judgment in the matter of adopting stay tubes or not. With very few exceptions locomotive engineers in this country and America are adverse to them.

FERRULES.—Concerning the use of ferrules, their adoption does not seem to affect the leaky tube question to any material

BOILER CONSTRUCTION.

TABLE I.—Experiments to Ascertain the Strength of Water-space Stays.

Description.	Length between Plates.	Diameter of Stay over Threads.	Ultimate Stress.
Hollow stays screwed into plates and hole expanded	4·75in. 4·64in.	1in. (hole $\frac{7}{16}$in. and $\frac{5}{16}$in.) 1in. (hole $\frac{9}{16}$in. and $\frac{7}{16}$in.)	25,457lb. 20,992lb.
Solid stays screwed into plates and riveted over	4·80in. 4·80in.	$\frac{7}{8}$in. $\frac{7}{8}$in.	22,008lb. 22,070lb.

The above are taken as a fair average of numerous tests.

TABLE II.—Expansion of Copper Tubes and Outside Shell when Raising Steam.

Lit up at 10.20 a.m.; 4in. over fire-box.

Time	10·30	10·40	10·50	11·0	11·10	11·20	11·30	11·40	11·50
Steam	0	0	0	0	lb. 0–5	lb. 20–10	lb. 60–80	lb. 100–120	lb. 140–160
Elongation of barrel in m/m. Length measured, 3ft. 4½in. = 1,028 m/m.									
Boiler shell at water level	·2	·6	·8	·9	1·4	2 0	2·5	2·7	2·8
Top	0	0	0	·4	1·6	2·0	2·5	2·5	2·8
Bottom	·2	·3	·4	·8	1·6	1·6	2·5	2·5	2·5
Elongation of tubes in m/m. Length of tube, 3ft. 10in. = 1,168 m/m.									
Top tube	1·5	1·6	1·6	1·6	2·5	2·7	2·9	3·8	4·0
Bottom tube	·7	·9	1·5	1·4	2·0	2·5	2·9	3·6	3·6

extent. If the tubes leak without ferrules we have no reason, based on experience, to believe the ferrules will cure it. They do not strike at the root of the evil. They may be used with advantage for those tubes which are subject to the fiercest fire, as they interpose a resistance to the rush of flame by reducing the area, and thus cause the heated products of combustion to pass more uniformly through all the tubes. Although I occasionally refer to locomotive practice, I would point out to those not familiar with the subject, that an ordinary locomotive boiler is not applicable to marine purposes without considerable modification: water that has passed repeatedly through a surface condenser requires very different treatment to water such as is used on our railways, therefore the ordinary locomotive boiler must only to a limited extent be taken as a guide in the present investigation.

Water Space Stays.—With regard to the water space stays uniting the inside and outside fire-boxes, too much care cannot be exercised in arranging these with a view to secure for the inside fire-box the necessary freedom of movement due to the variations in temperature. In the year 1878 we built a torpedo boat for a foreign Government, and had no less than eight unsuccessful trials, in every case coming home with the tubes leaking (Fig. 3). To ascertain exactly what was going on in the region of the tube plate, we removed the row of stays nearest to the tube plate flange, on the sides and top of the box. We replaced these stays by others working in stuffing boxes and having a nut on the outside, so that if a tensile strain had to be met they were there to receive it, while if the inside box wanted to expand it had freedom to do so. This experiment was most interesting; every time the fire was urged these stays would all move outward through their stuffing boxes, owing to the expansion of the box. In some cases the movement was sufficient to enable a penny piece to be inserted between the nut on the stay and the gland. Each time the fire-door was opened and the temperature reduced these stays would move inward, and when the boiler was cool the nuts pressed hard on the glands. From the moment the new stays were fitted the boiler was altogether free from leaky tubes, and the boat was duly taken over by the Government. It is, of course, dangerous to draw a conclusion from one isolated experiment; at the same time, it seems more than probable that these stays, as originally fitted, had much to do with the leaking of the tubes, because it is evident that a tensile strain coming on a tube plate weakened by being perforated with a number of holes, is likely to distort the plate. As a matter of fact, prior to the new stays being fitted, this tube plate was more or less altered in shape after every trial. Fig. 4 shows exactly the change that took place on the first trial alone. It will be seen that between the points indicated on the diagram there was in one case an extension of ½in., and in the other an extension of ⅝in. I think we may assume that tube plates should be free from external strains, and, as far as possible, be allowed freedom to move as the changes of temperature require. With a view to carry this out we make a practice of having the first row of stays at least 7in. from the edge of the tube plate flange, and even these stays in large boilers are so designed as to be free to move.

Elasticity.—It will be seen, by reference to the section of the boiler (Fig. 2), that the greatest possible elasticity is allowed for throughout. Special care should be taken that the flange of the tube plate is made very thin, so as to secure elasticity and avoid the possibility of strains being thrown on the tube plate itself where the tubes pass through, also to avoid a large difference of temperature between the inside and outside of the double thickness. To ensure freedom for movement, the water space should not be cramped, otherwise trouble will be met with by the leaking and breaking of the stays. In order to gain elasticity, we follow the plan frequently adopted in locomotives, of turning the stays down between the plates. This ensures any bending of the stays being confined to the portion within the water space, and prevents movement of the stay in the plate itself, thereby causing leakage.

Hollow Stay.—Perhaps I may be permitted to draw your attention to a stay we occasionally use. It has been designed to meet a condition frequently occurring when several locomotive boilers are placed closed together, and in consequence, the stays at the sides are inaccessible for repair or renewal. It is shown in Fig. 5, and is a modification of what is adopted by Mr. Park, of the North London Railway. In his case, holes are drilled a short distance into both ends of the stay, into which a drift is forced; the stay is thus swelled out until it fits tightly into the plate, thus making a thorough mechanical job, and probably sounder work than if the stay were riveted over as usual. In the case of a locomotive, as both ends of the stay are accessible, the drift can be used at both sides. As will be seen, the new stay has been designed so as to be made tight at both ends, working from one side only. In an inch stay we drill a ½in. hole nearly all the way through, and then a ⅜in. hole for the remainder. The stay is screwed in from the inside of the fire-box, and a taper drift is passed through the larger portion of the hole and driven into the smaller, swelling the stay out and making it a tight fit at that end. A larger drift is then used for swelling out the end next the workman. By this means a stay can be put in or repaired, making it tight at both ends, the entire operation being performed from one side only. Mr. W. H. Maw has proposed to increase the diameter of the drift at the extreme end. This seems a decided improvement, as it causes the hole to be swelled out parallel, and also enables the drift to be more readily withdrawn. An inch stay with a ½in. hole gives the same strength as a ⅞in. solid stay. The exact stresses which both these stays can resist have been carefully tested, and the results are as shown in Table I. We have also here a water space (see Fig. 6) having 1in. hollow stays, 4in. centres. This, when tested by hydraulic pressure, gave way at 1,650lb. per square inch.

Tube Spaces.—The distance between the tubes should be determined with a view to ensure an ample supply of water to the hot surfaces, and to avoid the steam being imprisoned between the tubes, especially in the region of the tube plate, so that the heat should be carried away as soon as it arrives at the interior surface. Certainly nothing less than ¼in., or perhaps, better still, 1in. space should be adopted with 2in. tubes, when burning, say, 80lb. to 100lb. of coal per square foot of fire grate per hour. This space will give ample room for good circulation, provided the latter is not restricted or interfered with by any features in the design. Of late a number of unsuccessful marine locomotive boilers have been constructed with water bottoms. It may be a matter worthy of consideration whether the powerful

Digitized by Google

upward current throughout the water space round the fire-box is not the means of drawing from the lower part of the barrel a large quantity of water, thereby robbing the tube plate of a portion of the supply which it would obtain if there were no water bottom.

Length of Tubes.—The length of the tubes should be of such proportion to their diameter as will ensure the necessary elasticity. For this reason, large tubes or short ones are objectionable, as they are too rigid.

Alteration of Tubes when Raising Steam.—In reference to this portion of the subject, I will refer to a very interesting experiment we carried out with a view to ascertain exactly what was happening to the tubes during the process of raising steam, and also when at work. I would call your attention to Fig. 7. (It should be understood that, in many cases, the diagrams referred to in this paper are exaggerated, so as to illustrate the reasoning more plainly). It will be seen that, through three of the tubes, which are at different levels, there are fitted three bars; the latter are fixed at the end next the fire, and also in the centre of the tube. The object of this experiment was to ascertain if the tubes remained straight, and, if not, to register the extent of the bending, which could be made apparent by the alteration in the position of the extreme ends of the rods. Almost immediately after lighting up, it was found that the top row of tubes was evidently heated in advance of the rest. The hotter water, as might have been expected, was near the surface; the cold water at the bottom remained undisturbed, and the top of the boiler was also cold, owing to there being no steam to heat it. The water near the surface, being raised in temperature, those tubes which passed through it strove to increase in length, but, owing to the tube plates being fixed, they were unable to do so, consequently there was a considerable bending of the tubes. This was made evident by the movement of the end of the rod. After the fire had been alight about ten minutes, the second bar began to move as the water at the lower level rose in temperature. In like manner, after a further interval, the third bar moved; and the bars all continued to move until such time as steam began to rise. As soon as 10lb. or 15lb. were registered, the pressure on the tube plates began, apparently, to make itself felt and forced them apart, throwing a tension on the tubes which straightened them. From thence up to 160lb. the tubes showed practically no curvature. This experiment proves how necessary it is to provide ample elasticity in the tubes, so as to comform to the conditions which have to be complied with in raising steam.

Distortion of Boiler while Raising Steam.—The strains which boilers have to withstand when lighting up are well known to be very serious and of an entirely different character, and in some parts far more severe than those met with when at full work. As evidence of the strains caused by unequal expansion when lighting up I would refer you to Figs. 8 and 9, and Table II. Table II. shows the longitudinal expansion of the boiler barrel at different parts and at varying periods during raising steam; Fig. 9 illustrates the movement of the inside box, and Fig. 8 shows the changes of length in another example. These examples illustrate that the distortion of form in some parts is greater during this process than when steam has been raised. With a view to reduce these strains and increase the temperature of the boiler as uniformly throughout as possible when raising steam, we make a practice, in the case of a large boiler, of filling it quite full, and, as the temperature rises, allowing the water to run out from the blow-off cock, so that by the time steam shows itself the water is at the working level. In this way the upper part of the boiler is warmed up, and the cold water at the bottom is got rid of. It is reasonable to suppose many boiler troubles might be avoided if this or some similar plan were adopted. In cooling down the strains are not so great, and are quite different in character from those met with in lighting up. One main principle must be borne in mind, that any changes of temperature should take place as slowly as possible. The sudden putting out of the fire is therefore bad, and may cause tubes to leak. This would not occur if the fire were allowed to burn out very gradually, as it ought; a fact which every locomotive driver knows perfectly well. The annealing of the tube plate, if of iron or steel, should be effected with exceptional care, so as to reduce changes of form when the boiler is first set to work. This annealing should of course be done when the plate is flanged, and possibly it might be desirable to do it after the tube holes are drilled, leaving a trifle to be rimered out finally.

Air Pressure.—I would here say a few words with reference to the amount of air pressure. In the passage of the air from the stoke-hold to the funnel, the greater part of the resistance to be overcome in most cases is due to forcing the air through the tubes; consequently, if a contractor be limited to a given amount of air pressure, the only means he has open to meet this condition without extra weight is by augmenting the diameter of the tubes, or reducing their length, thus producing rigidity, which I have already pointed out is bad. Because a certain boiler does not stand a given air pressure without the tubes leaking only proves that that air pressure is too much for that boiler, but does not prove that this air pressure is too much for every boiler, especially in face of the fact that locomotive engines are working all over the world at air pressures varying from 3in. to 8in. I would call attention to Fig. 10, showing the vacuum in the smoke-box of a Midland engine. This has been kindly given to me by Mr. Johnson. In confirmation of the high air pressure used on locomotives, I cannot do better than quote the following statement of a locomotive engineer of one of our leading lines:—"We do not consider from our experiments that a vacuum of 8in. in a smoke-box is anything exceptional, but should expect it when working full power, either going up a bank or drawing a heavy train on a level. In addition to the vacuum in the smoke-box we register a pressure of air in front of the ash-pan, due to the speed of the train, of 2in. of water, making a total air pressure of 10in." With these facts before us there ought to be no condition imposed upon the marine engineer limiting the air pressure. Would it not be good policy to leave the hands of the designer and maker free to adopt whatever air pressure he likes so long as he gives security that the boiler he supplies will stand it? It is surely better to adopt a high air pressure and have a reliable boiler rather than limit the air pressure and have a boiler which at any unexpected moment may give way altogether; in other words, a low air pressure involves a rigid boiler, and a rigid boiler is not reliable. I think we may fairly conclude that by limiting the air pressure the very best possible inducement is held out to supply a bad boiler, because it leads to a rigid one. If it be wished to limit the temperature of the furnace, which I am ready to admit is desirable, I submit that this may be better effected by limiting the rate of combustion, and when it is ascertained what air pressure corresponds to such rate of combustion, a correct limit of air pressure can be determined for that particular boiler.

BOILER CONSTRUCTION.

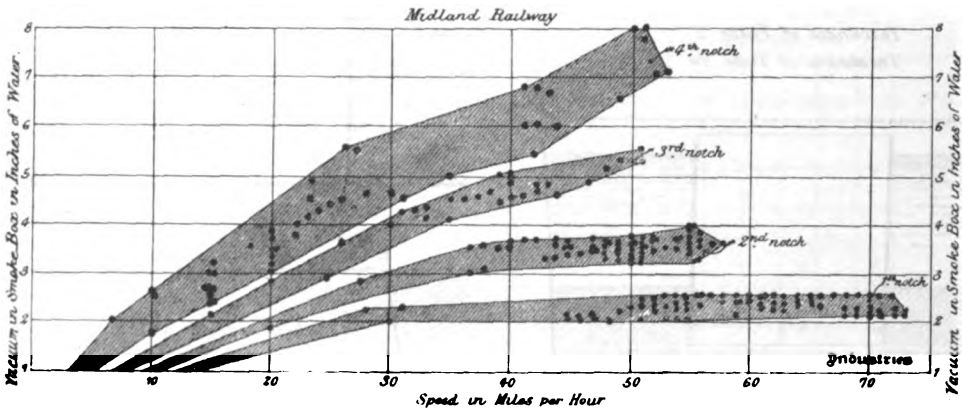

Fig. 10.

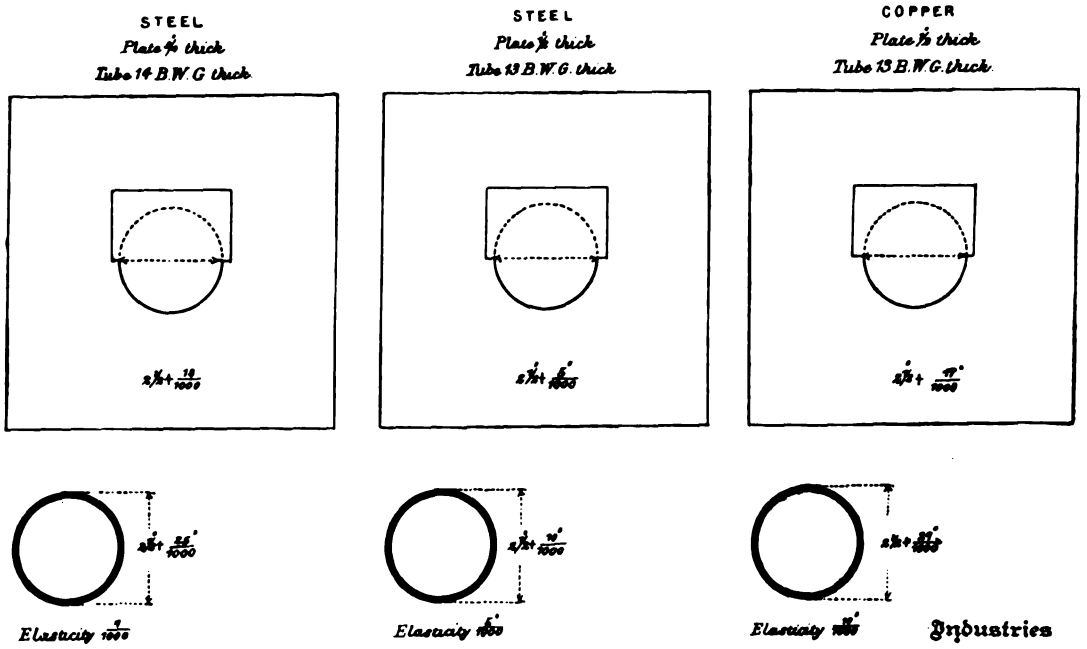

Fig. 11.

Grease.—I need not dwell upon the importance of avoiding grease gaining access to the interior of boilers, as this is well known.

Starting New Boilers.—The bringing into use of new boilers should take place gradually. An ordinary brick furnace when new is heated up very slowly, otherwise it cracks and falls to pieces. Were the same consideration extended to a steam boiler it would often avoid trouble by allowing the various parts to accommodate themselves to their new condition by slow degrees. Many trials have failed through over-anxiety to work up boilers to their full power too quickly. Boilers when new, however, frequently give more or less trouble from leaky tubes at the commencement of the trials. To this we do not attach importance, provided it is due to unavoidable changes of form, which are temporary. It need not be looked upon as of serious moment, as the leakage will soon disappear. Very frequently the tubes leak on cooling down, and, if this happen only to a small extent, it deserves little attention and is of everyday occurrence. Probably the best thing to be done is to leave the tubes alone. Often people take fright at this small leakage and start re-expanding, unnecessarily punishing the tubes. In the foregoing remarks I have simply drawn your attention to a few practical points which deserve consideration. There are many others which time will not admit of our dealing with, such as the position of the air inlet, the position and description of the fire door, the thickness of the fire, and the best mode of stoking. These should be determined, as far as possible, with a view to reduce variations in the temperature of the furnace and avoid cold air coming in contact with the tube plate. There are many other points of importance which we must also pass by.

Elasticity of Tube in Tube Plate.—Now let us study exactly what takes place in expanding a tube into a tube plate. The tube is increased in diameter and pressed against the sides of the hole in the plate, the pressure slightly increasing that hole. The two metals are not only in contact, but are actually pressing against one another. The tube, if it were free, would become slightly larger; and the hole, if it were free, would become slightly smaller. We know this from direct experiment (see Fig. 11). I have here some 2½in. tubes which have been expanded into plates, and then the plates have been cut in the manner shown, so as to enable the tubes to be removed without disturbing anything. On carefully measuring the diameters, both of the tubes and the holes, a very appreciable difference is found, and it is this difference which is to help us in keeping the tubes tight. The actual collective elasticity of the tube to expand and the plate to contract amounts, with steel tubes and tube plates, in one case to $\frac{7}{1000}$in., and in another to $\frac{6}{1000}$in., and $\frac{18}{1000}$in. in the case of copper tubes and tube plates. Assuming that a tube is well expanded, it will remain tight in the plate so long as nothing takes place—such as a sudden reduction of temperature—to cause the tube to be reduced to a greater extent than the collective elasticity of the tube plate and the tube. Now, when steaming hard, if the fire door be opened, and a blast of cold air admitted, the tubes through which it passes, being thin, will feel the effect and contract before the thick tube plate. The tubes will remain tight only so long as the chilling does not tend to reduce the diameter of the tube beyond the collective elasticity of the tube and the plate. Should this elasticity not be sufficient to make up for the change of form, the tube will leak. If the tube plate be thin, so that the rate of its contraction approaches that of the tube, difficulty from this cause will be reduced. Anything that can be done to increase the range of elasticity of the tube and tube plate, allowing thereby larger differences of temperature, is clearly desirable. One simple way in which this can possibly be augmented is by making the tubes a driving fit into the plate, and not simply slipping them loosely into the holes, leaving the expander to do all the work. Mr. Park, of the North London Railway, attaches great importance to making the tubes a very tight fit in the holes.

Thin Tube and Thick Tube Plate.—To ascertain the effect of heating and cooling tubes in a tube plate, we have tried some experiments, the results of which are shown on Fig. 12. We have here a $6\frac{7}{16}$in. tube, $\frac{1}{11}$in. thick, fitted into a 2in. plate. The plate was carefully bored, and the tube carefully turned and driven in tight. These extreme proportions were intentionally selected, in order to ascertain clearly what takes place. Round the tube plate we fitted some thin sheet steel, forming a tank. This was filled with water, and placed over a smith's fire, left there a few minutes, then removed and allowed to get cold; it was then replaced over the fire, this operation being frequently repeated. After the eighth time the tube commenced to leak, and after eighteen times leaked so badly that the experiment had to be stopped. Let us now investigate what has taken place. The heat warmed the tube plate and the tube, but owing to the tube being thin as compared to the plate, the tube got hot much more rapidly than the plate. It then tended to expand, but was prevented from so doing by the plate, which remained comparatively cold, consequently the metal of the tube was permanently crushed. The exact change of form is shown on the diagram, and it will be seen that the tube has been considerably altered from its original shape.

THICK TUBE AND THIN TUBE PLATE.—We have here a thicker tube and thinner plate, the tube being $\frac{1}{8}$in. thick, and the tube plate $\frac{1}{16}$in thick (Fig. 12A). The same process was carried out as in the former case, and, although heated and cooled forty times, no sign of leakage took place. Now, in the first example we had a tube and a tube plate differing greatly in thickness from each other, and therefore they were not heated up uniformly. This caused the crushing of the tube, its permanent alteration of form, and consequent leakage. In the second experiment we had a tube and plate more nearly approaching each other in thickness, and consequently heated up more uniformly, with an absence of leakage. From these experiments it is reasonable to infer that within certain limits the more nearly the tube and tube plate approach in thickness to one another the more nearly will they contract and expand in harmony, and the less chance there is of leakage. As the tubes cannot be thickened up much and retain the necessary elasticity, it follows that to conform to these conditions the tube plate should be as thin as other practical considerations admit. Some few locomotive superintendents have used steel tubes in copper tube plates with success, and in our small experience of this combination we have had good results. At the same time, a very large majority of locomotive engineers prefer copper or brass tubes, or steel tubes with copper ends. The latter plan secures the advantage of copper in keeping the tubes tight in the plate, and also the advantage of steel in having the same rate of expansion as the boiler shell. With steel tube plates steel tubes are nearly always used, and I know of no reason leading me to believe that tubes of any other metal would be better under these conditions.

On passing from this portion of the subject, let us bear in mind that troubles due to the causes which we have up to now investigated may all be diminished by having thin tube plates. This observation refers mainly to steel or iron tube plates, as will be seen later on.

TENDENCY OF TUBE PLATES TO CURVE.—We will now proceed to consider perhaps the most interesting cause of leaky tubes. It is one which seems to have been completely overlooked by the marine engineer, though there is good reason to believe it is perhaps one of the chief sources of trouble. With a view to its investigation we have here a steel tube plate 18in. long, 18in. wide, and $\frac{1}{4}$in. thick. In it there are thirty-six tubes. Secured round the outside of this tube plate are very thin sheet steel sides, forming an open tank. This was filled with water and placed over the fire of a smith's forge, with the following result:—The bottom of the plate next the fire, always being hotter and therefore expanding more than the upper side, which was kept cool by the water, caused the plate to take a curved form. It was impossible to accurately determine the intensity of the fire, but those of us who were present feel sure that the heat was certainly not greater, but considerably less, than in the furnace of a marine boiler worked under forced draught. As stated, the plate curved, the extent of which was indicated by the inclination of the uprights as marked on the cross bars. The right hand edge of the upright B moved from C D to C E (see Fig. 9A). Fig. 13 gives a horizontal section through a boiler of a first-class torpedo boat. The dotted line shows the tube plate set out with a curvature corresponding to that indicated by this experiment, being the shape it would take if free to move. It will be noticed that we are not dealing with small alterations of form, the amount of the curvature being no less than 1$\frac{3}{8}$in. Now in a boiler this plate is not free to move, and is forced to remain flat, or nearly so. Let us investigate what happens.

REDUCING THE SIZE OF A WHEEL TYRE.—Everyone here probably knows how a wheelwright reduces the diameter of a tyre which has become loose and too large to shrink on the wheel for which it is intended. So as to refresh your memory and make this operation perfectly clear, I would draw your attention to Fig. 14, which, to better indicate what takes place, is greatly exaggerated. The black lines A B represent the tyre when cold, in its original state. The tyre is made red hot and increases in diameter, as represented by the dotted line C D. It is then immersed half its width in water. This cools the lower half, which, in consequence, contracts, but cannot do so without pulling with it the upper half, which is still red hot, the two portions making a compromise, and assuming a shape something like E B. Now the upper part, which has been reduced in diameter by force, on cooling is further reduced in diameter by reduction of temperature, and then assumes the form F B, as shown. This upper half consequently becomes permanently smaller in diameter than it was originally. The tyre is now passed through the same process reversed, the upper part in the first operation being the lower part in the second. This is repeated as often as necessary, so as to reduce the diameter to that which is wanted. This example is introduced only to illustrate how permanent alterations of form may take place when plates are subject to differences of temperature on opposite sides. It may perhaps enable us to grasp what is going on in the case of the tube plate, although clearly the conditions are dissimilar. Some interesting experiments bearing on this subject are described in a paper read before the Iron and Steel Institute in 1879 by Mr. Thomas Wrightson.

MOLECULAR STRAINS ON TUBE PLATES THROUGH THE TWO SIDES BEING SUBJECT TO DIFFERENT TEMPERATURES.—The surface of the plate nearest the fire tends to expand; the surface furthest from the fire wants to remain as it is, being kept cool by the water. The result is that these two portions of the plate, being unable to separate, are obliged to enter into a compromise, the effect of which is that the surface next the fire expands to the full extent, due to the difference of temperature, except in so far as it may be prevented through its connection with the cooler surface which it permanently stretches. Now, when the boiler is cooled down, what happens? The surface next the fire wants to contract, but that in contact with the water, not altering its temperature, does not want to contract. The two surfaces therefore enter into a fresh compromise, the result of all these compromises being, if the plate is thick and the variations of temperature are great, that a permanent distortion of the plate takes place, through this differential expansion and contraction. The holes are drawn out oval—some in one direction and some in another. Let us look at this subject from another point of view. I think we will all agree that it would be undesirable to take a plate, say $\frac{1}{4}$in. thick, and bend it from the curved form shown in dotted lines in Fig. 13, then flatten it, then curve it again, and then flatten it again, frequently repeating this operation. We should certainly expect to find the plate permanently damaged. Now, if we keep the plate flat when it wants to bend, as is the case with a tube plate, we are doing very much the same thing, although not quite so apparent. When we consider that every time the fire door is opened and closed, the plate wants to change its form and cannot do so, and when we bear in mind that the fire door in a large forced draught boiler is frequently opened and shut, say once in every minute, which in twenty-four hours corresponds to 1,440 times, it is easy to understand that the varying expansions and contractions set up severe molecular strains, and that the tube plate is undergoing very harsh treatment.

DISTORTION OF HOLE IN PLATE REPEATEDLY HEATED ON BOTTOM SIDE.—I will now describe an experiment which confirms this. We have here a plate which was kept flat, only being

Digitized by Google

allowed to move longitudinally. It was heated and cooled on the lower side, water being on the upper. It thus approached the condition under which the plate would be in an ordinary boiler. The plate was 1¼in. thick, and it had a hole very accurately bored in it 3⅛in. in diameter. It was placed over a forge arranged in such a way that a blast of hot and cold air alternately could be made to strike the plate on its bottom surface as often as required. After fifty times heating and cooling, the hole became distorted, as shown in Figs. 15 and 16, the hole at the upper surface, or water-side of the plate, being longitudinally extended $\frac{22}{1000}$in., and contracted transversely $\frac{2}{1000}$in., the hole at the bottom surface of the plate next the fire was much less altered, as shown. The black lines on the diagram indicate the original hole, and the dotted lines the distorted hole. So that the change may be clearly seen the alteration is considerably exaggerated. Fig. 17 illustrates in another way this change of form. To withstand repeated straightening and bending without damage, we shall all agree that the thinner and more flexible a plate is the better, as the reduced stretching, due to alteration of form, is then not so likely to exceed the elastic limit of the material and produce permanent distortion. It is sound argument to conclude that a thin and flexible plate has, for the same reason, an advantage over a thicker one when heated on one side and not allowed to take up the altered form which it desires.

Glass Plates Experiment.—I will illustrate in a simple manner the effect of thickness on a body, the two sides of which are subject to difference of temperature. We have here two glass plates, heated by gas on one side and kept cool on the other by water, as in a boiler.

To sum up the results, I would submit that, not only on account of the strain on the tube plate itself, which we have just investigated, but in order that the expansion and contraction of the tubes and the plate should take place as much in harmony with one another as possible, which we previously considered, it has, I think, been proved beyond all question how very essential it is to have a thin tube plate; and I think we may conclude that, so long as marine engineers adopt steel as the metal, and thick plates, they must expect trouble from leaky tubes. Probably for the same reason all flat surfaces exposed to the intense combustion of a forced draught furnace should be thin, if of steel.

Practical Conclusion.—To come to a practical determination as to what the foregoing leads, I would venture to say that any greater thickness in a steel or iron tube plate than ½in. will probably lead to trouble; ⅝in., or more, will certainly give trouble, and be always unreliable when worked in combination with forced draught. I would go a step further, and say that whoever is bold enough to adopt a ⅜in. tube plate will, I believe, not regret it. There is no good practical reason of which I am aware why a tube plate should not be made in accordance with this. As regards the width of the joint between the tube and the plate, we, as engineers, know perfectly well that, in making a steam joint, a narrow surface and a good one—say, ⅜in. wide—is all that is necessary. As far as strength is concerned, I believe it is correct to state that no part of a boiler is so well supported and so strong, stayed as it is by all the tubes, as the tube plate itself. Mr. Webb has drawn my attention to a change in the nature of the steel in fire-boxes subject to the influence of intense combustion. It appears the steel gradually absorbs carbon, and therefore alters its character, becoming more brittle. In the same way that a smith, in welding two bars of iron together, often tells us that the weld is the strongest point. If the weld is sound he is correct, because that part of the bar which comes in contact with the fuel absorbs carbon, and consequently at the joint the iron has been converted into a species of steel. The effect on the tube plate and sides by the continual absorption of carbon makes them brittle after long usage, and causes them to crack. This is well known to everybody who has had experience with steel in combination with forced draught.

Plastering Tube Plates.—We have heard of late much about plastering tube plates over with a non-conducting cement. This is an old and long since abandoned plan; none of us, I am sure, will consider it a practical solution of the problem. It is simply a temporary device, and must be looked upon as worse than useless; because it gives a power of fictitious value, and when some of the cement falls off, leaving part of the tube plate bare, the heat is concentrated upon that portion, and possibly worse strains are set up than if the entire plate were exposed. Boilers may doubtless be got through their trials by such means, or by exceptional skill and careful nursing by experienced stokers; but these must be considered as quite abnormal conditions. A boiler to be thoroughly satisfactory should undoubtedly be capable of management by men of moderate experience, and such, as in case of emergency, would be available. It is obvious that a power which cannot be obtained on service without causing boilers to leak is a mere delusion.

Setting Out of Tube Plates.—With regard to the setting out of the tubes, Fig. 18 shows two systems: in one they are zigzag, and in the other in horizontal and vertical rows. The areas of the two plates are the same, and the number of tubes is nearly so. It will be seen that with the zigzag setting out we get 1in. spaces, while with the other we get only ⅞in. spaces. From a leaky tube point of view, I believe the former to be preferable. It will be seen in that case the plate is wounded in three directions—that is, there are three directions of least sectional area of metal—while in the other case there are only two directions of least section, but the wounding of the plate at those two is greater than the wounding in the previous three. Bearing in mind the tendency of the plate to bend through being heated on one side, and that it is forced to remain flat, it follows that it is desirable to maintain as large a section of metal as possible, provided that section is not obtained by thickness. A corresponding example would be to take two bars of iron; into one make two nicks 1in. deep, and into the other three nicks ⅞in. deep. All will agree that the bar with three small nicks would be better able to withstand a transverse strain, and for this reason the zigzag setting out probably is the better. This is confirmed by the locomotive practice in this country and America.

Comparison of Copper and Steel for Tube Plates.—As to the material for tube plates, we have already seen that there is a tendency to produce curvature, owing to the difference of temperature between the two sides of the plate. In selecting a material we must, therefore, keep in view the desirability of adopting a metal which has as little such tendency to curve as possible, and, therefore, will not be much strained when kept flat against its will. To test the relative tendencies of copper and steel to curve when heated on one side only, we have here two plates precisely the same in every respect, excepting that one is of copper and the other of steel. They are 24in. long, 2in. wide, and 1in. thick. There are two uprights (see Fig. 19) and cross-bars arranged to each plate in such a way that as the plates bend the amount of curvature will be indicated by the pointers. Now, we have a row of gas-burners below these plates, and will subject them to the same treatment. On the top of the plates we have made tanks of light, flexible sheet brass, which contain water. We will light up, and on watching the pointers it will be seen to what a much greater extent the one plate curves than the other. We will now blow the flame away. This corresponds to opening the fire door, allowing cold air to rush in. Now let us put in a little cold feed. It is instructive to watch the much greater sensitiveness of the steel plate as compared to the copper one, and when we bear in mind the intensity of the combustion in a forced draught boiler, and the enormous fluctuations of temperature, as compared with what we have in this experiment, we cannot help being forced to the conclusion that copper is greatly superior to steel. In confirmation of this we have the entire locomotive practice of the country. Fig. 20 represents the respective curvatures of the two metals during such an experiment. We need not look far for the reason why a steel plate is so much more sensitive than one of copper. In Table III. will be seen their relative conductive

BOILER CONSTRUCTION.

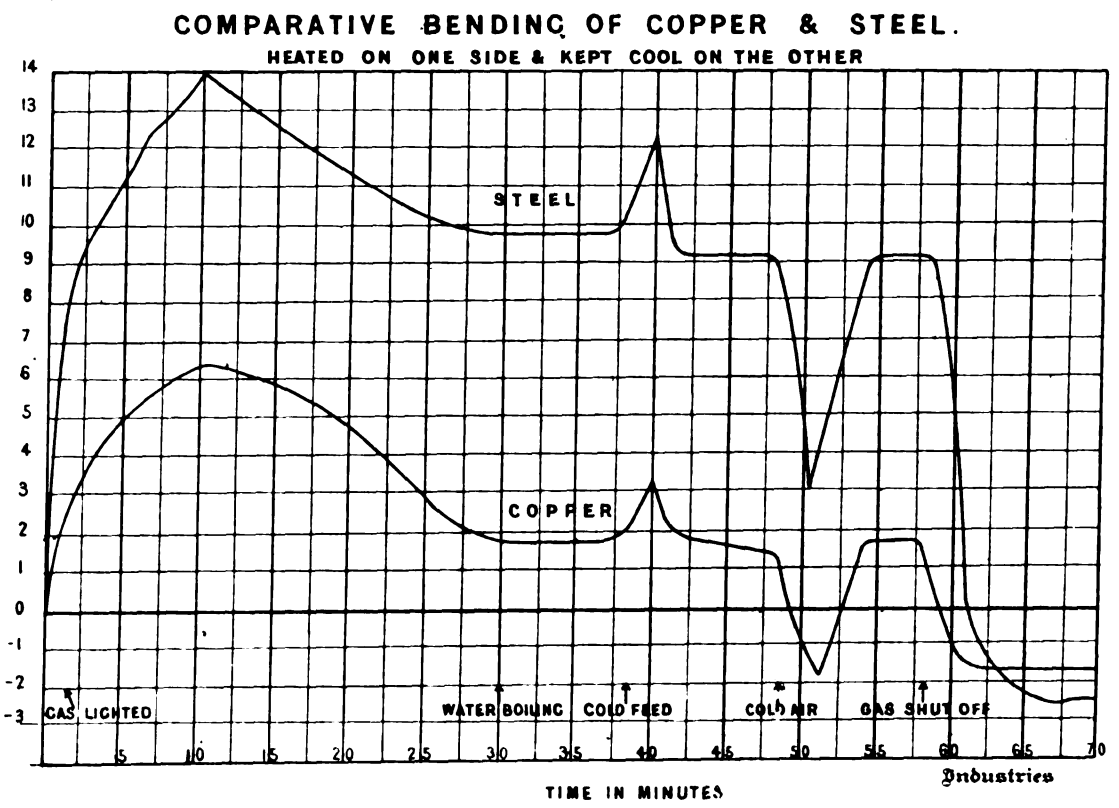

Fig. 20.

TABLE III.

Copper	6
Iron	1

powers, and the rates of expansion due to increase of temperature. Copper expands most with an increase of temperature, and is therefore inferior to steel in the proportion of 2:3; but as regards conductive power the copper is superior in the proportion of 6:1. Consequently the figures of merit may be considered to stand approximately as 12 in favour of copper and 3 in favour of steel. To put it more plainly, the copper, owing to its better conductive power, never gets heated to anything approaching the same extent as the steel, because the heat is conducted away from the surface exposed to the fire more rapidly. For these reasons we decidedly prefer copper, and have used it in all the torpedo boats we have built for foreign Powers and in a few constructed for the British Government, and we have had no reason to regret the selection of that material. It also shows why a tube plate of copper may be much thicker than if made of steel. Summing up the comparative merits of copper and steel for fire-boxes, every locomotive superintendent in this country, without exception, has far more confidence in copper. I have taken great pains to ascertain the results of actual working of the steel boxes adopted in the United States, and I am fully convinced they have more trouble from leaky tubes on the other side the Atlantic, with their steel boxes, than we have on this side with ours of copper. Our own experience in torpedo boats is unquestionably in favour of copper, in addition to which I believe we have had the reason for its superiority clearly pointed out this evening. The only point I know of against copper fire-boxes is their cost, which in the case of marine work may be estimated at from 2 to 4 per cent. of the total value of the completed vessel. It is not within my province to offer any opinion, but I submit that it is well worthy of the consideration of those whom it concerns, to determine whether this small additional cost may not be advantageously incurred, in order to obtain more reliable machinery which can withstand the extra forcing necessary when exceptionally high speeds are desired.

Galvanic Action.—The question has been sometimes raised whether any galvanic action takes place in consequence of the contact of the two metals. Experience has proved that if there exist any such action it is to a very unimportant extent, and nothing like sufficient to counterbalance the advantages of copper. In proof of this, there is the fact that many foreign Governments for whom we have built torpedo boats with copper fire-boxes many years ago, now insist upon the adoption of the same material at the present time.

Elasticity the Element of Success.—Every design is more or less a compromise, but the investigation which we have made this evening points to the importance of leaving nothing undone to ensure a design conforming to the requirements of changes of form due to changes of temperature. It also points to the importance of adopting only the highest classes of material, so as to ensure ample elasticity to help in conforming to these changes, some of which are considerable. In fact, success without elasticity is impossible. To secure this, however, people must be prepared to pay the price which such care entails; and herein lies one great difficulty, for in the present day many firms and some Governments, in their struggle for cheapness, have in reality to pay for this false economy by failure.

Conclusion.—I must now bring my remarks to a close, and only regret that time prevents my dealing with many other points which deserve attention affecting leaky tubes. I hope the few observations which I have had the honour of making may, together with the discussion to follow, point to a means of dispersing the cloud, which we must all admit hangs over our reputation as marine engineers so long as we are unable to design a boiler capable of conforming to natural laws. I trust the way may be seen to ensure to war vessels the speeds for which they were originally designed, and that naval officers may look upon forced draught, not in the light they naturally do now—as an unreliable and dangerous device—but that they may consider it as one of the greatest improvements of modern times.

In conclusion, I will take this opportunity of expressing my thanks to several members of our profession who now, and in the past, have given me valuable information bearing on the subject: among whom I might mention Mr. Adams, of the South-Western Railway; Mr. Aspinall, of the Lancashire and Yorkshire Railway; Mr. Holden, of the Great Eastern Railway; Mr. Park, of the North London Railway; Mr. Webb, of the London and North-Western Railway; and the manager of the Baldwin Locomotive Works of Philadelphia; also I wish to thank those members of my staff who have helped me in this investigation, and you, gentlemen, for having spared me so much of your time.

We have received a copy of the first number of a new journal entitled *The Optician*. The object of *The Optician* is to represent in a journalistic sense the optician and jeweller, and it will deal with the optical, mathematical, philosophical, electrical, and photographical instrument industries, as well as with the jewellery and allied trades. The first number contains articles on the Optical Exhibition, the Photographic Lens, the Meteorological Exhibition, &c., and is very neatly printed.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 7th April, 1891.

Iron.—The state of the iron market generally throughout France shows signs of a steady improvement. On the Paris market there was no change in the prices of last week, but there is a decided tendency to a further advance in quotations. In the North, as elsewhere, prices are firm. In one or two works in this district the puddlers' strike continues, but the disaffection is local, and confined to the above-named class of workmen. A contract for an iron bridge for the Nile near Mansourah has been secured by Messrs. Daydé et Pillé, Oise, who have already on hand another large bridge for the Nile near Cairo.

Copper, Tin, Lead, and Zinc.—The copper market is very firm, and there is a general rise in the prices of all classes of this metal. Best Chilian bars are quoted at £57 5s., ordinary Chilian bars at £55 5s., and best selected ore at £60 5s. per ton. There is a tendency to a further rise in quotations, as the cessation of work in the Anaconda Mines will probably cause the mineral to become scarcer. The price of tin has improved 10s. a ton on the Paris market, where the quotations during the past week were:—Banca, £99 8s.; Billiton, £96 8s.; Detroits, £95 5s.; and Cornwall, £100 5s. A large contract has been entered into for 25 tons of this ore for the Pyrotechnic School at an average price of £91 16s. per ton. The lead market is slightly firmer, and the price is quoted at £13s. 7s. the ton. Zinc is quoted at about £24 5s. the ton. The market for this metal is just now very weak throughout France.

International Congress of Miners' Representatives.—The meetings now being held at the Paris "Bourse de Travail" by the representatives of the various European coal mining centres, with the view of determining, amongst other matters, whether a general strike shall be commenced on the 1st of May next, are creating much interest here. England has 41 delegates, representing 448,636 miners; France has 23 delegates, representing 127,000 miners; Germany has 19 delegates, representing 141,531 miners; Belgium has 15 delegates, representing 92,000 miners; Austria has 1 delegate, representing 100,000 miners. The English delegates are generally adverse to a strike, as they consider the organisation in most of the Continental mining districts is far from satisfactory, and the question of throwing 8,000,000 of men out of work should not be considered lightly. The Belgian delegates are in favour of an immediate suspension of work. The French are inclined to agree with the English view of the subject, which is also favoured by the Germans, while the Austrian delegate declared that although unorganised his countrymen were ready to strike when called on.

Electric Lighting of the Orleans Railway Station.—It has been decided to light the Orleans Railway Station electrically. The system of lighting decided upon by the railway authorities is that of Messrs. Ganz & Co., and the installation will be carried out by Messrs. Schneider & Co., of Creusot.

BERLIN, 6th April, 1891.

The Zone Tariff System.—The association which advocates the introduction of the zone tariff system in Germany proposes that there shall be three zones—the first with a radius of 100 kilometres, the second with a radius of 200 kilometres, and the third zone to include distances beyond 200 kilometres. There is also a demand for an acceleration in the speed of the train service, which is at present very slow. Before the zone tariff can be introduced in Germany, considerable improvements must be made in the permanent way, and the rolling stock will have to be largely increased.

The Rhine-Weser-Elbe Canal.—This canal, which is to be 473 kilometres in length, will be cheaply constructed, and easily worked, as only twenty-five locks will be necessary. These conditions are favourable, as may be seen by comparing them with those of other canals. The Ludswigs Canal is 141 kilometres long, and has 100 locks; the Maine Canal is 33 kilometres long, and has 5 locks; the Bromberger Canal is 28 kilometres long, and has 10 locks; the Finow Canal is 45 kilometres long, and has 15 locks.

International Hygienic Exhibition at Leipzig.—An International Hygienic Exhibition will be held in the months of January and February, 1892, in Leipzig. The Exhibition will comprise, amongst others, sections devoted to hygiene, food stuffs, and ambulance.

Official Testing Establishment.—For this establishment, which is situated in the grounds of the Royal Technical College, Charlottenburg, Messrs. C. Koppe, in Berlin, are building an additional testing machine, at a cost of £2,900, which is to test up to 500 tons. Besides the mechanical testing department, there is a department for testing paper and a department for testing oil. This establishment is presided over by a competent engineer, who has a staff of about thirty assistants, and experiments are carried out for Government or private works without any profit being made.

Berlin Industries and the Chicago Exhibition.—At a meeting of influential representatives of the industries of Berlin, held on the 2nd inst., it was resolved that in the interest of trade and for political reasons it was most important that Germany should be well represented at the Chicago Exhibition. It was arranged to petition the Government to grant the necessary funds and appoint a commissioner to act in conjunction with a committee of German manufacturers in making the preliminary arrangements.

VIENNA, 6th April, 1891.

The Iron Market.—The iron market is becoming more steady, as may be seen in the continually increasing sales. The demand has considerably increased, and large stocks have been taken off the market. Merchants have been compelled to resort to bigger transactions in order to complete their stocks. Besides the demand for iron used for constructive purposes, agricultural implements and thin plates are in request.

The Coal Market.—The fluctuations in the price of coal are detailed in the following table, which gives the prices paid by the sugar industries during the past two seasons. The prices are given in kreuzers per 100 kgr.:—

District.	1889-1890.	1890-1891.	Difference per Cent.
Bustichrad-Kladno...	39·3	58·4	48
Brux	17	25·5	50
Dux Ladowitz	9·5	18	90
Bilin	18·5	25	35
Mariaschein	14·8	26·2	77
Schwaz	9·5	18·5	94
Ostrau	35	48	37
Dombrau	37·8	47·8	26

The table shows a general increase in the price of coal. In Bohemia there is an average increase of 66 per cent., but in the Moravian district there is a much smaller rise in prices. The market last week was more active than it was during the previous week, when difficulties in the loading of ships threatened to become serious.

The Harvest of Last Year.—The Ministry of Agriculture has collected statistics with reference to last year's harvest, which show the following results. The figures give the number of thousands of hectolitres, and the totals in parentheses the results of the harvest of the previous year:—

	Wheat.	Rye.	Barley.	Oats.	Maize.	Wine.
Lower Austria...	1,625	3,964	1,220	4,667	272	1,017
Upper Austria...	900	2,000	961	2,318	—	—
Salzburg	88	145	12	268	—	—
Styria	915	1,171	262	1,660	888	477
Carinthia.....	239	598	194	682	205	0·7
Carniola	305	252	248	461	378	164
Tyrol	262	409	157	152	455	250
Maritime State	305	56	152	7·4	518	545
Dalmatia.....	367	57	308	38	701	937
Bohemia	4,048	8,821	7,196	10,598	—	6·2
Moravia	1,488	3,457	2,794	4,006	138	216
Silesia	170	605	416	1,155	—	—
Galicia.....	4,482	6,395	4,478	9,989	1,700	—
Bukowina	335	458	766	665	1,464	—

The production of wheat, 15,529 (13,524); rye, 28,388 (24,945); barley, 19,137 (16,137); oats, 36,733 (28,527); maize, 6,719; (5,806), wine, 3,613 (4,106).

BRUSSELS, 7th April, 1891.

The Iron Market.—The iron market appears to be a litttle brisker, and some important orders are expected. Iron sheets are in demand, but there is a diminution in the sale of joists. Much is expected from the decrease in the price of coal, but whether this decrease will produce the results anticipated is somewhat doubtful.—The contract for the supply of turntables for the Belgian Government has been given to the Houdeng manufactory. The Conduit Supply Company has obtained an important order from the Caracus Waters Company for 40,000 metres of pipes to be delivered this year, and a large quantity of taps.—The report of the Association of Iron Masters shows that during last year the state of trade was very unfavourable, whereas in the previous year the results were most favourable. The production of foundry pig iron has much increased, but that of forge pig iron and of pig iron for steel has diminished. On the whole there was a diminution of 50,000 tons in the Belgian production last year. Out of a total of 48 blast furnaces, 34 were in blast at the beginning of the year—16 in the Charleroi district, 14 in the Liége district, and 4 in the Luxembourg district. At the end of the year there were 27 in blast—12 at Charleroi, 11 at Liége, and 4 at Luxembourg.

The Coal Market.—The placing of contracts, which is to take place to-day, is awaited with interest, and the terms of the tenders submitted are not yet known. There has been no serious fall in prices, although the market is less strong than it was a few months ago. A few sales, chiefly of steam coal and of domestic sorts, have been made at slightly lower prices. Sales of the best manufacturing sorts have been made at 12fr., and 14fr. has been asked in the open market. Coke, after remaining for a long time at 18fr., has been reduced to 17·50fr., and has even been quoted at 17fr. for large sales.

Electric Lighting at Brussels.—Tenders under new conditions for the electric lighting of Brussels are to be invited from those firms which competed under the previous conditions. The installation is to be capable of lighting 20,000 lamps, and will be erected in the centre of the city, where some ground has been made vacant by the demolition of houses. The installation is to be made with a view to future enlargement, if an increase of business should render this necessary. The conditions of tender previously issued were found to be too general, and the new conditions, which have been carefully considered by Mr. Wybauer, are more explicit and detailed. The scale of charges to be paid by the public has not yet been definitely fixed. The question is a difficult one in view of the recent diminution in the price of gas and its extended use.—Messrs. Tudor, an important firm engaged in the manufacture of accumulators, have established a branch of their business at Lille, in order to extend the use of their accumulators in France, and the shareholders of the company have taken up the new shares which have been issued for the purpose. The Tudor accumulator is likely to make rapid progress, which will be increased by certain combinations now in prospect. The Tudor system is one which yields a very fair profit on its manufacture, and the question of maintenance is solved in a satisfactory manner. Conferences have recently been held between French and Belgian electricians in order to extend the sale of accumulators in Belgium and France. As soon as certain tests now in progress have been completed the business will be started on a large scale. This new combination amongst manufacturers will cause an increase of competition, and may lead to certain claims being made by reason of an arrangement between the Faure-Sellon-Volkmar Company and a large Belgian company. Large orders of accumulators are in prospect, and this fact serves to make the competition more keen.

DÜSSELDORF, 7th April, 1891.

Iron and Steel.—The condition of the market is unchanged since the last report. Foundry pig iron, No. 1, is at 71 marks; No. 3, at 60 marks; best forge pig at 53 marks; and Thomas pig iron at 48 marks, Bessemer at 61 marks. Makers of finished iron complain of the absence of orders, and are slow to purchase raw materials.

The Coal Market.—The demand for coal and coke continues very brisk, and prices are well maintained. Tenders for the supply of 200,000 tons of coal for locomotives for the Left Bank Rhenish State Railway are under consideration at Cologne. Six of the Westphalian collieries tendered at 11 marks per ton. The "Société Anonyme de Charbonnage du Hazard" (a Belgian colliery) offered to supply the whole quantity at 10·60 marks at the pit. The award will probably be in favour of the German collieries. On the 9th inst. the State Railway at Magdeburg will award a contract for 300,000 tons of coal. The result of this award is awaited with interest, as many consumers have held back in the hope of getting cheaper rates.

Ironmasters' Meeting.—The "Vereindeutscher Eiser und Stahlindustrieller" will hold its annual meeting on the 11th inst. in Berlin. The list of agenda includes the report for the past year and a discussion of the Austro-Hungarian trade contract.

The Late Mr. F. C. Euler.—On the 27th ult. Mr. F. C. Euler died at Kaiserslautern, where he was the manager of the Kaiserslautern Ironworks. He was well known as an able engineer. In early life he founded the "Verein Hütte," from which institution sprang the "Vereindeutscher Ingenieure." This association has now more than 6,000 members, distributed over the whole of Germany and foreign countries.

AMSTERDAM, 6th April, 1891.

Dutch Chamber of Commerce in London.—The establishment of a Dutch Chamber of Commerce in London, which was first suggested by Mr. Maas, the Dutch Consul in the Metropolis, has created much enthusiasm in Holland. It seems strange that such an institution has not been in existence and flourishing for some time past, considering the many and important commercial and industrial interests that link the two nations together. However, the scheme is now fairly on its way to fulfilment. A large number of chambers of commerce and industrial and agricultural societies in Holland have joined the movement, and the new Chamber will start in London with 240 ordinary members and several life members. The Netherlands Minister at the Court of St. James's, Count von Bylandt, is the honorary president of the Chamber.

Railways.—A new and improved service of fast through trains was commenced by the State Railways Company on the 1st inst. between Paris and Amsterdam, *viâ* Brussels and Utrecht. Before that date there were only two daily express trains from Paris, one starting at 8.15 a.m., and the other at 11 p.m. This third and fast service leaves Paris at 12.40 p.m., arriving in Amsterdam at 11.35 the same evening, and thus performs the journey in less than eleven hours. Towards Germany the train service is also to be improved. The day service from Flushing to Basle will be conducted *viâ* Strassburg instead of *viâ* Cologne-Heidelberg.

Railways in the Dutch East Indies.—The Government is preparing a Bill for dealing with certain lines of railways in the Dutch East Indies, of which the necessity has been recognised, although neither the State nor private contractors are found willing to embark the necessary capital. For these railways—the principal one, of four lines, runs from Sheribon to Samarang, a distance of 244 kilometres—the Bill will recognise the necessity of granting a Government guarantee on the capital required for construction account during a certain number of years.

Digitized by Google

NEW TOBACCO COMPANY.—The Queen has approved the articles of association of the Dutch Tobacco Company "Holland," formed, with a capital of 400,000 guilders, with the object of manufacturing and trading in inland and foreign tobacco.

STOCKHOLM, 4TH APRIL, 1891.

BEET SUGAR WORKS.—The beet sugar manufacturers in Helsingborg and Landscrona have entered into an arrangement by which the area has been defined for the purchase of beets by the respective works. The growers of beets are, however, not so well pleased at this compact, as it may tend to abolish competition among buyers and to lower the prices. A large number of growers have agreed to apply to the Helsingborg Works for an advance in the price of 15 öre (2d.)

PERMANENT BUTTER EXHIBITIONS.—Two Scanian agricultural societies have voted a sum of 10,000kr. towards the holding, at Malmö, of permanent butter exhibitions for South Sweden similar to the permanent butter exhibitions in Copenhagen.

THE STONE INDUSTRY.—The stone industry in the Kelmar district appears to be annually extending, and the export, which is now considerable, comprises both common stones, for street paving, and stone for more finished work, such as monuments. Several stone-cutting works have been started, and what was formerly looked upon as valueless rock is now becoming an important source of income.

SIGNALLING THE STARTING OF MACHINERY.—At the large Husgrarna Works appliances have recently been fixed for the purpose of warning the men that the machinery is being started. From three different turbines wires are conducted to twelve different places in the works, where bells are rung as soon as the turbines are in motion. In case of accidents, the signal for stopping the turbine can be given immediately by merely pressing a knob.

"THE SHEFFIELD OF SWEDEN."—The Swedes have become very skilful in the manufacture of cutlery. The town of Eskilstuna, lying not far from the western end of Mælar Lake, is now widely known as the "Sheffield of Sweden." Here are situated a dozen or more factories, which turn out the finest cutlery and tools. Eskilstuna razors, pen-knives, and scissors are well known and highly prized in almost every country.

CHRISTIANIA, 4TH APRIL, 1891.

TELEPHONE BETWEEN CHRISTIANIA AND STOCKHOLM.—Telephonic communication between Christiania and Stockholm is likely to be soon established. The telephone line will go from Christiania to the frontier at Magnor. For the Swedish portion of the line the Stockholm-Orebro-Carlstad line will be used, with requisite extension. This arrangement has the advantage of bringing Christiania into connection with several towns in Central Sweden. It is proposed to reserve the line during several hours each day for direct communication between the two capitals.

ELECTRIC LIGHTING AT HAMMERFEST.—The installation of electric lighting at Hammerfest, which has been carried out by the Thomson-Houston International Electric Company, consists of twelve arc lamps for the lighting of the streets. The lighting of private houses is effected by means of an alternating current machine with an output of 35 amperes at a pressure of 1,000 volts. During the winter months the current will be supplied uninterruptedly, both by day and night, and the cost of working will, therefore, be very economical.

COPENHAGEN, 4TH APRIL, 1891.

THE ALUMINIA PORCELAIN COMPANY, COPENHAGEN.—This company, with which the Royal Danish Porcelain Works were amalgamated some years ago, did a larger business last year in both branches than the year before, but the net profits have not increased in proportion, owing to the high price of fuel. The balance-sheet showed, however, an increase of 151,000kr., as compared with five years ago, and a dividend of 5 per cent. was paid.

TRAMWAY COMPANIES.—The Sölvgode Tramway Company, which is the youngest of the Copenhagen tramway companies, has not yet managed to make a profit, last year's balance-sheet showing a loss on the working of 14,143kr. On the whole the Copenhagen tramways are doing very well, but several of them have required some years to attain this result.

THE COPENHAGEN FREE HARBOUR.—The Free Harbour Bill has now become law, and has already been signed by the King. Great satisfaction exists at this important measure having at last been carried through.

THE COPENHAGEN HORSE-SHOE MANUFACTURING COMPANY.—This manufactory continues to extend its business. These horse-shoes are of the best manufacture, and the home demand steadily increases as the prejudice against their use gives way. There is a large export to Brazil, Argentina, and Australia, both of horse and mule shoes, and the proprietors are now reaping the reward of their perseverance.

THE DANISH CHICORY WORKS.—The net profits last year of the Danish Chicory Factories amounted to 24,343kr. There had been a keen competition in the beginning of the year, but the company had managed to hold its own. The production was 1,934,000lb. A dividend of 3¾ per cent. on last year was declared.

MADRID, 6TH APRIL, 1891.

PURCHASE OF COAL MINES.—It is reported that Mr. Doestch has visited the Andalusian coal district of Belmez and Espiel with a view to the purchase of a group of coal mines. The coal from these mines would find a market in the province of Huelva, which requires a supply of 200,000 tons per annum, and would be carried by the Zafra and Huelva Railway, which is in the hands of the largest shareholders of the Rio Tinto mines.

BILBAO MINES.—About 2,000 workmen have been dismissed from the Bilbao mines in consequence of a decrease in the demand for the local ores. Most of them will readily find employment on the various railways now under construction in Viscay and Asturias.

IMPORTS OF COAL AND COKE.—The imports of coal and coke continue to increase notwithstanding the efforts made by owners of coal mines in Asturias to increase the output. The scarcity of skilled miners is the chief difficulty, and one of the most practical managers has stated that he will not be able to increase the output of his mines above 10 per cent. in each year for this reason. It seems strange, under these circumstances, that engineers should not resort to improved mechanical appliances. Managers of mines in Asturias would certainly gain much benefit from such enterprise, and makers of electrical plant would do well to turn their attention to the Asturias district.

EMIGRATION FROM SPAIN.—Since the year 1873 1,492,654 persons have emigrated to other countries, though several provinces in Spain are still thinly populated. This may be due either to agricultural difficulties or to defects in administration. It is certain that every article of food is dearer in Spain than in any other country in Europe.

ELECTRICAL TRACTION FOR TRAMWAYS.—The English Company, which owns the most remunerative system of tramways in Madrid, is intending to make a trial of electrical traction on a level portion of their lines. The company would thus be able to abolish the use of mules, which are a great source of difficulty.

ROME, 6TH APRIL, 1891.

WAGES OF WORKMEN.—From official reports it appears that the daily wages of workmen in 1889 compare with the wages paid in 1862 as follows:—

	1862. Lire.		1889. Lire.
Cantoni Cotton Works—spinners	1·10	...	1·94
" " " weavers	1·35	...	1·65
Rossi Wool Works—spinners	—	...	5·50
" " weavers	—	...	3·96
Sella Wool Works—spinners	2·86	...	4·35
" " carders	1·50	...	2·50
Italian Paper Manufactory—			
Rag works	0·99	...	2·28
Paper works	1·10	...	2·56
Candle Works of Messrs. Lanza Brothers—			
Men	2·16	...	3·25
Women	0·72	...	1·00
Sulphur Mines of Romagna	3·39	...	2·04
" " Sicily	2·33	...	2·35
Mines in Sardinia—native workmen	1·80	..	2·40
" " foreigners	2·25	...	3·80

The average wage of a workman in Italy is 2 lire per day. If, however, overtime is also taken into consideration, the amount is probably larger. Labour in Italy is evidently very cheap, but, notwithstanding this fact, production is more costly than in other countries owing to the fact that Italian workmen do a smaller amount of work, even though the working day is 12 hours.

SULPHUR EXPORT FROM SICILY.—During the year 1890 4,472,077 cantaras of sulphur were exported from Porto Empedocle, Catania, and Licata (Sicily) as follow:—From Porto Empedocle, 2,038,404 cantaras; from Catania, 1,320,701 cantaras; from Licata, 1,112,972 cantaras. Of these quantities, 78,763 cantaras were exported to the United States, 164,516 to Great Britain, 45,684 to France, 150,588 to Greece, 138,711 to Turkey, 1,114 to Sydney, 3,982 to the British colonies in Asia, and 327 to the French colonies in Africa.

LAUNCH.—On the 28th ult. a fine steel sailing vessel was launched from the shipbuilding yard of Pertusola. This is the fourth steel vessel built in that yard. Lord Brassey and his brothers were present at the launch.

EXHIBITION OF THE BUILDING INDUSTRIES AT PADUA.—This Exhibition, which was to have been held in the town of Padua in the months of May and June next, has been indefinitely postponed.

NEW YORK, 28TH MARCH, 1891.

EXTENSIONS OF WORKS.—The Illinois Steel Company announce that they are about to build an extensive plant at Bay View for the manufacture of cast-iron pipes of every description. The new plant will cost $500,000, and will give employment to 500 men. It will cover about three acres, and will be located about a quarter of a mile north of the rolling mills. The buildings are to be of stone, brick, and iron, and the material for pipe casting will be conveyed direct from the company's blast furnace. This will be by means of an elevated railway from the blast furnace to the new mills, the molten metal being conveyed in small iron cars. Between 400 and 500 tons of pipes will be turned out daily.—The Brown & Sharpe Manufacturing Company, of Providence, R.I., are adding a new four-story brick building, 100ft. long and 56ft. wide, to their already large works. The new building will be devoted to the manufacture of a variety of small tools and instruments for accurate measurements.

PROFIT SHARING.—The profit sharing system adopted by the Ingersoll-Sergeant Rock Drill Company has worked very successfully. During the past year the company declared an employés' dividend of about $6,000, dividing it as a bonus among the employés of the shops and offices. The sum was larger during the year 1890 than previously, due to the large increase in business.

TELEPHONE RATES IN NEW YORK.—The New York Legislature is considering a Bill which provides for a reduction of the price of telephone service in cities of over half a million inhabitants. It provides that telephone companies must furnish service to all persons within their districts applying for the same in cities of more than 500,000 inhabitants at the rate of $75 per year. A higher price may be charged where an exclusive wire is furnished. The supporters of the measure say that a $75 rate will yield a liberal dividend on the capital invested in the Metropolitan Telephone Company, and add that single subscribers in some parts of the city are refused instruments and service, even at existing rates, on account of the trouble and expense of connecting them. The company contends that it cannot furnish the service at a $75 rate, and that if the Bill is forced the improvements now in progress and contemplated must necessarily be discontinued. It is expected that the assembly committee will report favourably on the Bill.

MORE MINING INSPECTORS.—A Bill has been introduced in the West Virginia Legislature increasing the number of mine inspectors from two to four, and establishing rules and regulations for the more careful inspecting of mines. The Bill provides punishment for the operators and the men under them if they neglect to see that ventilation and other matters of importance to safety in mining are properly looked after. The Bill provides for one mine inspector for each congressional district, and as the congressional districts are now arranged each inspector will have as much as he can possibly do to properly attend to his duties and cover his district. This is made necessary by the rapid growth of the mining industry in all sections of the Mountain State.

PHILADELPHIA, 27TH MARCH, 1891.

NAVAL.—The gunboat "Bennington," which was built by the Delaware River Iron Ship Building and Engine Works, at Cluster, Pa., and which failed to develop the necessary speed on her recent trial trip, was docked at New York on the 19th inst., that her propeller might be examined and altered. The "Concord," which was built on the same lines by the same company at the same time as the "Bennington," on her trial trip recently exceeded the requirements imposed by the Government.

PUBLIC WORKS.—The fourth and last annual report of the Department of Public Works under the present administration shows an increase in receipts of $1,420, and a decrease in expenses of $44,470. In the water bureau the receipts have increased by $896,000, and the total profits in the past four years were $4,260,000. The total rainfall in 1890 was 34·68in., which is 16in. less than during the previous year. Notwithstanding this decrease, the water of the Schuylkill was ample for all purposes. The report suggests the necessity of authorising the Department of Public Works to prepare plans for a permanent water supply for the city of Philadelphia, other than by pumping from the Rivers Delaware and Schuylkill within city limits, the water in these rivers being frequently polluted by the discharge from factories and mills.

STANDARD STEEL WORKS' STRIKE.—The strike among the moulders of the Steel Casting Works at Thurlow still continues. The company sent for a number of moulders from New York and Brooklyn, but upon their arrival here they were persuaded by a committee from the Brotherhood not to work. The Standard is the most successful of about eight companies of its kind in this country. A great quantity of Government work and many orders for the general trade are in hand at this time. About fifteen out of eighty moulders have remained at work. A moulder requires at least two years' experience at the open-hearth process before he can do the work efficiently, however successful he may have been as a moulder at other processes.

THE COKE STRIKE.—Some of the workmen have decided to resume at the 10 per cent. reduction. At present the following works are running:—Raimy's, 1,018 ovens; Mt. Braddock, 130 ovens; Pennsylvania, 88 ovens; Percy, 62 ovens; in all 1,358 ovens, out of 16,119 ovens. The Dunbar Furnace Company's plant, and others, amounting to about 500 ovens, will resume shortly. The McClure and Frick Companies, which control the remainder of the ovens, have as yet made no move.

COAL PRODUCTION IN THE WEST.—The Census Office has issued a bulletin showing the production of coal in the States west of the Mississippi River. The production in 1889 was 16,067,500 tons, of which 10,051,229 tons were mined in the Trans-Mississippi Valley, 4,836,368 in the Rocky Mountain region, and 1,179,903 on the Pacific Coast. The production in 1880 was 4,854,324 tons. But while the product in 1889 was more than three times as great as that in 1880, the value is shown to have decreased from $1·93 per ton at the mines in the Mississippi Valley to $1·52. The kinds of coal found in the Western States and territories comprise lignite, bituminous, and anthracite, all suitable for steam and heating purposes, as well as for gas, coking, and smelting.

THE ROYAL NAVAL EXHIBITION.

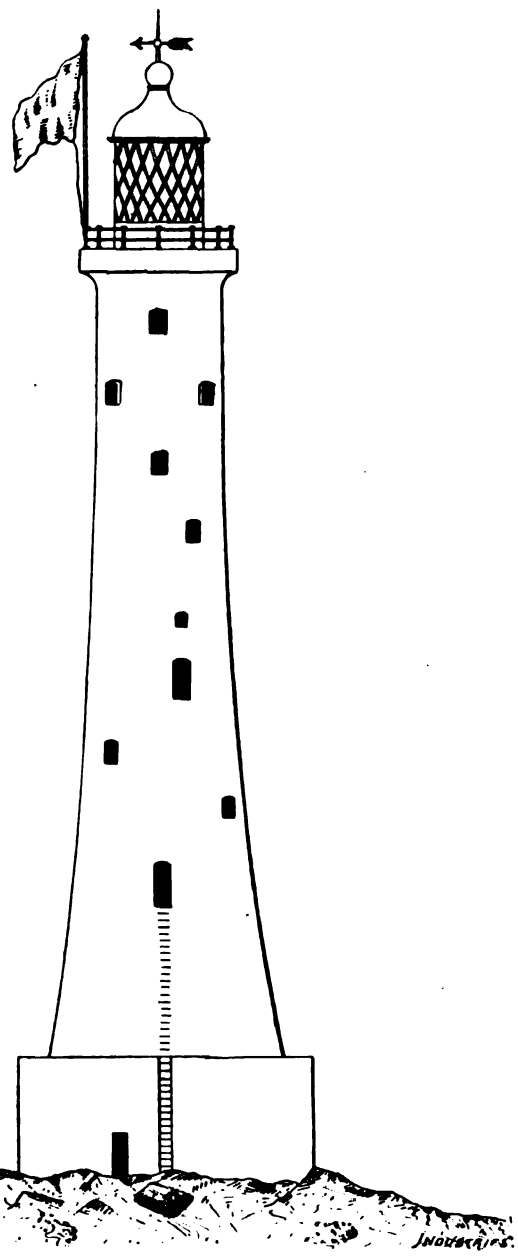

FIG. 1.—ELEVATION OF EDDYSTONE LIGHTHOUSE MODEL.

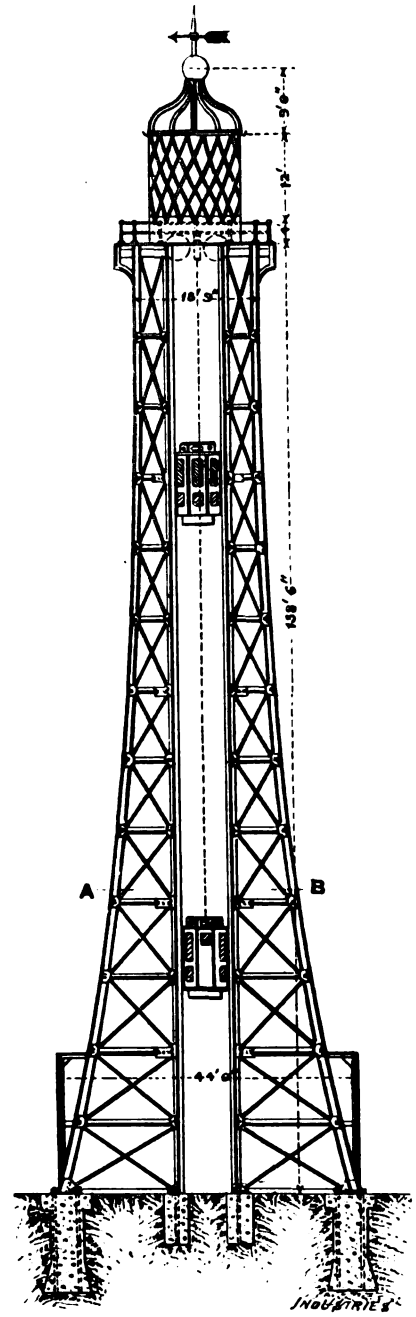

FIG. 2.—VERTICAL SECTION OF MODEL.

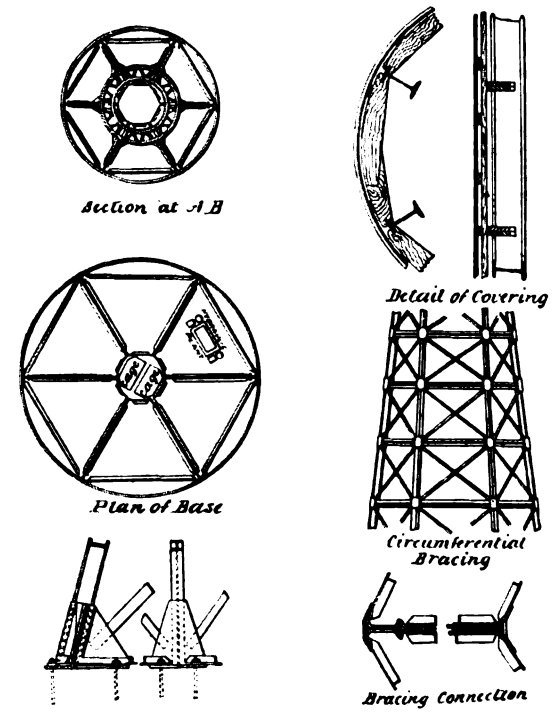

FIG. 3.—STRUCTURAL DETAILS OF MODEL.

THE ROYAL NAVAL EXHIBITION.

IN our issue of the 6th ult. we gave a general description of the work now being carried on at the site of the Naval Exhibition, and now propose to refer to one of the most interesting features of the Exhibition. This will be a full-size representation of the new Eddystone Lighthouse. Externally it will be a perfect representation of the original structure; the windows, doors, ladders, lantern, and even the courses and size of the stones are being accurately copied, and the rocks upon which the original structure is erected as they appear at low water will be faithfully represented in the Exhibition model. Internally, the structure consists of a steel and iron framework, covered first with wooden battens and laths, which in their turn receive the fibrous plaster slabs, the natural colour of which very nearly approaches that of the granite in the original structure. The framework consists of six braced main ribs radiating from the centre, and so constructed that when erected a clear hexagonal space, 9ft. wide, is left in the centre, in which are placed the two passenger lifts for taking visitors to the top. The ribs are constructed of steel and wrought-iron rolled beams, tee, angle, and flat bars firmly bolted together, each rib being divided into thirteen bays, the level of each bay corresponding with the floor lines in the original structure. The main ribs are secured by thirty-six strong iron bolts firmly attached to strong anchor plates embedded in cement concrete nearly 20ft. below the surface of the ground, the stability of the structure in the heaviest possible gale being thus ensured beyond doubt.

The height of the structure from the ground to the centre of the focal plane is about 150ft., and to the top of the lantern roof is about 170ft.; the base is 44ft. diameter and 19ft. high. From this base—which has vertical sides—springs the curved structure, having a diameter of 35ft. 6in. at the bottom, and of 19ft. at a point 6ft. below the lantern platform. From this point the structure swells out to a diameter of 24ft. at the platform, upon which is erected the lantern to receive the lighting apparatus. The lantern is 14ft. diameter, thus leaving a gallery 5ft. wide all round; it is 16ft. 6in. high, and is glazed with diamond-shaped panes as in the original, the whole being surmounted by the wind vane, which is a copy of the original, and is 8ft. long. There are nearly 100 tons of iron and steel in the structure, made up of over 1,000 pieces, all of which have been marked, drilled, cut, or bent to the required shape; so some idea can be formed of the immense amount of planning and labour entailed in the construction of what is only a temporary structure.

The passenger lifts referred to have been specially designed for the structure, the first consideration having been given to the safety and comfort of the visitors ascending. They consist of two cages, each capable of holding eight passengers, worked somewhat on the principle of those on the cliffs at Scarborough and at Folkestone. A tank is placed under each cage, with valves so arranged that it can be filled or emptied in a very short space of time. The cages act simultaneously, being connected by steel wire ropes over pulleys at the top, so that while one is discharging the passengers at the top the other is being filled at the bottom. To put the cages in motion, the tank of the top cage is filled with water, and that of the bottom one emptied, so that the top car descends by the action of gravity and pulls up the other one. The speed of the cages is regulated by an ingenious "cataract" cylinder, actuated by the man in charge, and automatically when the cages approach the top or bottom. This cataract cylinder ensures perfect safety, and is most simple in its action. An additional security, however, is obtained by means of a powerful friction brake on the top shaft; so there is not the slightest possibility of the cages running away. The steel ropes which sustain the cages are four in number, although one rope alone is sufficient to bear the whole load of the cages when full of passengers and after allowing a large factor of safety. Again, should the ropes break, powerful grips immediately clutch the vertical guides, and the cage would not fall more than an inch before it would be brought to a standstill. It will thus be seen that the cages may be considered absolutely safe. Powerful steam pumps are fixed in the basement to force the water into the tanks at the top, whence the water flows to actuate the cages. These pumps are in duplicate. The cages are made of polished walnut and other ornamental woods, well upholstered, and fitted with bevelled mirrors and ornamental lead lights in the roofs.

Referring to the illustrations, Fig. 1 shows an outline view of the model of the Eddystone lighthouse; Fig. 2 shows a vertical section; Fig. 3 some details of the structure, and Fig. 4, on page 348, gives a general view of the lighthouse as it appears during construction.

The structure, the framework of which is illustrated above, will be illuminated at night by a powerful revolving electric light constructed by Messrs. Chance & Co., of Birmingham. Visitors will be allowed to go either inside the lantern, where they will have an opportunity of inspecting the magnificent lighting apparatus, or on the balcony outside, from which a splendid panoramic view of the winding of the River Thames and of the country for miles around will be obtained. To prevent any accidents from the top, the balcony is protected by strong wire netting securely attached to the structure; this security also gives visitors confidence when looking out from such an elevation.

The whole structure was designed by Mr. John J. Webster, M.Inst.C.E., and has been erected under his superintendence by Mr. D. Charteris, builder and contractor, of Page Street, Westminster, the passenger lifts being constructed by Messrs. R. Waygood & Co., of Falmouth Road, London.

In connection with this Exhibition, we may mention that the Fire Brigade appliances are under the control of Messrs. Merryweather & Sons' fire inspectors, who are engaged to instruct a brigade to be formed from ordinary seamen.

THE INSTITUTE OF MARINE ENGINEERS.

A MEETING of this Institute was held on the 24th ult., at which was read a paper by the President, Mr. G. W. Manuel, on "The Influence of Mountains on the Health, Wealth, Political Independence, Habits, and Pursuits of Mankind." Mr. Manuel in his paper drew attention to the works of the Great Engineer whose laws we should endeavour to learn and obey. The author spoke of the beneficial influence of mountains, and showed that, were it not for mountains, man could not exist in some parts of the earth. The effect of mountains on the rainfall and temperature was particularly noticed. As an instance, the city of Quito, in the torrid zone, had a mean temperature of 53°. The rise of the Nile, and the consequent fertility of Egypt, was due to the mountains in Central Africa. Were it not for mountains, much of the mineral treasures would be beyond our reach.

The Chairman said that Mr. Manuel had found out that they had more than one section of engineers in the Institute; there was the sea-going section, and the stay-at-home section. He thought that a paper like the one Mr. Manuel had read was an agreeable change from dry mechanical papers, and gave the members much pleasure. A hearty vote of thanks was given to the author and the members who had joined in the discussion.

The following meetings of the Institute are fixed for the second and fourth Tuesdays in April and May.

SHIPBUILDING NOTES.

ON the 24th ult. Messrs. Richardson, Duck, & Co. launched from their building yard the steel screw steamer "Velleda," of the following dimensions, viz.:—Length, over all, 307ft. 4in.; depth, extreme, 40ft.; and depth, moulded, 21ft. 8½in. This vessel, which has been built to the order of Messrs. Carlisle & Co., London, is classed 100 A1 at Lloyd's, and has been built under special survey. The engines are triple-expansion, by Messrs. T. Richardson & Sons, Hartlepool.

ON the 26th ult. Messrs. Ropner & Son launched the steel screw steamer "Aymestry" of the following dimensions, viz.:—Length, over all, 324ft.; breadth, 40ft. 6in.; depth, moulded, 23ft. 7in. She will be classed 100 A1 at Lloyd's, and carry 4,400 tons deadweight on Lloyd's summer freeboard. The vessel is provided with a cellular bottom for water ballast, and is built on the web frame principle. The engines are by Messrs. T. Richardson & Sons, on their improved triple-expansion principle, of 1,200 indicated horse-power, with two large steel boilers working at 160lb. The steamer has been built for Messrs. Sivewright, Bacon, & Co., West Hartlepool.

ON the 31st ult. the steel sailing ship "Bardowie" was launched by Messrs. Wm. Hamilton & Co., Port Glasgow. The length of the vessel is 267ft.; breadth, 41ft.; depth, 24ft. 6in. The register tonnage is 2,060. The carrying capacity is 3,500 tons. The ship has been built to the order of Messrs. Hamilton, Harvey, & Co., Port Glasgow.

ON the 31st ult. Messrs. Thomas Russell & Co., Greenock, launched a steel sailing ship of 1,700 tons, which they have built to the order of Mr. G. T. Soley, Liverpool.

ON the 7th inst. the "Chilian," a steel screw steamer, was launched by Messrs. Robert Napier & Sons, Govan. The vessel has been built to the order of the Campania Sud Americana de Reanores, Valparaiso, and is intended for the Pacific coasting trade. The two sets of engines are of the triple-expansion type.

Notices of Meetings.

THIS WEEK.

ROYAL INSTITUTION.—Friday, April 10th, at 9 p.m. Lecture on "Electric and Magnetic Screening," by Sir William Thomson, Pres. R.S. Saturday, April 11th, at 3 p.m. Lecture I., on "The Dynamo," by Professor S. P. Thompson.

INSTITUTION OF CIVIL ENGINEERS.—Friday, April 10th, at 7.30 p.m. Students' meeting. Papers to be read: "Modern Locomotive Construction," by Mr. W. W. F. Pullen; "The Design of Locomotive Cylinders," by Mr. J. H. Barker.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.—Friday, April 10th, at 7.40 p.m. Discussion on Mr. W. C. Mountain's paper on "Electrical Engineering with Special Reference to Electric Lighting." Paper II., on "The Unsinkability of Cargo-Carrying Vessels," by Mr. W. Hök.

SOUTH STAFFORDSHIRE INSTITUTE OF IRON AND STEEL WORKS' MANAGERS.—Saturday, April 11th, at 7 p.m. Papers to be read: "Electric Cranes," by Mr. W. D. Sandwell; "Varieties of Tap Cinder," by Mr. T. Turner.

MANCHESTER ASSOCIATION OF ENGINEERS.—Saturday, April 11th, at 7 p.m. Paper to be read: "The Manchester Ship Canal," by Mr. T. Ashbury.

NEXT WEEK.

INSTITUTION OF CIVIL ENGINEERS.—Tuesday, April 14th, at 8 p.m. Paper to be discussed: "The Cost of the Generation and Distribution of Electrical Energy," by Mr. R. E. B. Crompton, M.Inst.C.E.

ROYAL INSTITUTION.—Tuesday, April 14th, at 3 p.m. Lecture on "The Geography of Africa," by Mr. J. S. Keltie. Thursday, April 16th, at 3 p.m. Lecture on "Recent Spectroscopic Investigations," by Professor Dewar.

SOCIETY OF ARCHITECTS.—Tuesday, April 14th, at 7.30 p.m. Paper to be read: "Wood Carving," by Mr. W. Aumonier.

ROYAL VICTORIA HALL.—Tuesday, April 14th. Lecture on "The Extinct Volcanoes of France," by Dr. Crosskey.

ROYAL METEOROLOGICAL SOCIETY.—Wednesday, April 15th, at 7 p.m.

SOCIETY OF ARTS.—Wednesday, April 15th, at 8 p.m. Paper to be read: "The Sources of Petroleum and Natural Gas," by Mr. W. Topley, F.R.S.

PRICES CURRENT, 8TH APRIL, 1891.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. G. Bailey Toms & Co., London, quote as follows:—

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER remains inactive, with small business taking place. Chili bars have been unsteady during the week, having touched as low as £52 5s., but have again recovered, quotations to-day being £52 10s. to £52 15s. cash. The total visible supply of copper decreased about 670 tons during March. Manufactured steady at £65, "strong."

TIN: Firmer, an advance of about 10s. having taken place to-day in foreign.

LEAD: Quiet; values a shade lower.

SPELTER keeps firm, and stocks continue unusually small.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS: The course of business continues uneventful, many articles being very dull. Sulphate of ammonia is lower in value, and few orders are being placed at present. Carbonate of ammonia also is quiet. Carbolic acids are without change. Benzoles are easier, and very little doing. Sulphate of copper is weak, second-hand parcels being plentiful. Arsenic is lower. Yellow prussiate of potash is firm. Sulphur of all qualities is scarce.

WE have received a small work, entitled "Architectural and Enriched Casings for Electric Wires," by F. A. Fawkes, which is really a highly illustrated price list of artistic casings. Mr. Fawkes' designs are especially good.

WE have received a copy of the latest catalogue issued by Messrs. Bowes, Scott, & Western, engineers, Westminster, of their mining machinery, which embraces all the usual machinery and appliances required in mining, such as engines, pumps, winding gear, crushing and stamping machinery, wire ropeways, portable railways, &c.

ELECTRIC LIGHT CABLES.—The India Rubber, Gutta Percha, and Telegraph Works, Company, Limited, Silvertown, send us a book that resembles a catalogue, but is mainly really a treatise on highly insulated cables. Though it is avowedly written to push the sale of the Silvertown cables, it will be found well worthy of careful perusal by electric light engineers generally.

POCKET EDITION OF THE DIRECTORY OF PAPER MAKERS FOR 1891 (London: Marchant Singer & Co.).—The contents of this little book are practically the same as those of the "Directory of Paper Makers of the United Kingdom for 1891," which we noticed a few weeks ago. The "Pocket Edition" is, however, of such a size that it can easily be carried in the pocket. It should therefore prove very convenient as a means of reference.

WE have received a copy of the third edition of a little work by Mr. H. Swan, entitled "Travellers' Colloquial French." The book is full of very useful idiomatic French phrases, with the pronunciation represented in English on a new system based upon a scientific analysis of French sounds. In addition to the useful French phrases, the little work contains much information relating to the manners and customs of the French people, which will be found useful by intending visitors. The third edition has been enlarged by the addition of a number of phrases for cyclists and amateur photographers which should prove useful.

HOME INDUSTRIES.

LONDON, 9th April, 1891.

The Money Market.—The payment of the dividends on the Government Funds at the beginning of the week supplied the market plentifully with money, and rates at once fell away until loans from day to day were worth little more than 1 per cent. The discount rate has also moved in the direction of ease, but not to the same extent, the apprehension of gold withdrawals keeping it steady. No revival has yet manifested itself in Stock Exchange business, in which very little interest is shown. The account dealt with at this week's settlement was very light, and easily arranged. No new feature was revealed by it, but the continued existence of a large speculation for the fall in home railways was further proved. The prices of these stocks hardened in consequence, and a number of the more nervous "bears" have been buying to cover their commitments. American railways, after a couple of days of improving quotations, have received another check, and Canadians, notably Grand Trunks, have been similarly disappointing after giving fair promise of a sustained recovery. In the foreign market fears regarding the political equilibrium in South-East Europe have disturbed the stocks belonging to States in that quarter. South American bonds are little favoured, and show, without an exception, a strong tendency to fall to a still lower level of prices. Among miscellaneous and industrial shares, those of the Hammond Meat Company and the Middlesborough Town Company of Kentucky have been attacked, and have fallen lower. Copper shares are steady, but there is little doing in mining values in general.

The Great Northern Telegraph Company.—The traffic returns of this company show that the receipts during March were £22,800. The receipts from 1st January to 31st March, 1891, were £64,400, whilst for the corresponding months of 1890 and 1889 they were £60,200 and £63,000 respectively.

The Patent Office.—The indices of patents, published at the Patent Office, have of late years been in a state of great confusion, to the annoyance and inconvenience of readers. Some practical and experienced searchers recently presented a memorial on this subject to the Patent Institute, with a view to representations to the Board of Trade. In consequence of this memorial a deputation of searchers met the sub-committee of the Institute, on the 24th ult., in order to discuss the matter. The deputation pointed out the comparative excellence and uniformity of the "Bennet Woodcroft" indices, up to 1870, and urged that the 1881 index should be as closely imitated as possible, and that the whole of the indices, from 1870 to the present time, should be made uniform with that model.

Electric Light Exhibition at the Crystal Palace—The directors of the Crystal Palace have decided to organise a second Electric Light Exhibition, which will be opened in the autumn. Every endeavour will be made to render this second Exhibition complete and popular. In addition to the various systems of lighting, the exhibits will comprise telegraphs, telephones, signals, batteries, electromotors, cables, lightning conductors, magneto-electric and dynamo-electric machines, and all other apparatus, instruments, machinery, and material connected with the production and transmission of electricity.

Smokeless Fuel.—On the 7th inst. a trial of a new smokeless fuel was made before the Prince of Wales and other members of the Royal family, at the premises of Messrs. Brewis Brothers, York Road, King's Cross. The trial was made by Mr. Koopman, the inventor, and Mr. Guy Rottmann, of 11, Lovell's Court, Paternoster Row, London, who is introducing the fuel into this country, on a small Cornish boiler which supplies the steam required for driving an adjacent works. The fuel, which we have had an opportunity of inspecting, consists of dust or waste coal reduced to a fine powder, and then incorporated with a small proportion of pitch and some other mineral substances to the extent of from 7 to 10 per cent., according to the nature of the coal used. It is then, while in a plastic condition, moulded in presses, where it is submitted to a pressure of two tons per square inch, and assumes the form of briquettes about 8in. long by 5in. wide and 4in. thick. It is stated that the mineral ingredients thus added produce during combustion a gas which not only consumes the smoke that emanates from the coal, but also all noxious fumes. The sulphur is said to be rendered innocuous, and the heat generated to be greater than that produced by ordinary coal alone. The briquettes are manufactured at the Cossall Colliery, near Nottingham.

Electric Launches on the Thames.—Messrs. Woodhouse & Rawson United, Limited, have decided to erect a permanent charging station on the banks of the Thames at Chertsey, under the management of Mr. J. Taylor. The station will be quite ready to undertake the charging of electric launches of all sizes at the beginning of the river season.

Institution of Civil Engineers.—Last night the annual dinner of the Institution of Civil Engineers was held at Merchant Taylors' Hall, under the presidency of Sir John Coode. The Duke of Teck was present, together with a large number of other guests and members of the profession.

Exhibition of the Painting Trade.—An exhibition and competition of graining, marbling, sign writing, and decorating, suggested by the *Journal of Decorative Art*, is to be held in the Painter Stainers' Hall, Little Trinity Lane, London, E.C., from the 18th to the 27th inst. inclusive. Numerous prizes are offered for the various classes of exhibits. The hall will be ready for the reception of exhibits on the 13th inst., and none will be received after 4 p.m. on the 14th inst. The Exhibition will be open each day from 11 a.m. to 9 p.m., and admission will be free.

MANCHESTER, 9th April, 1891.

Electric Lighting.—Some time ago the Gas Committee of the Manchester Corporation appointed a sub-committee to inquire into the best method of lighting the central portion of the city by electricity. This committee has visited Bradford and London, and investigated both the low-pressure continuous and the high-pressure alternating current systems. They report that, although ample evidence is forthcoming with reference to the first cost of installations, the cost of working was not so readily ascertained. The opinions obtained and the methods examined vary so largely that the committee cannot themselves come to any definite conclusion, but recommend that the best professional advice should be obtained, so that a complete scheme may be drawn up for carrying into effect the provisional order. The Gas Committee, after considering the report, has authorised its sub-committee to take such action as they may think advisable.

Purifying Coal Gas.—The Dukinfield Local Board have determined to apply the new oxygen process of purification at their works. The cost of the plant is about £4,000, and it is anticipated that a great saving will accrue from the less frequent "changes" in the purifiers. The purification of gas is a question of much interest at present in this district, and much dissatisfaction is expressed with the quality of the gas supplied by some of the local bodies.

The Ship Canal.—By a large majority the citizens of Salford have expressed an opinion that the Corporation of that borough ought to render immediate aid to the Ship Canal Company. At present the Corporation is considering the subject, but its action is thought to be rather sluggish, especially in view of the introduction of a Bill into Parliament.

"Cleaning Time" in the Cotton Trade.—A dispute has arisen between the employers' and operatives' associations in the spinning trade, owing to the demand of the operatives that the time for cleaning the machinery should be extended. In view of pending legislation the employers decline to grant any extension, and the operatives have been empowered to strike in any case where their demand cannot be obtained by negotiation.

The Linen and Jute Trades.—A better tone is now evident, and distributors are hopeful of recovering any losses incurred during the period before Easter by increased activity between now and Whitsuntide. Prices of pales and roughs have been improved by an advance in quotations for tow yarns, while a rise in high counts of linens helps manufacturers of fine linens to keep up prices, and even to obtain fractional advances where goods are required for special orders. A slight increase in the demand for sheetings and other descriptions of bed linen is noticeable, and the Barnsley section of the trade appears to be improving slightly. It is evident from what has taken place in the markets for raw and finished material during the past week that linen prices show a tendency to rise. A steady effort has been made by manufacturers to raise quotations to a higher level, although with dearer flax, and therefore dearer yarns, little advantage is to be gained. Linen cambric handkerchiefs, embroidered by machine in Switzerland, are now being introduced into the United States, and the goods will compete keenly with the hand-embroidered product of Belfast. Jute goods are rather slow, although reports from northern markets are cheerful. The mills are fairly busy on United States' account.

Electric Lighting of Victoria Station.—An installation of forty arc lamps of 2,000 candle-power each, of the Brockie-Pell type, has been erected by the Lancashire and Yorkshire Railway Company for the lighting of Victoria Station. The lamps are arranged on four circuits of ten each. The generating plant consists of three dynamos constructed by Messrs. Mather & Platt, which are placed in the engine-house adjoining the head offices in Hunt's Bank. Two locomotive engines have been adapted, so as to be used for driving the countershaft to which the dynamos are belted. Two only of the dynamos are used at once, the third being held in reserve. Each machine will generate sufficient current for half the lamps in the station. It is intended ultimately to lay down a much larger plant in a more central position, from which the whole of the station, offices, and approaches will be lighted.

GLASGOW, 9th April, 1891.

Export Trade.—As might have been expected from the slackness of trade during the past three months, and from the partial paralysis of it during the month of January caused by the strike of railway servants, the quarterly returns for the Clyde are very low. The tonnage of vessels arriving at the Clyde ports during the quarter is less than the corresponding tonnage for the last quarter of 1890, and also less than for the March quarter of 1891, by fully 25 per cent., the falling off being about 70,000 tons. The departures show a similar decrease, having fallen from 476,984 tons for the last quarter of the year 1890, and 422 141 for the March quarter, 1890, and 533,877 tons for the quarter ending December, 1889, to 385,061 tons for the quarter just closed. The principal falling off is in iron and general machinery, and in a less degree in cotton. Locomotives, steel, sewing machines, and linen goods show an increase. The decline in cotton shipments has been chiefly in exports to the United States. The increase of about 15 per cent., amounting to £40,000, in the exports of linen to the United States is remarkable. The returns prove that foreign trade is at present declining, though, as was observable during similar conditions about ten years ago, miscellaneous industries have not suffered so much as the staple trades. The increase in linen shipments and the falling off in cotton shipments are an incidental confirmation of this. Even if we take into account the balancing of one commodity in a complementary group against another, there is a general falling off, which can only be attributed to an approaching period of depression of trade.

Electric Lighting in Glasgow.—The Corporation of Glasgow are still undecided about their provisional order. Deputations have been visiting Bradford, Leeds, and other places, but so far they have come to no decision whether to accept one of the tenders already received or to embark in central station lighting on their own account. This indecision is retarding the development of electric lighting in the city.—The Central Railway Station and Hotel have just been completely fitted with electric light by Messrs. Mavor & Coulson. The work has been done under the superintendence of Mr. Dunn, superintending engineer of the Caledonian Railway Company.

Shipping.—Messrs. J. & N. Allan, who have acquired the State Line steamers, and who have just established a line from the Clyde to New York, have appointed as their agents in the latter city Messrs. Austin, Baldwin, & Co., who have represented the State Line there for the past twenty years.—Freights are still very dull. Several contracts forward have been made at low rates, including Glasgow to San Francisco (ship now building), 15s. 6d.; San Francisco, homewards, 38s. 9d., for loading twelve months hence.

The North Railway Service.—The fast train service from London to the North began for the season on the 1st inst. The distance between London and Aberdeen, *viâ* the Forth and Tay Bridges, 526 miles, is covered in twelve hours by the train leaving London at 8 p.m. By the East Coast route the first train leaving London at eight o'clock on the 1st inst. reached Aberdeen at 7.55 a.m. next morning, five minutes before time. On the same evening the London and North-Western train leaving at the same hour reached Aberdeen at 8.3 a.m., only eight minutes later than the East Coast train. The difference in distance is fourteen miles, the West Coast route being 540 miles against 526 miles by the East Coast. Since both trains travel on the same line north of Kinnaber Junction, near Montrose, it is arranged that whichever train reaches the junction first proceeds first, the line being blocked from station to station.

Railway Bills.—The Clyde Trust have determined to petition Parliament against the Steam Vessels Bill promoted by the Glasgow and South-Western Railway. If this Bill should be passed there will be an end to individual private enterprise in the Clyde coasting traffic, as the whole of the traffic will fall into the hands of the three leading railway companies.

(From our own Correspondents.)

LIVERPOOL, 8th April, 1891.

The Timber Trade.—Although the deliveries have been satisfactory for the time of the year and the imports moderate, the stocks are far too heavy, and the prices have not improved, contracts being made with difficulty. The stock of yellow pine, waney and square, is excessive, and the demand moderate, and red pine is not in demand, the stock also being heavy. The consumption of pitch pine has improved, and there have been no arrivals of hewn wood, four cargoes of sawn having arrived from Pensacola, three for contract, and one to be sold by auction; the stock is very heavy and prices are low. There has been no import of New Brunswick and Nova Scotia spruce deals; the stock is heavy, prices low, and no prospect of improvement. No Quebec and United States oak has been imported in the log, but several lots have changed hands; the stock is heavy and the prices low. Oak plants are in fair request, the deliveries have been good; the stock is moderate, and prices are firm. There has been a strong inquiry for greenheart, and the consumption has been about 10,000 cubic feet; the market is empty and prices are high. The stock of teak is exceedingly heavy, and the consumption has equalled the import. The stock of elm is moderate, the demand fair with no change in prices. There has been a good demand for ash, but the stock is heavy.

Large Imports of Live Stock and Dead Meat.—During the past three months there have been landed from the Canadian and American ports 40,724 cattle, 213,496 quarters of beef, and 1,344 hogs, being an increase on the imports during the corresponding period last year of 9,105 cattle, and 12,941 quarters of beef.

LEEDS, 8th April, 1891.

Iron and Steel Trades.—Business in the finished iron and steel branches of the trade of this district continues very quiet. There is no greater disposition to place orders than before the Easter holidays, and the fall of

Digitized by Google

prices has not been arrested. Locomotive builders are fairly well employed, and in the large establishments activity prevails. There is no change in the state of the agricultural machinery trade, and little improvement in the demand for cut steel and iron nails, prices remaining unchanged.

THE COAL TRADE.—The household coal trade since the holidays has been very active, and there is a good demand for shipping and steam coal. Gas coal is somewhat quieter. Engine coal of all qualities is also in less request.

SHEFFIELD, 8TH APRIL, 1891.

IRON AND STEEL.—There is no decrease in the demand for iron or steel for the manufacture of rolling stock. Tyres and axles continue to be ordered for both home and colonial railways, and manufacturers generally are fairly supplied with work. The question whether iron or steel is better fitted for axles is exciting much interest here. Local steel makers consider that steel is the better material. Steel is now made by the open-hearth process of an almost uniform quality, and capable of undergoing the most severe mechanical tests. Locomotive cranks have been in great demand for the past twelve months, and one firm in this district is turning out eight finished cranks each week. These cranks are guaranteed to run 100,000 miles, and are made of mild open-hearth steel. The propeller shaft trade is quiet at present, and there is little doing except a few three-throw solid forged cranks for the Spanish cruisers now being built. The armour plate mills are fully employed at present, and have sufficient orders to keep them going for some time to come. The recent tests of "all steel" and "compound" plates has left the whole question of their relative merits undecided, and further trials are anxiously awaited. Pig iron of all grades still shows a tendency to decline.

FUEL.—The output of coal from this district continues undiminished, and prices are fully maintained. In some cases colliery proprietors are obtaining in the open market double the contract price for their best coal. The best qualities of coke are firm in price, with no immediate prospect of a reduction. Smiths' washed coke is actively inquired for. Some simple method of eliminating the sulphur in this class of fuel is much needed.

THE MERCHANDISE MARKS ACT.—The Sheffield Federated Trades Council have secured a conviction against a Blackpool auctioneer for selling xylonite-handled knives as ivory.

INDUSTRIAL EXHIBITION.—An Industrial Exhibition was opened at Sheffield on the 28th ult. A marked feature of the Exhibition is the great variety of trades that are represented. In the Artisans' and Women's Industries Section a very good show is made of machinery models of all kinds. In the Iron and Steel Manufacturers' Section there are good exhibits of machinery and cutlery.

NORTH STAFFORDSHIRE, 8TH APRIL, 1891.

COAL AND IRONMASTERS' ASSOCIATION.—The quarterly meeting of this association was held at Stoke-on-Trent on the 6th inst. The reports relating to the present prices in the iron trade were rather unfavourable, and some anxiety as to the future was expressed. Sales were generally deferred until the meeting at Birmingham on the 9th inst.

COLLIERY EXPLOSION.—On the 3rd inst. a serious explosion occurred at the Sladderhill pit, belonging to the Midland Coal, Coke, and Iron Company, which resulted in the loss of ten lives and much damage to the underground workings.

THE POTTERY TRADE.—A meeting between the potters and their employés, held last week, seems likely to result in the reconstitution of the Conciliation Board and in a friendly settlement of the wages question.

BIRMINGHAM, 8TH APRIL, 1891.

GENERAL TRADE.—Trade generally is very quiet in this district, and there seems to be no sign of improvement. Wages and fuel are high in proportion to selling prices, but seem likely to decline before long. The general prices of manufactured goods are going down in anticipation, and if reductions in fuel cause a further depression in the prices of iron goods they will be unremunerative. The outlook is not cheerful, but it is hoped that workmen will agree to such reductions of wages as will enable employers to face the situation. The Midland Iron Trade Wages Board met last week and received the accountant's return of the average selling price of iron in January and February. The price was £6 13s. 7½d., and according to the sliding scale it should cause a reduction of 2½ per cent. in ironworkers' wages, but since wages had not been reduced in the North of England the employers decided not to press for the reduction. Sheet iron is quoted at £8 per ton.

MESSRS. W. & T. AVERY.—This business, carried on by Messrs. J. & Henry Avery, is being transformed into a limited company. The works have been much extended of late, and are well employed. The capital is £200,000.

LEICESTER, 8TH APRIL, 1891.

COAL MINING.—Considering the period of the year a very fair business is being done. Railway companies are beginning to make contracts, and this has considerably strengthened the prices of steam coals, which are also in good demand. In most household coals there has been a fall of about 6d. per ton. Most of the collieries are making very fair time, and stocks are generally small. The prospects of this district are cheerful.

WOOL SPINNING AND YARN TRADES.—Since the holidays the local wool market has assumed a more cheerful tone. The feeling prevails that the lowest prices have been touched, and the tendency of the market is towards a rise. Staplers, finding stocks cannot be replaced on better terms, do not press for business, and hold out for a fractional increase. Choice lots of short fleeces are scarce, but buyers only venture to supply pressing wants and resist the attempt to obtain better prices. Spinners have resumed work, and a fair amount of business is being done. In fancy yarns there is a brisker demand, but cashmeres and lambswools are quiet.

SWANSEA, 8TH APRIL, 1891.

TINPLATES.—There is much activity at all the works, mostly on contracts which terminate between the end of May and June, but it is difficult to form any idea as to the future of the trade. The tin bar makers declare that the present price of £5 per ton for Bessemer, and £5 5s. for Siemens bars, is unremunerative, and yet no contracts of any importance are heard of at these prices, which, with tinplates at 17s. 6d. to 18s. per box for common sizes, should leave a good margin to the makers. No improvement is looked for before the 9th inst., when the various members of the trade will meet in Birmingham. The pig iron makers are also complaining that neither iron ore nor coke can be obtained at a price to yield any profit, so that a considerable fall in the price of tinplates is not unlikely. The disorganised condition of the Tinplate Workers' Union makes submission probable if the masters should feel obliged to make a reduction in wages.

COPPER.—At the end of February the stocks of copper ore remaining unsold amounted to 6,366 tons, but they had already decreased to 3,239 tons in the third week of March. The total stocks of Chili copper produce—viz., ore, regulus, copper, and precipitate—remaining unsold on the dates named were equivalent to 5,286 tons and 4,900 tons of fine copper respectively.—We regret to announce the death of Mr. John Cady, who, for about twenty-five years, managed the Morfa Copper Works, until they passed out of the hands of Messrs. Williams, Foster, & Co. a few years ago, when he took charge of Mr. Dillwyn's spelter works.

LARGE TEMPORARY BUILDING.—The designs of Mr. Edward Bath, architect, Swansea, have been accepted for a pavilion to accommodate some 15,000 people during the forthcoming Eisteddfod. The building will be oval in shape, the main structure being 220ft. by 180ft.

BARROW-IN-FURNESS, 8TH APRIL, 1891.

HEMATITE.—There is less business in hematite pig iron this week. Prices have gone down further to 47s. 1d. per ton for hematite warrants, and makers are compelled to ask 49s. to 50s. per ton for mixed Bessemer numbers net f.o.b., although the value of iron ore has been reduced to 10s. to 10s. 6d. per ton net at mines for ordinary qualities, and although coke has at last come down 2s. per ton to 18s. 6d. to 20s. 6d. for East Coast qualities delivered at West Coast furnaces. The decrease in stock this week was 6,210 tons; the aggregate of stocks now amounts to 178,889 tons. Forty furnaces are still in blast.

STEEL.—A quiet tone prevails in the steel trade, but makers in the Barrow district are fairly supplied with orders. In West Cumberland, however, the reverse is the case, and the mills in some cases are stopped. There are a few orders offering for rails, and heavy sections are done at £4 10s. to £4 12s. 6d. per ton. Steel shipbuilding material is not in brisk demand, but makers are fairly supplied with orders, and expect new contracts.

SHIPBUILDING.—A great blow to the prosperity of the shipbuilding and marine industries of Barrow has been received by the death of Mr. Bryce-Douglas, the managing director of the Naval Construction and Armaments Company, Limited. His was a useful life, and gave promise of great things for the future. He raised shipbuilding in Barrow from absolute inactivity to its present great prosperity.

MIDDLESBROUGH, 8TH APRIL, 1891.

PIG IRON.—The quarterly meeting of the iron market, held yesterday, was well attended, but no improvement in business was reported in any direction. Buyers will not buy iron, as they expect to see prices go down still further; indeed, the prices of pig iron were almost 1s. per ton less than on the previous market day. It is difficult for some of the ironmasters to make No. 3 pig iron at less than 43s. per ton, and it is therefore not surprising to hear of more furnaces being blown out. At the Thornaby Works, South Stockton, a furnace is to be blown out, and it is probable that one will be blown out at the Newport Ironworks. Merchants are quoting 38s. per ton for prompt f.o.b. deliveries of No. 3 G.M.B., but some makers are getting more for iron for the Continent, which could not be had from second hands. Middlesbrough warrants are 37s. 10d. cash sellers and 37s. 9d. cash buyers, but in the absence of actual business these prices are only nominal. Grey forge pigs, which are in smaller consumption, both locally and in Scotland, are obtainable at 37s. 3d., and even 37s. would not be refused by some sellers. Local hematite is 51s. per ton for mixed numbers, but some sellers would not accept orders under 52s.

COKE.—The tendency is downward in coke prices, and it may be had for 13s. 6d. per ton delivered at furnaces.

SHIPMENTS.—The shipments of pig iron from Middlesbrough this month are very poor, being only 11,108 tons, against 16,700 tons to 6th March and 21,048 tons to 6th February. This is, however, partly due to the bad weather delaying steamers at sea.

MANUFACTURED IRON AND STEEL.—The prices of finished iron and steel are weak, but competition is keen among manufacturers. The Darlington Iron and Steel Company have paid off some 300 hands, but they will be taken on again after some repairs are completed if orders come in. Prices are as follow:—Common bars, £5 12s. 6d.; best bars, £6 2s. 6d.; best-best bars, £7 2s. 6d.; iron ship plates, £5 12s. 6d.; steel ship plates, £6 2s. 6d.; iron boiler plates, £6 12s. 6d.; iron ship angles, £5 10s., all less 2½ per cent. on trucks at works. Heavy steel rails are £4 12s. 6d. net at works.

IRONMASTERS' RETURNS.—The return of the Cleveland Ironmasters' Association for the month of March show that there were 94 furnaces blowing, as against 97 in February and 105 in March last year. The make of pig iron of all kinds was 226,544 tons, an increase in February of 15,362 tons. The stocks held by makers and in public stores were 289,986 tons, an increase for the month of 2,645 tons.

WORK AND WAGES.—At a meeting held to-day of the members of the Cleveland Ironmasters' Association and representatives of the blast furnacemen, the latter agreed to accept the sliding scale on the old basis. At the former meeting the masters demanded 12½ per cent. reduction or a return to the sliding scale which regulated wages up to the end of June last year. The men were in favour of a return to the sliding scale, but wanted certain concessions which the masters refused. The official ascertainment of realised prices for the past three months shows the net average selling price of pig iron to have been 43s. 2 37d., as against 47s. 7·65d. during the previous quarter. This gives a reduction of about 4 per cent. on the present rate of wages.

NEWCASTLE, 8TH APRIL, 1891.

THE IRON TRADE.—The finished iron trade shows no signs of briskness, and only for a few special products is there a good demand. In spite of the unsatisfactory state of business generally, Messrs. Raine & Co., of Winlaton Rolling Mills, appear to be confident of the future, and will, in the course of the present month, open new works in the neighbourhood of Dunston.

THE COAL TRADE.—The shipments of coal and coke at Tyne Dock for the week ending the 4th inst. amounted to 86,809 tons, being a decrease, as compared with the shipments for the corresponding week last year, of 1,345 tons.

SHIPBUILDING.—The outlook in the shipbuilding industry becomes more discouraging as the season advances, and at several establishments large numbers of men are being paid off each week. Some firms are busily completing their last orders, and in these cases there is no immediate prospect of any further contracts being secured. Shipowners who contemplate additions to their fleets are holding back for a further fall in builders' quotations, and, so far as home orders are concerned, very little business is expected to be done during the next few months. It is probable, however, that some foreign orders of importance will shortly be placed with Tyne builders, and one leading firm is at present negotiating for the building of two very large steamers for Russia. Two oil-carrying steamers of large tonnage are in course of construction at Messrs. Armstrong, Mitchell, & Co.'s Elswick yard, and it is understood that they are ordered by German owners. The yards of Messrs. Palmer at Howden and Jarrow continue very busy with the Government contracts now in progress.

ENGINEERING.—The whole of the marine engine works keep fairly busy, as the contracts taken last year are not yet completed. In locomotive establishments business is also good, and one or two good orders have recently been received. By a recent arrangement Mr. W. F. Snowdon, of 32, Side, Newcastle, has become the sole vendor of Bell's Asbestos Company's manufactures, in the counties of Northumberland, Durham, Cumberland, and Westmoreland. Mr. Snowdon has, in consequence, extended his warehouse accommodation.

DUNDEE, 8TH APRIL, 1891.

JUTE AND FLAX TRADES.—From a compilation showing the shipments of jute from Calcutta for the last three years, during the season extending from 1st August to 28th February, it appears that the number of bales exported last season was 2,195,588. In the previous season the export was 2,057,733 bales, and in 1888-89 it was 2,147,086 bales. Although the totals do not show much change, the figures bring out some interesting facts with reference to the distribution of the exports. Comparing the exports for the season 1890-91 with those for the season 1888-89, we find that London has taken 412,468, as against 618,085; Liverpool 13,376, against 17,617; and Barrow 12,450, against 25,646. On the other hand, the exports to Dundee have increased from 1,041 622 to 1,060,864, those to the Continent from 355,249 to 573,014 and those to America from 88,867 to 123,016 bales.

(*For description see page* 344.)

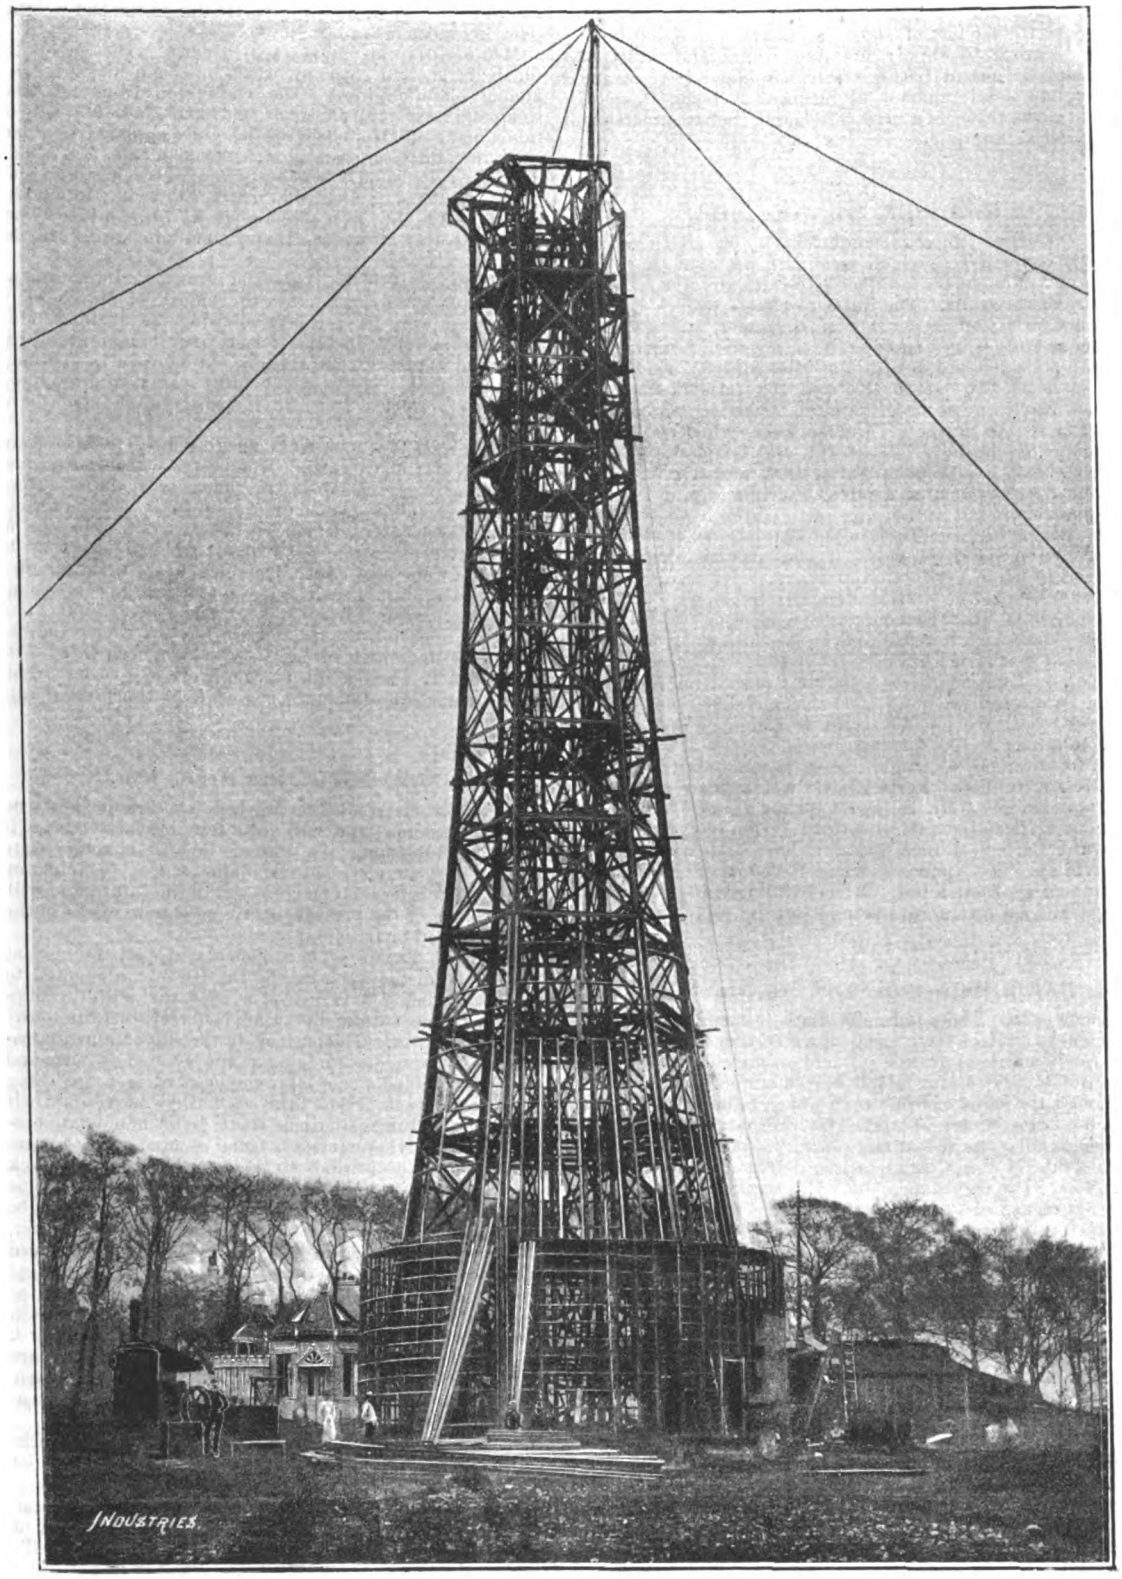

FIG. 4.—VIEW OF MODEL OF EDDYSTONE LIGHTHOUSE DURING CONSTRUCTION.

THE INSTITUTION OF CIVIL ENGINEERS.

AT a meeting held on the 7th inst., the President, Sir John Coode, K.C.M.G., being in the chair, a paper was read on "The Cost of the Generation and Distribution of Electrical Energy," by Mr. R. E. B. Crompton, M.Inst.C.E. Machinery for the supply and distribution of electrical energy came under two heads—namely, the generating plant, comprising boilers, steam dynamos, and switching apparatus, and the distributing plant, consisting of a network of conductors, supplemented in some cases by accumulators, and in other cases by transforming apparatus to change energy from high pressure to low pressure.

Cost of Generation.—With the high efficiency of 96 per cent., which was now attainable in dynamos, the cost of the electrical energy ought only to be a small fraction in excess of that of a corresponding amount of mechanical energy. The wide difference between the calculated amount and the figures attained in practice were considered. The three items of cost—namely, material, labour, and up-keep—were influenced chiefly by the "load factor," the design and arrangement of the plant, and the local cost of material and labour. The author had given the name of load-factor to the relation which the actual output of any given plant bore to what would be its output if it were worked continuously at the full load. In order to compare the relative economy of fuel, water, or other material used in generating electrical energy, he had fixed on a consumption of 25lb. of water and 2½lb. of Welsh coal per unit generated as a standard which might be reached in the future, although nothing approaching those figures had yet been attained in practice.

The author proceeded to describe the electrical supply stations from which the data for the paper had been obtained—namely, the Kensington and Knightsbridge Electric Lighting Company and the St. James's and Pall Mall Electric Lighting Company. The load-factor of these stations varied from the exceedingly low figure of 2·5 for the Kensington Station in the month of August to 41·5 on one occasion, which was the best load-factor of the St. James's and Pall Mall Company's station, and showed how these varying load-factors affected the cost of productions. It was pointed out that a limited use of storage plant could reduce the consumption of fuel, &c., and shown by a diagram that the proportion of accumulators should be about 20 per cent., or one-fifth of the whole generating plant. The author recommended a return to the older type of internally fired boilers; the chief cause of the small evaporation in low load-factor stations was the loss of heat incurred in getting up steam in several boilers for only short periods every evening. Several types of boilers which had been found to have special advantages were described, one important consideration being that in electric light stations the space from front to back was frequently limited, so that a boiler which could be built up to a height of from 14ft. to 16ft. offered several advantages.

Distribution.—The cost of distributing electrical energy was made up of that of the up-keep of the distributing plant and of the percentage of the energy which was lost by the fall of pressure in the conductors. It followed that the merit of competing systems was inversely as the cost of generating the units so wasted divided by the up-keep of the conductors. For instance, if in distributing 20,000 units to a given distance system A wasted 1,000 units in a given time, the cost of up-keep for the same time being £10, whereas system B wasted 3,000 units at a cost of up-keep of £3, B was slightly better than A, because $\frac{2000}{10} : \frac{1000}{3} :: 300$ to 333. It was difficult to apply the method of comparison to the systems now in use, as the cost of up-keep was not yet known with sufficient accuracy. The author's opinion was that whenever underground mains consisted of continuously insulated cables, the sum required for up-keep would be not less than 4 per cent. of the original cost, and was not likely to exceed 7 per cent. When, however, the underground mains took the form of bare copper conductors with glass or porcelain insulators the cost of up-keep might be as low as from 1 to 2 per cent. A table given showed the load-factors for the Chelmsford station for the months of August and December, 1890, and a twenty-four hours' load-diagram, taken on the 20th of January, 1891, was exhibited. The annual load-factor was found to be 31·0, and the pounds of coal per unit generated, 8·88; the pounds of coal per unit delivered, 10·70, hence the efficiency reached 83 per cent. But this was an extremely favourable example, and an alternating-transformer installation in a medium-sized private house in the Kensington district, tested by Professor Ayrton, was found to have a mean annual efficiency of only 53 per cent. The remedy for this defect in the alternating system consisted in what had been called "banking" the transformers. This meant that a district to be supplied with electricity should be laid with a low-pressure network, in all respects similar to that provided for the direct low-pressure system; but in place of the feeders, and at the point where the feeder-mains were connected to the network, a fireproof and incombustible chamber should be formed under the surface of the roadway. In this a number of transformers of graduated sizes were arranged, with the high-pressure mains connected to them, so that the transformers might be switched into action automatically as required—that was to say, during the hours of light load the smallest only would be in action, the others being automatically added as the demand increased.

Summarising his experience, the author endeavoured to show:—

1. The actual cost of generating and distributing electrical energy on the scale at which it was now produced, and with the machinery that was already installed.

2. The direction in which improvements might be introduced to secure greater economy.

3. The important effect of a variable load-factor, which might be almost entirely eliminated from the cost-sheets of those who desired to employ electrical energy continuously.

4. That the losses on distribution in low-pressure supply were already so low that further improvement could not be expected.

5. That the existing systems of alternating supply would have to be greatly modified if they were to be used in residential neighbourhoods having low load-factors.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 10TH APRIL, 1891.

AMERICAN WARSHIP DESIGN.

IN our issue of the 27th ult. we indicated some of the features which were likely to be found in the ships of the future, especially in those designed for passenger and cargo traffic. But not less interesting and important from a scientific point of view are the probable developments of the ships of war in so far as these can be recognised in the vessels which are now being built by the leading Powers. The paper recently read by Mr. Biles on "Some Recent Warship Designs for the American Navy" was of great value from this point of view. When the Americans first began to build ironclads, under the inspiration of men like Stevens and Ericsson, the designs were of great originality, and, although the vessels were deficient in speed, they were, nevertheless, formidable instruments, both of offence and of defence. At the present time the American authorities seem to be content to follow our lead. As Mr. White has remarked, all the details of our warships are obtainable for a few pence from the Parliamentary returns, and many of the points in American ships are copied directly from those of the British Navy. The American Naval Department systematically carries out its method, which consists in obtaining the details of all foreign ships, analysing them, and then producing rival designs. They even invite foreign naval architects who have had experience in warship design to send in plans, and those of the "Texas," for instance, were supplied by the late Mr. John, while the "Baltimore," "Philadelphia," and "Charleston" are from designs supplied by Mr. White. Our cousins seem, however, to be in great part at least able now to do their own work, for Mr. Biles expresses the opinion that American ship designers and builders have shown that they are capable of producing vessels quite equal to their promises, and at least equal to the best European practice. Mr. White also stated that they not only have begun to build the ships themselves, but they also produce all the materials necessary for their manufacture. Hence they are likely to produce results that will compare with or even rival ours. These are important facts to be borne in mind by our shipbuilders in considering the designs of the ships which are now being built for the American Navy, and also on account of their bearing on the probable future of the shipbuilding industry in this country.

The American Naval authorities, feeling no doubt how much they owe to foreign naval architects, are willing to give the fullest information with regard to their own operations and the designs they are carrying out. As to the designs, although there might not be very much in them which the Americans could call original, still they embody many of the leading features of the most modern European ships of war. Mr. Biles' paper will be found exceedingly useful, as it gathers up the many details in a compact form, and gives suggestions as to the future. The Secretary of the American Navy not only gave all the information which was wanted, but stated that he courted the fullest criticism, and hoped that it would not be confined to commendations. We should, therefore, be glad to have the the opinions of some of our readers concerning these war vessels.

The keel of the first modern American warship was laid in 1883, and a glance at the figures we gave on page 291 of our issue of the 27th ult. will show that the progress made has been great, if we measure it by the difference between the "Chicago" and the "Baltimore." These vessels are of practically the same displacement, though the "Baltimore" has a smaller main battery, having only 10 guns, against the 14 of the "Chicago." Her speed is, however, more than 3 knots greater than that of the "Chicago," and she has a protective deck 2½in. thick on the flat, and 4in. on the slope. The "Philadelphia," which is a sister ship to the "Baltimore," attained a still higher speed; and the "San Francisco," which is a little over 4,000 tons displacement, attained a speed of over 20 knots, while the "Newark," a sister ship to the "San Francisco," has attained a speed of 20·4 knots. With regard to the workmanship of the "Newark," Mr. Biles stated that he carefully inspected it at the yard of Messrs. Cramp, Philadelphia, and he feels sure that it is quite equal to our best shipbuilding practice. There are no vessels in the British Navy which can be closely compared with those named, as during the period 1883–87 the cruisers built in this country were either belted, and therefore larger and more costly for the same fighting power, or, if of the same type, smaller and slower. The recently published Navy Estimates of this year, however, give some particulars of eight vessels of 4,360 tons displacement about to be built, which are to have forced draught speeds of 19½ knots and a coal supply of 400 tons, and in dimensions and speed are very similar to the American ships. We may mention that the trials of the American ships were made at load draught and with the boilers working under forced draught, and the speed is a mean of four hours' run, two with and two against the tide, the speed of the tide being carefully measured at several points on the route by boats stationed for that purpose. One of them, however, the "Baltimore," has, since her trial, been on a long cruise, and has shown herself to be a good sea vessel. She steamed from New York to Stockholm at a speed of about 11 knots without stopping to coal, and she could have steamed 1,500 knots further at the same speed with the coal that she actually carried. After the spurt made in 1883, it was not until the end of 1889 that it was decided to make any important additions to the American Navy, but there are now under construction seven cruisers and seven armoured ships, with considerable variety of design. In the matter of armour, guns, engines, and general plan, the most effective vessels in European navies have been carefully studied, and their best points utilised and put into a very compact form. The coast line battle-ships are the most important in the programme, and they have been designed, to use the words of Mr. Theodore Wilson, the Chief Constructor of the United States Navy, "to be able to fight vessels carrying the heaviest guns and armour," and by inference comparison with our most recent battle-ships cannot fail to be courted. Among the cruisers there is one to which we would direct special attention, and that is "No. 12." She is called a "Commerce Destroyer," and is popularly known as the "Pirate." She is intended to have a sustained sea speed of 21 knots. Mr. Secretary Tracy thinks this "vessel absolutely without parallel among the warships of the world, and that the combination there made unites a sufficient arma-

Digitized by Google

ment with complete protection against light guns, while at the same time the vessel will have a sea speed and a coal endurance hitherto unknown in ships of war. No merchant vessel that she meets, armed or unarmed, can escape from her." From her design she seems likely to meet these expectations, as she has ample power, sufficient armour, and guns and torpedoes which would quickly dispose of any merchant ship. The vessel is well devised, and would give a good account of herself against most cruisers. She is, however, designed to avoid the enemy's cruisers, her function being to catch and destroy the merchant steamers of an enemy. She would not hesitate to fight and try to destroy any of our merchant ships fitted as cruisers. Mr. Biles remarks that the building of such a vessel is certainly an indication of American skill, both in conception and construction, and he remarks that whether vessels specially designed to meet this one, or an improved type of mail steamers, should be adopted as the best means of protection, is a question worth some consideration. There are several other very interesting vessels built, or intended to be built, for the American Navy, but into a description of these our space will not allow us to enter.

The activity and originality shown in connection with the recent development of the American Navy affords material for thought, not only to our shipbuilders, but also to our statemen. Notwithstanding this activity we sincerely hope that the two great English-speaking nations of the world will never disgrace civilisation by going to war with each other. We may say, frankly, that we should have preferred to see America content in developing her industrial and mercantile resources. Since, however, she seems determined to take a position as a naval Power, it is the evident duty of our statesmen to make themselves thoroughly acquainted with American naval progress, and to take steps to guard against possible contingencies.

INSURANCE OF SCOTCH MINERS.

Another of those signs of the times now becoming very common, and all pointing in the same direction, is the Bill introduced into the House of Commons by Mr. Baird, and other Scotch members, to provide for a national system of insurance against accidents in mines of all kinds in Scotland. The preamble of the Bill states that those employed in the mining industry in Scotland are liable to serious and fatal accidents, by which large numbers of persons or their families are often left without the means of living, except by the aid of the poor rates or by public charity, and that, therefore, it is desirable to make obligatory the practice which has prevailed among some of the largest English colliery owners and their workpeople of making provision against accidents by insurance, effected partly by payment out of wages, and partly by contributions from the mine owners. The Bill proposes the establishment in each of the two mining inspectors' districts in Scotland of an insurance fund, to be administered by a Board consisting of three representatives of each of the parties concerned—namely, the landlords or lessors of the mines, the lessees, and the miners, together with H.M. Inspector of Mines for the district. Each year the two Boards are to meet and to agree upon a scale of contributions and allowances, which shall have been previously fixed by three salaried assessors. No person is to be employed unless he is insured, and kept insured, during the continuance of his employment. If a mine owner employs men who are not insured he will be liable, in case of accident, to pay to them or their relatives the same amount he would have had to pay if the men had been insured, so that it will be to the interest of each employer to see that all his workers are insured. The employer may also deduct the landlord's contribution from the amount of his royalty. For the purposes of the insurance fund the employer and the mine owner are each to contribute ¼d. per ton per annum, while the workmen are, if employed underground, to pay 2d. per week; if on the surface, 1d. per week, with half these sums in case of persons under 16 years of age. Any contributions in arrear from the owners and lessees are to be recovered as an ordinary debt, and are to be paid into a common fund. No person can contract himself out of the Act, and no payment from the insurance fund is to be taken into account as mitigating damages recoverable under the Employers' Liability Act. In the schedule attached to the Bill the following scale of allowances and payments is given, namely:—For disablement—full members, for the first week 5s., and afterwards 10s. per week, with half the above sums to half-members. Funeral allowances—married members, £5; unmarried members, £20; half-members, £5. For a widow, during widowhood, 7s. 6d. per week; and for children, until they attain the age of 14, as follows:—For one child, 2s. 6d. per week; for the second child, 2s.; for the third and remaining children, 1s. 6d. each, while the amount to be given to dependent relatives is to be fixed by the Board.

The general principle involved in the Bill is one which will require very careful consideration, for if it once be applied to miners, there are no reasons why it, or something like it, should not be applied to other industries. Moreover, there are many of the details which will require to be very carefully examined, and we take it that they will be so examined by those who represent the interests of the three parties concerned.

MINING STATISTICS FOR 1890.

A Blue Book has just been published, giving summaries of the statistical portion of the reports of Her Majesty's Inspectors of Mines for the year 1890. From this it appears that the number employed in and about all the mines, exclusive of those employed on private branch railways and tramways, and in washing and coking coal, amounted to 655,287, of whom 5,599 were females, the aggregate increase during the year being 48,132. The total number of fatal accidents was 899, and the total number of deaths occasioned thereby 1,206, being a decrease of 13 in the number of fatal accidents and an increase of 78 in the number of lives lost, compared with the totals of the preceding year. There was one death for 543 persons employed, as compared with one for 538 in the preceding year. The total quantity of mineral wrought in the different districts was 194,605,887 tons, of which 181,614,288 was coal and 8,117,476 ironstone, the rest being fireclay, oil shale, and other minerals, making a total increase of 4,972,231 tons compared with the preceding year. There was an increase of 4,697,564 tons of coal, but a decrease of 153,066 tons of ironstone. The output of coal last year shows an increase of nearly 53 million tons over that of 1873.

Some interesting information concerning the ratios of the fatal accidents and the deaths to the number of persons employed in and about the mines under the present and former Coal Mines Acts is given for the periods covered by the first three Acts, and in detail, with averages since 1872. From these we see the great increase of safety in the occupation of miners during the operation of these Acts, the average ratio under the first Act being one death in every 233 persons employed, under the second Act one death in 258, under the third Act one death in 312, under the fourth Act one death in 466, while for the past year it is one in 528. A table of the hours of the deceased persons' shifts in which the fatal accidents happened shows that in only five cases had those to whom the accidents occurred worked more than twelve hours. The total number of persons employed under the Metalliferous Mines Regulation Act was 42,054, of whom 1,393 were females employed above ground. There were 38 fatal accidents and 46 deaths, the number of accidents being 26 less and the number of deaths 18 less than in the preceding year. There was one fatal accident for every 1,106 persons employed, and one death for every 914 persons employed, which are more favourable ratios than in any preceding year.

COST OF CENTRAL STATIONS.

A paper on this subject was read before the Institution of Civil Engineers by Mr. Crompton last Tuesday. We publish an abstract in another column. Mr. Crompton has always been a great advocate of the publicity of central station figures, and he acts up to his precepts by publishing the figures of his own stations as fully as possible. It is greatly to be wished other engineers would follow his example. A station in London cannot be the trade rival of a station in Manchester, so that the withholding of information is futile. If the two stations were to compare notes they could select what is good and reject what is bad in each, and thus they would largely increase the business of both. The electric engineering industry has been a good deal hampered by secresy. In incandescent lamp making each maker kept his processes to himself rigidly. Dynamo designing was regarded as an erudite mystery till it was popularised, chiefly by Mr. Kapp. Cable making is a profound mystery even now. Transformer design was kept back, not by secresy, but by the publication of elaborate but useless formulæ, which do not fit in with the facts. There is now, however, the greatest uncertainty as to the real first cost of various systems of distribution, and as to the efficiency and cost of running, and the sooner actual facts are made public the sooner will electric lighting be on a sounder basis.

THE LATE MR. BRYCE-DOUGLAS.

We greatly regret to have to record the death of Mr. Archibald Douglas Bryce-Douglas, which took place at his residence at Ardrossan, Ayrshire, on Sunday last, after a week's illness. He came down to the Clyde in the new steamer the "Empress of Japan," one of the fleet of vessels built by the Barrow Naval Construction and Armaments Company for the Canadian Pacific Railway Company, and on the passage was seized with illness. He was, however, able to proceed to his residence at Ardrossan, but his illness rapidly developed into peritonitis, and ended fatally. He was a man of vigorous physique, but for some months past he had not been in his usual health.

Mr. Bryce-Douglas is another notable example of what can be done by force of character and natural abilities, rather than by systematic training, for of the latter he received comparatively little. He was the son of the Rev. John Bryce, the parish minister of Ardrossan, and, having been born in the year 1840, was at the time of his death only 50 years of age. Like many other Scotch youths his father destined him for the ministry of the Scotch Church, but as he grew up it soon became evident that his vocation lay in an entirely different direction. After serving a two years' apprenticeship with a local joiner, he went to Glasgow, and entered the engineering establishment of Messrs. Randolph, Elder, & Co., then situated in Centre Street. He gained much experience there, and attracted the attention of Mr. Charles Randolph, who soon perceived the great natural abilities of the young man. But the spirit of adventure was strong within him, and after a few years in Centre Street he went as a passenger in a sailing vessel to Auckland, where he had the promise of an appointment to take charge of an important machinery plant. The carpenter died during the voyage, and Mr. Bryce was offered and accepted the position thus rendered vacant.

On arriving in New Zealand the Maori War had just broken out, and, taking the situation in at a glance, he soon found an opportunity of working his passage, with a well-known captain of one of our ocean liners, to the Pacific Coast. For about a year he was in the service of the Peruvian Navy, at the end of which time he was offered, and accepted, a situation as a sea-going engineer with the Pacific Steam Navigation Company, and thus formed a connection which may be said to have terminated only with his death. In the year 1865 he revisited Scotland, and after spending a few months with his friends, and successfully undergoing his examination for "extra first-class" engineer, he returned to Callao to become assistant engineer of the Pacific Company. This position he occupied till 1869. In that year the headquarters of the company were removed from the island of Tobogo, in the Bay of Panama, to Callao, on the establishment of a line of steamers to sail direct between Liverpool and Valparaiso. A vacancy took place at the same time in the office of the superintending engineer, through the resignation of Mr. Jamieson, and Mr. Bryce received the appointment, which he held for a period of six or seven years. On his way home an incident occurred which was an index of the character of the man. A small coal-laden vessel had stranded in the Bay of Panama. He took with him from Callao a staff of men and the necessary appliances with the view of raising her. On arriving in the bay, he learned that the "Tagus," one of the Royal Mail Company's steamers, had gone ashore near Colon. Unable, on account of the heavy sea, to accomplish the work which he had come to do, he crossed the isthmus with his staff and appliances, and successfully carried out the more difficult task of raising the "Tagus." The other vessel was also raised in due course, Mr. Bryce not only directing, but taking an active part in working in the diving bells and repairing the hulls, his fertility of resource being displayed on the occasion by the employment of a locomotive to work the pumps.

On his return to this country, Mr. Bryce resumed his connection with the firm from whom he had received his early training, the works having been removed from Centre Street to much larger premises at Fairfield. When Dr. Kirk left the firm to become senior partner with Messrs. Robert Napier & Sons, Mr. Bryce became the head of the engineering department at Fairfield, which was then carried on under the name of John Elder & Co., although Mr. John Elder had died some years previously, and Mr. (afterwards Sir) William Pearce was its leading spirit. The years that immediately followed were probably the most important in the history of the

Digitized by Google

undertaking, for during that period there were turned out the "Arizona," the "Alaska," and the "Oregon." The great revolution which took place at that time in ocean-going steamers owed much to Mr. Pearce and Mr. Bryce-Douglas. About this time the latter had added the name Douglas to that of Bryce, on succeeding to a small landed estate in Ayrshire. Besides the engines for the Cunard liners, Mr. Bryce-Douglas constructed several sets for the Orient Line and for foreign ships of war, in addition to many for ordinary merchant steamers.

In 1888 he accepted the position of managing director of the Naval Construction and Armaments Company, which took over the works of the Barrow Shipbuilding Company, and he soon introduced new life into that concern. Important contracts were secured from the Pacific Steam Navigation Company, the British African Steam Navigation Company, the Canadian Pacific Railway Company, and the British Admiralty. The latter included three second-class cruisers, all of which have been launched, and one—the "Latona"—has been delivered. The work for the Canadian Pacific Company included three high-speed 6,000 tons steamers, for the service between Vancouver and Japan and China. The pioneer ship, the "Empress of India," is now on her first voyage; her sister ship, the "Empress of Japan," ran most successful trials last week; while the third, the "Empress of China," was launched a fortnight ago. There are at present in the yard many ships of different sizes and types. It is understood, moreover, that negotiations are well advanced for the building of four fast steamers for a new line from England to Canada, which are intended to cross the Atlantic in five days. In all these projects Mr. Bryce-Douglas was the leading spirit, and it will be very difficult to fill his place at Barrow.

It is somewhat remarkable that many of those who took active parts in the Fairfield Works should, like Mr. Bryce-Douglas, have died in the prime of life, and just when they were in a position to do their best work. Mr. John Elder, Sir William Pearce, and Mr. John Jamieson were all comparatively young men at the time of their deaths. The burden of such large concerns, falling as it generally does on the shoulders of one or two persons, would seem too great for even the strongest of men.

The funeral took place on Wednesday, and, according to the expressed wish of Mr. Bryce-Douglas before his death, was strictly private, the relatives, trustees, a few neighbours, and representatives of the Barrow firm and Canadian Pacific Railway Company comprising the funeral *cortège*.

Letters to the Editor.

ENGINEERS IN THE ROYAL NAVY.

To the Editor of "Industries."

Sir,—It is encouraging to see that the country is waking up to the fact that some improvement will have to be made in the engineering branch of the Navy, as is shown by the article in *Industries* of the 27th ult., with many of the statements in which naval engineers will agree. But it is evident that the writer has not had much practical experience of the Royal Navy, and without such experience it is almost impossible for anyone to thoroughly appreciate the conditions of that service. As it is important that the country should be in a position to pronounce an intelligent judgment on the question, I would ask for a little space in which to point out some facts which would probably somewhat modify one or two of the views expressed by the writer.

Perhaps the principal point is that referring to educational requirements. The writer states that a fault of all the Admiralty examinations is that they are conducted by men who are good mathematicians, but not as a rule engineers. Well, the person who is principally responsible for the extent of the examination is the Engineer-in-Chief—the late one, Mr. Sennett, now of Messrs. Maudslay's firm, who is referred to in the article, and the present one, Mr. Durston. If these two are not engineers, where shall we find any? But perhaps it may be thought that their responsibility is only nominal; if so, a great mistake would be made, for, though they may not have personally worked at all the details, yet these have only been entrusted to gentlemen who, it cannot be denied, are good mathematicians, but who, at the same time, are most decidedly engineers, if long training and hard work at their profession can make them so, and over the results of the whole the Engineers-in-Chief have exercised a decidedly close control.

The fundamental idea of the writer, and one which I would venture to decidedly dispute, is that the work of a naval engineer is comparable to that of an engineer of the merchant service. This appears in speaking of the "artificers" also. Now an artificer is a workman pure and simple. It is said that if he go into the merchant service he can become manager or superintending engineer, while in the Navy he remains an artificer. With regard to the first statement, perhaps my acquaintance with the merchant service is not sufficient to enable me to speak with authority, but I have a shrewd idea that to get into, say, the P. and O., the Cunard, or the White Star Companies, requires something more than a knowledge of workshop practice; this something more does not, perhaps, take the form of mathematics or physics, though such things as "extra firsts" are fairly well competed for, but there it is. At the present time I should say the chances of an ordinary workman ever becoming much above first engineer of an ocean tramp are rather limited; I am here, however, open to correction. But certainly the workman will not do for the Navy; hard experience tells us this, and we have been through the whole thing.

The original naval engineer was the man of workshop practice and little else, and necessity has driven us to our present state. In the first place, take the cream of the merchant service, the "big liners," what has the chief engineer to do? Simply to drive his engines as hard as he can from port to port. When he comes home he is at once in the hands of the superintendent. At sea his staff go below in turn to take their watch with the one object in view of keeping the engines going, and, their watch over, take their rest till the next one. On the other hand, the chief engineer of a battle-ship has delivered to him a ship, of which the actual propelling engines will probably be almost his least trouble; she is crammed from stem to stern with machinery; the very air for the men to breathe and water to drink he must supply; the hull is in his charge in conjunction with the carpenter; electric lights, as no electrician is carried; torpedoes; gun mounting, and the hydraulic gear for working them; in some cases the workshop necessary would make quite a respectable factory on shore; and, besides this, he has delivered to his care the welfare of some hundred or more men. All these he is responsible for during a period of three or four years. True, he may go to a dockyard during that time—but woe be to him if his list of defects should be considered too big!—and during that time the whole has to be kept in perfect order and readiness at every moment, *as a fighting machine*. I italicise these words because it often appears when critics, and some even belonging to the Navy, are writing, as if they forgot this fact. A good pair of legs and the ability to use them were, I believe, considered of use in the now defunct prize ring, but I do not think it was customary to cry down a pugilist because he took longer over a hundred yards than a champion sprinter, yet it has always appeared to me exactly a parallel case when certain gentlemen dilate so persistently on the speed at which the "City of Paris," &c., can run as compared with our warships.

Now it is as certain as anything can be that to be able to carry out the duties I have stated, and to carry them out in conjunction with other officers, the naval engineer must be an educated man, and it is for this reason that the Admiralty institute the examination. It will not, I suppose, be contended that a man cannot be both a mathematician and an engineer. If it be so, then I say that the present engineer officers are a direct proof to the contrary. Some few, perhaps, may consider the drudgery of their profession somewhat beneath them, and these get noticed, and so a false impression may be created; but these even are not so useless as many imagine, and instances have occurred in which such men, by the command they have obtained over their subordinates, have carried out their duties in a thoroughly efficient manner, and it is here that education often tells. I would not, however, be understood as expressing approval of this, and the instances are few, and, speaking generally, I may say that the blackest, filthiest looking figures I have at times come across in the interiors of boilers, bilges, and other secluded retreats have been the men of the highest mathematical attainments.

With regard to the approval expressed of the institution of competition, it hardly appears to agree with the remainder of the paragraph, unless it is assumed that the grievances mentioned in the commencement will be remedied, and if this is to be done the remedy lies in the hands of the profession outside by religiously ignoring these competitions until it is done. It is doubtful, however, whether this is a good step or not. The Navy is a peculiar service—how peculiar is only known to those in it—and personally I think that a really good naval officer must have been caught young; also he should have commenced as an officer. This clashes with your views as to the artificers, but, although I wish it were otherwise, it is, I am afraid, a hard fact.

The case of Mr. Sennett leaving the service is mentioned, and I may mention that his is not an isolated case, the following names coming to my mind now:—Mr. Seaton, of Earle's; Mr. Spence, of Newcastle; Mr. Milton, of Lloyd's; Mr. Morcom, of Bellis & Co.; Mr. Soper, of Humphreys and Tennant's; Mr. Hearson, of Cooper's Hill. There are others whom I cannot now remember; and I cannot resist adding, these all originally made their mark by reason of their "high mathematical attainments."

Yours, &c.,
A.E.

Portsmouth, 4th April, 1891.

THE INSTITUTION OF NAVAL ARCHITECTS.

To the Editor of "Industries."

Sir,—Referring to the letter of "M.I.N.A.," dated from Glasgow, on page 327 of your last week's issue, I shall be glad to put on record at least one East Coast member's approval of the suggested alteration of the arrangements of this Institution, so as to permit of at least two meetings being held per annum, one being held in London, the remaining one or more being held alternately in the various shipbuilding and marine engineering centres throughout the country. There must be many members who, like myself, cannot always go to the Institution, and if, therefore, the Institution were occasionally to come to us we should be kept better in sympathy with its movements than is at present the case.

I am also strongly in favour of the view expressed at the late meeting by Lord Ravensworth, that not more than one paper should be read at one sitting, as there would then be an absence of that feeling during the discussion which now exists—viz., that there is such a pressure of business coming on that the less is said in discussion the better. It is generally thought by the members of all such Institutions that, as a rule, as much or more is learnt during a good discussion as by the reading of a paper itself, and, therefore, there is the more reason for giving ample scope to those who wish to continue a discussion.

I presume the idea of permitting written remarks from absent members to be printed in the Proceedings together with the record of the verbal discussions only needs to be mentioned to be adopted, as it would appear to be difficult to find an objection thereto.

For my own part, I have only been able to attend two meetings in six years, and if my case be similar to that of many other North-country members, the force of the suggested alterations will be at once apparent.

Yours, &c.,
An East Coast M.I.N.A.

Hartlepool, 6th April, 1891.

THE BOILER REGISTRATION AND INSPECTION BILL.

To the Editor of "Industries."

Sir,—In a recent article in the *Times* (and reprinted in the *Manchester Guardian*) upon the Bill which has been prepared by the Manchester Steam Users' Association, and introduced into the House of Commons by Sir William Houldsworth and others, several statements are made which are totally incorrect, and, as the subject is an extremely important one to the steam-using community of this kingdom, I trust you will allow me to point them out.

It is stated that "the Boiler Explosions Act of 1882 is not intended for purposes either of prevention or of punishment. It provides only for an inquiry after the mischief has been done." What, then, is to be considered the object of clause 7 of that Act, which reads—"The court may order the costs and expenses of a preliminary inquiry or formal investigation, or any part thereof, including therein the remuneration of persons holding such inquiry or investigation, to be paid by any person summoned before it, or by the Board of Trade; and such order shall on the application of any party entitled to the benefit of the same be enforced by any court of summary jurisdiction as if such costs and expenses were a penalty imposed by such court"?

Since the 29th August, 1889, no less than thirty-one of these formal investigations have been made, wherein fines of various amounts from £10 to £80 have been inflicted, which is sufficient evidence of the punitive character of the Act. Its value in preventing explosions can be sufficiently gathered and is well shown by the figures given in the article, which states that "from the reports of the late Mr. Thomas Gray to the Board of Trade, in five and a half years ending December 31st, 1887, there were 176 persons killed by boiler explosions and 311 injured," or an average of 32 killed and 56 injured per annum. "From the records of the Manchester Steam Users' Association from the beginning of 1871 down to the end of 1890 there were 1,005 persons killed and 1,650 injured," or an average of 53 killed and 87 injured per annum, showing a reduction of 39⅓ per cent. in deaths and 35⅓ per cent. in persons injured owing to the beneficial operation of this Act. It must be noted that during the first seven years of the operation of the Act—viz., until August, 1889, with one exception, preliminary inquiries only were held to the number of 336, and in one solitary instance a formal investigation was made, but without putting the punitive clause in force. Mr. William Summers, M.P. for Huddersfield, then brought these facts before the House, and inquired what were the intentions of the Board of Trade. Sir Michael Hicks-Beach admitted that the Act had not hitherto been properly enforced, and stated that he was "carefully considering whether in the public interest the Act could not be more stringently enforced in future," with the result, as already stated, that since that date no less than thirty-one formal investigations have been held. At the same time Sir Michael Hicks-Beach said, after considering the question, he "did not consider that any further powers were necessary."

I would observe with regard to the comparison attempted to be instituted between the number of boiler explosions occurring on passenger steamers—viz., eleven in a period of ten years upon 1,900 vessels—that no comparison can be fairly instituted without at the same time giving the number of boilers on land, which so far as my opportunities of estimation go would appear to be about 200,000. Further, in regard to these boilers on passenger steamers and also to those under the care of the Manchester Steam Users' Association, it must be observed that they are all internally fired, and of a special class, and in fact the "very pick" of the boilers in the kingdom, which fact would alone render comparison unfair. Further, it is observed, after giving some particulars of two explosions—one at Radcliffe (which occurred nearly nine years ago) and another at Charlesworth, in which another boiler insurance company was interested:—"It is thus clear that the willingness of an insurance company to undertake a risk gives no security whatever for the trustworthiness of the thing insured; the object of the company is not to prevent accidents, but to pay dividends to the shareholders." That this is a grossly false statement can be easily proved, at any rate so far as the operations of the company which I represent are concerned, by a reference to the same documents already referred to—viz., the Board of Trade reports. Since I have been the chief engineer of this company—viz., from the 17th August, 1888—no explosion has occurred where the Board of Trade investigation has imputed any blame either to this company or to any of its officers, and during the last year upon which the present assistant secretary of the Board of Trade reported it will be seen that the Manchester Steam Users' Association have had one explosion out of about 5,000 boilers; while we had only one in over 27,000 boilers; that five boilers under the inspection of Lloyd's surveyors have exploded, and one that was also inspected by both Board of Trade and Lloyd's surveyors. My company employ quite as large a proportionate number of inspectors for the number of boilers they have under their charge as the Manchester Steam Users' Association, and they are equally competent, and are as highly paid. I scarcely think that the Steam Users' Association would for a moment pretend that their inspection is either more frequent, careful, or more reliable than that given by my company, the principal object of which is to prevent accidents, and we think we are fairly successful in so doing.

Whether such one-sided and biassed statements against insurance companies will have the desired effect in reducing their importance I cannot say, and I do not attempt to determine whether any useful purpose can be served by such statements as the following:—"The boiler owner proceeds on a like plan; he knows well that a boiler may be unsafe for a long time before it actually bursts. He dislikes accordingly to be fixed with notice of its faults or to allow them to be exhibited before his workpeople. He works his boiler to death, and he trusts that when the explosion comes, as come it must, it may not prove a specially bad job, or at least that its fatal consequences may be borne by others, not by himself."

There are one or two other sentences which I think are worth the notice of boiler owners in regard to the Bill, such as—"It goes as far as its advocates and promoters think they can go with safety for the present, and without provoking an opposition which might be fatal to the Bill. . . . It it fails on trial it can be strengthened afterwards."

Those boiler owners who think further interference with the working of their plant is undesirable will no doubt look to the

Digitized by Google

matter, and take such steps that the Bill may be thrown out on the second reading, which is to take place on the 21st inst.

Yours, &c.,
J. F. L. Crosland,
Chief Engineer,
The Boiler Insurance and Steam Power Company, Limited.
67, King Street, Manchester, 4th April, 1891.

NOTES ON PATENT LAW.

II.

THE PATENTEES' STATUTORY RIGHTS.

(*Continued from page* 328.)

From the passage in our last article quoted from the Statute of Monopolies, it will be seen that the measure of the rights which a patentee acquires by virtue of the patent grant was not defined, but assumed, and that to ascertain what they were it was necessary to look to the language of the patent itself. So the matter stood until the year 1883, but the Patent Act passed in that year incorporated in its first schedule a form of patent which has thus acquired direct statutory force and authority. What would be the effect of a patent grant expressed in other terms than these may be a nice question for the curious, but it in no way concerns us at the present time, for the Patent Office has no power to grant any patent save in the statutory form, and for all practical purposes, therefore, this is the only monopoly of trading rights which the English law will recognise.

The privilege conferred by this grant is the "full power sole privilege and authority that the said patentee by himself his agents or licensees and no others may at all times hereafter during the term of years herein mentioned make use exercise and vend the said invention within our United Kingdom of Great Britain and Ireland and Isle of Man in such manner as to him or them may seem meet and that the said patentee shall have and enjoy the whole profit and advantage from time to time accruing by reason of the said invention during the term of fourteen years from the date hereunder written of these presents." For the better corroboration of these rights the patent goes on to enjoin "all our subjects whatsoever within our United Kingdom of Great Britain and Ireland and the Isle of Man" to abstain from directly or indirectly making use of or putting in practice the said invention or any part thereof, or in anywise imitating it, or from making any addition to or subtraction from it whereby to pretend themselves the inventors thereof; and, finally, grants to the patentee that the letters patent shall be construed in the most beneficial sense for his benefit.

These clauses contain an admirable summary of patent rights, and will repay careful consideration. For this purpose it should be borne in mind that the "invention" referred to is the invention as defined by the complete specification. It is well known that a specification must accompany every application for a patent grant, and that the patent can only be sealed after the lodging in the Patent Office of a complete specification, which comprises a claim or claims in which the patentee sets forth precisely what he desires to have protected and secured to his exclusive use. Now the invention so defined may be a new product, like the incandescent electric lamp, or a new process, like the recently invented modes of treating alkali waste, or a new combination of old parts, like a patent lock. The language of the patent will cover all these varieties of invention. Thus, if the article be new in itself, no one without the patentee's licence may make, use, or vend it; if it be a new process, the public can only put it in practice subject to the same restriction, and the case of a new combination of old parts is for present purposes on all fours with the case of a completely new article. When properly secured by a suitable claim such rights may be fully effectual to confine to the patentee the entire trade, however valuable and important that may be, in the patented invention. This case is well illustrated at the present time by the well-known monopoly in the manufacture of incandescent electric lamps possessed by the Edison & Swan United Company. This monopoly rests upon a specification in which, in the year 1879, Mr. Edison disclosed the idea of a carbon filament enclosed in an exhausted receiver composed entirely of glass, and having no communication with the atmosphere outside save through the leading-in platinum wires sealed through the substance of the glass. Such a combination contains all the essential features of an incandescent lamp, and although other inventors—Swan in particular—had, before the date of Edison's patent, come exceedingly close to it, they had not actually used or described it. It will easily be believed that at this early date Edison himself did not know how to make anything approximating in serviceableness to the modern lamp. Nobody would nowadays buy, save as a matter of curiosity, a lamp constructed according to the precise directions contained in his specification. But such lamps, though quite unfitted to compete with more modern productions, were distinctly in advance of anything that had been made before, and even the latest lamp containing a filamentous carbon falls within the very comprehensive description that Edison in his specification gave of the lamp which he claimed for his invention. Hence, in spite of numerous improvements in the lamp itself, and in spite of the vast growth of the public demand for lamps of this class, the company which owns this patent has succeeded in keeping competitors out of the field and maintaining a strict monopoly of this most important industry.

It is not against competing manufacturers and vendors only that a patentee can now assert his monopoly. The Patent Act of 1883 has made his patent valid as against the Crown, going in this respect beyond the earlier legislation. But this extension of the patentee's rights is subject to the express limitation that the officers of any department of the service of the Crown may use the invention for the services of the Crown on terms to be before *or after* the use thereof agreed on with the patentee, or in default of agreement to be settled by the Treasury after hearing the parties interested.

Such, in broad outline, are the patentee's rights as laid down by statute; but for their fair appreciation it is necessary to inquire a little more nearly into what precisely is signified by the important words which prohibit the making, using, &c., of the invention by any person other than the patentee or such as have his authority. For in some circumstances the mere possession of a patented article may be in the nature of an infringement of the patent. This was shown some six years ago by a very remarkable judgment obtained by the United Telephone Company. That company complained that another company, the London and Globe Telephone Maintenance Company, had possession of some 800 telephones made in America and imported into the United Kingdom in derogation of their rights. The defendant company pleaded that the instruments in question had never been used by them and that the parts which infringed the plaintiffs' patent had been removed. They contended upon that state of facts that the mere possession of the severed parts of the instruments could not be an infringement, since it clearly was not a making, using, or vending of the plantiffs' invention. And this contention was so far recognised that the judge who tried the case refused to make an order for the delivery up or destruction of the goods, as is usual when infringement has been proved, but, on the other hand, he made an order that the defendants should be restrained from putting the parts together again and from utilising them for their intended purpose during the continuance of the patent, and, what was more important still for the litigants, he made the defendants liable for the costs of the action. This is undoubtedly a case in which the patentee's rights were put very high, but there is no ground whatever for thinking that it was wrongly decided, and it certainly shows that the courts in a proper case will give the most ample protection to a patentee against any invasion, though only threatened, of his patent rights.

On the other hand, it is by no means every possible use of a patented invention which, if unlicensed by the patentee, will amount to an infringement of the patent right. It appears from the terms of the grant that its object is to secure to the grantee that he "shall have and enjoy the whole profit and advantage from time to time accruing by reason of the said invention" during the term of the patent. Accordingly it has been held that a making or using of the invention which does not interfere with this purpose is no infringement. On this ground it has been decided that any person may use it by way of amusement or experiment. This statement needs, however, to be guarded by a reference to the object of the invention, for it cannot be supposed that the making of a patented toy, for example, for the purpose of amusement would be treated as a non-infringement on this principle. But probably it is not worth while, in a discussion such as the present, to refine upon this head. The practical importance of the principle is this—that any person is at liberty to make a patented article for the purpose of experiment with a view to improving upon it without any licence from the patentee. In such a case the object in view is all-important, for any endeavour to evade the patent right under colour of a scientific experiment would be most sternly repressed. On the other hand, the courts will never assist in restricting the facilities of invention and improvement, to cultivate which constitutes indeed the main object of the whole patent law, and hence where mere experiment is in question, made *bonâ fide* for the purpose of improving the invention, no complaint of infringement will be entertained. Whether an experiment made for the scientific purpose of ascertaining the merits of the invention would be equally protected is perhaps not quite so clear, but apparently that would on principle be so, since the only injury which any other maker or user of the invention can possibly do the patentee is that of depriving him of some part of "profit and advantage" arising from it.

There is yet another case of what may be quite intelligibly, though perhaps not quite accurately, called the use of a patented article, of which the patentee is not allowed to complain. That is the case in which the same materials may be applied to two or more totally distinct purposes, and in which one application of them may have been patented, but not the other. The case does not, indeed, often or easily arise, but an instance may be quoted in the case of soft metal packing for pistons, piston rods, and other moving parts of machinery. It was discovered that a perfectly good joint might be made for a pump, for example, by packing the piston with a soft alloy, and a patent was obtained for this invention; subsequently it was discovered that the use of such metal greatly diminished friction in an engine running at high speed, and another patentee obtained protection for soft metal bearings applied to this purpose. In an action brought by the owner of the second patent against the owner of the first, an attempt was made to set up the earlier patent as an anticipation of the later, but it was held that the object, and therefore the use, of the metal under the second patent was quite distinct from that under the first, and although the question of infringement is not the same as that of anticipation, it seems clear that in this case there could be no infringement in the use by the second patentee of what he had himself invented and patented, notwithstanding its close resemblance to what had been patented before.

We are now, perhaps, in a position to sum up in general terms the rights against the public which a patentee obtains under his grant. Without attempting fastidious accuracy, we may define them thus—They comprise the right to enjoy all the profit and advantage which can arise from the exclusive power of making, using, selling, or exercising his invention, and for this purpose to recover by way of damages the amount of any profit or the value of any advantage which may have been derived from this source by other people without his licence, and to restrain by the injunction of a court of law the repetition of any act or the commission of any threatened act which would deprive him of any part of his profit or advantage—in one word, the whole commercial benefit of a monopoly of his invention.

It is evident now that one all-important inquiry is as to how the invention is to be defined. With that topic we shall deal in our next article.

Reviews.

Lockwood's Builder's and Contractor's Price Book. London: Crosby Lockwood & Sons. 1891.

The new issue of Lockwood's Price Book is not in any essential respect different from that of last year. Then it had been considerably enlarged and re-written, bringing it up to date and making it one of the most handy and reliable books upon builders' prices to be had. It must be always be borne in mind, however, in using it, that the prices given are for first-class work only, and in general practice it will be found that these are somewhat in excess of the average value of fair work. Proper attention has been drawn to this in the preface, but another equally important point, which has not been there mentioned, is that where manufacturers' prices are quoted, the catalogue prices are given, and many of these

Digitized by Google

it is well known, are subject to heavy trade discounts. It is very noticeable, especially in the section dealing with sanitation, that appliances which are now discredited are not even mentioned, although this same care has been carried somewhat far in the exclusion also of new forms of apparatus which are undoubtably good. As these have yet to be subjected to the time test, the fault is on the right side. The addition of a few legal notes—which might well be increased in number—and of the Phœnix regulations for electric light installations, are valuable new features in this year's edition of a book which is annually being more largely used.

HAZELL'S ANNUAL FOR 1891. London: HAZELL, WATSON, & VINEY, LIMITED. 1891.

This is the sixth year of issue of this very useful annual, and it is evident that every effort has been made to maintain the position which the book has obtained for accuracy and usefulness. In order to allow room for new material and for the notice of recent events, a good many of the articles in the previous editions have been omitted from this one, but in the index there is a reference to those articles, so that the series of volumes gives a continuous record of events and of the subjects which are being discussed by the public. Among the latter, one stands paramount in importance—the Labour Movement—and this is very fully treated in the pages of the present volume. Changes in foreign politics have been duly noted, while commercial topics have received special attention, and the articles on trade, Stock Exchange movements, insurance, mercantile marine, and the McKinley tariff may be mentioned as examples. Short biographies have always formed a feature in the work, and in the present edition about two hundred of such have been added to the already large number of biographies of the notable men and women of to-day. Lawyers will find a record of the chief legal decisions of the year, and engineers will find details of the several schemes, either completed or in progress, during the last twelve months. Altogether the annual is one of the most useful productions of the present day.

WEBSTER'S INTERNATIONAL DICTIONARY OF THE ENGLISH LANGUAGE. Authorised Edition. London: GEORGE BELL & SONS. 1890.

The thoroughly revised edition of this dictionary, which comprises the issues of 1864, 1879, and 1884, has been the result of ten years' work. We are informed that more than a hundred paid editorial assistants have been engaged in the revision, and more than £60,000 has been spent upon it before the issue of a single copy. The book contains 2,118 pages and nearly 4,000 illustrations, many of which are embodied in the text, whilst others are to be found in the appendix. In addition to the dictionary of words, there are valuable appendices, which comprise a gazetteer of the world, vocabularies of proper names, a dictionary of quotations, and a bibliographical dictionary with 10,000 names. Many terms which have been lately introduced into the language through the development of electricity are found fully and fairly accurately defined, the meaning of the various units being stated with general clearness. Such electrical terms as "hysteresis," "induction," are to be found in this edition, but we notice the absence of the word "henry," which is perhaps too recent an addition to electrical nomenclature to be included. From the very complete character of the work the book is somewhat ponderous, but the illustrations are neat and clear, the letterpress is good, and, viewed as a whole, it is a remarkable example of useful literary labour. We have pleasure in commending it to our readers.

FIRST PRINCIPLES OF ELECTRICAL ENGINEERING. By C. H. W. Biggs. London: BIGGS & CO.

This little work is an elementary book for beginners, and the author has certainly hit upon a "long-felt want" which many people have attempted to fill. As anyone knowing Mr. Biggs' ideas on the subject would expect, the author has carried the notion of circuits almost as far as it will go. He deals with conductive, inductive, and magnetic circuits. We do not agree with the author in this, but, after all, it is really a matter of opinion, and Mr. Biggs is fully entitled to hold his own opinion. There is no doubt that the idea of magnetic resistance helps many students greatly, and Mr. Biggs, therefore, follows out the supposed analogy as thoroughly as possible. It is somewhat out of date to work in what are generally called Kapp lines. This method of calculation never came into general use, and we doubt if Mr. Kapp himself uses it now. There are several slips in the book, which ought to be corrected in the next edition. The book has a copious index, which is a very commendable feature.

REFLECTIONS ON THE MOTIVE POWER OF HEAT, AND ON MACHINES FITTED TO DEVELOP THAT POWER. From the original French of N. L. S. Carnot. Edited by R. H. Thurston, M.A., LL.D., &c. London: MACMILLAN & Co. 1890.

Carnot's "Réflexions sur la Puissance Motrice du Feu," which was published in 1824, and laid the foundation of the modern thermodynamical theory of heat engines was for a long time out of print, and was consequently for many years very scarce. Some years ago it was reprinted by the firm of Gauthier-Villars, Paris, and in one of our earlier volumes we gave a short notice of it. No translation of it in English, however, appeared till last year, when the one above mentioned was issued by the firm of Macmillan & Co. Possibly some critics might say that a translation of such a work was unnecessary, since every one who was likely to read it would be able to do so in the original, but this does not at all follow, for there are many who take an interest in the subject of thermodynamics who have not an easy working knowledge of French. In any case we think that such a work should be accessible to all English readers, and the publishers have done well in meeting this want. They explain that the *raison d'être* for the appearance of the work is not the usual one, and that it is published as matter of limited but most intense scientific interest, and on that score alone. The translation has been edited by Professor Thurston, of Sibley College, Cornell University, and we must say that we could have wished that a little more care had been taken in supervising it, as we have observed several rather serious slips. On the whole, however, the book will fill a want.

Appended to Carnot's work is the celebrated work of Sir William Thomson in which he gave his "Account of Carnot's Theory," and made known to the world the treasure so long concealed and unnoticed, among the scientific literature, already mainly antiquated, of the first quarter of the nineteenth century. Translated from the reprint we have mentioned there is a sketch of the life of Sadi Carnot by his brother M. H. Carnot, while the Appendix contains a number of Carnot's own notes and reflections, many of which are well worthy of study and of being remembered. The book is dedicated to the present President of the French Republic, who is a grandnephew of Carnot.

A NEW NON-CONDUCTING MATERIAL.

WE recently had an opportunity of inspecting a new non-conducting material, which we think will be found exceedingly efficacious as a covering for steam pipes. It is composed of waste cork from the Spanish cork factories, and is compressed into sheets or slabs with some glutinous material. It is then rolled between two sheets of coarsely woven canvas, and its continuity is thus secured. It can when finished be cut into strips or sheets of any desired size. Owing partly to its porous nature, the material possesses very high non-conducting properties, and, being made in several thicknesses, is readily adaptable to all sizes of pipes.

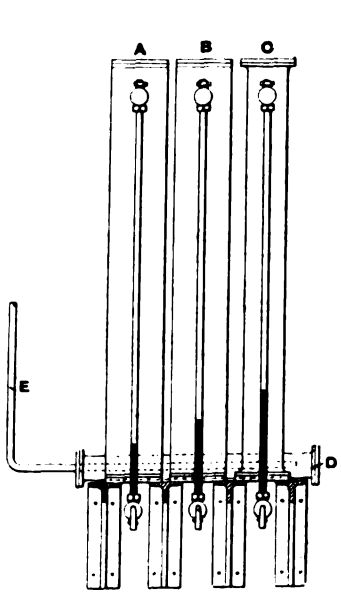

FIG. 1.

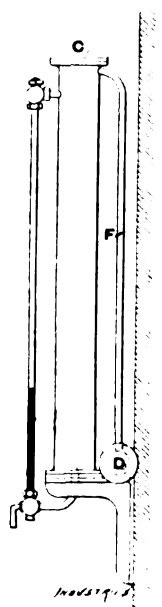

FIG. 2.

For the purpose of exhibiting the non-conducting quality of this material, Mr. Reginald Bolton, of the firm of Messrs. R. Bolton & Co., of 110, Leadenhall Street, London, E.C., who are introducing this covering into this country, has erected in the stores of Messrs. Nicholson & Jennings, electrical engineers, of 132, Horseferry Road, Westminster, an experimental apparatus which we illustrate in Figs. 1 and 2. This consists of three vertical cast-iron pipes, each 5in. diameter, and closed at both ends. One of these pipes marked A is coated with the cork material, the pipe B is covered with an equal thickness of asbestos lagging, and C is left without covering. Each of these radiators is supplied with steam by a pipe F from a receiver D, which receives steam by means of the supply pipe E. The latter extends the whole length of the receiver D, so that the supply of steam to the radiators is unaffected by any exterior circumstances. Separate water gauges are provided for A, B, and C, so that the condensation water can be accurately measured. The results of an experiment made under our supervision are given herewith—

Steam pressure, 30lb. Time of test, 30 minutes.

Weight of steam condensed from cork-covered pipe A	14¼oz.
Weight of steam condensed from asbestos-covered pipe B	23oz.
Weight of steam condensed from uncovered pipe C	35oz.

The material is made in sheets of various thicknesses—that is, from $\frac{3}{16}$in. up to $\frac{3}{4}$in. thick—and in continuous rolls from 2$\frac{3}{4}$in. to 10in. wide.

THE PRINTING, STATIONERY, AND KINDRED TRADES EXHIBITION.

(*Concluded from page* 304.)

MESSRS. BENTLEY & JACKSON, of Bury, showed their "perfecting engines" for refining pulp, which have been described at length in *Industries* (see Vol. VI., page 77), and rag and rope cutting machines. A novelty on their stand was a small indicator, which is intended for attachment to the hopper of the "perfecting engine." This is the invention of Mr. Richardson, and indicates the output of the machine. Messrs. Fielding & Platt, of Gloucester, had on exhibition a 2 h.p. nominal horizontal gas engine, which is too well known to require any special description.

Mr. E. S. Hindley, of 11, Queen Victoria Street, London, E.C., who provided the engines for driving the shafting for the Exhibition, showed a collection of steam engines with and without boilers. The Blackman Ventilating Company, of 63, Fore Street, London, E.C., exhibited their fans, and the Linotype composing machines were also to be seen at work. Messrs. Crossley Brothers exhibited various sizes of their well-known "Otto" gas engines.

Mr. W. C. Horne, of 6, Dowgate Hill, London, E.C., had on view several useful machines. The "Universal" ruling machine, which we illustrate herewith, is a German invention, and is made by the firm of Messrs. Förste & Tromm, Leipzig. Fig. 3, on page 354, shows a general view of this machine, which is strong and compact, and Figs. 1 and 2 represent detail views of the ruling device. The principal feature in the machine is that it rules both sides of the paper at one operation. For this purpose there are two ruling cylinders which are geared together by toothed wheels. The paper when passing through the machine is carried rigidly from the first to the second ruling cylinder, thus ensuring perfect register. On each ruling cylinder there are three ruling spindles (see Fig. 1)

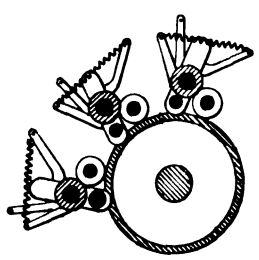

FIG. 1.

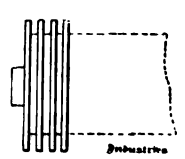

FIG. 2.

and three troughs for ink, which may be of different colours, consequently three colours may be used together. The "striking" gear for "stop-at-head" work is very complete. The end of the ruling cylinder has three grooves (Fig. 2), allowing for the insertion of three different sets of cams, which may be all used together upon one sheet, or kept in position for different sets of headings—as, for instance, one set may be kept in the machine for "foolscap," another for "demy," and one for "post," &c. In the smaller sizes of papers, such as "post" and "foolscap," there is an arrangement, easily adjustable, by means of which two sheets can be ruled by one

Digitized by Google

THE "UNIVERSAL" RULING MACHINE.

EXHIBITED BY MR. W. C. HORNE, 6, DOWGATE STREET, LONDON, E.C.

(*For description see page* 353.)

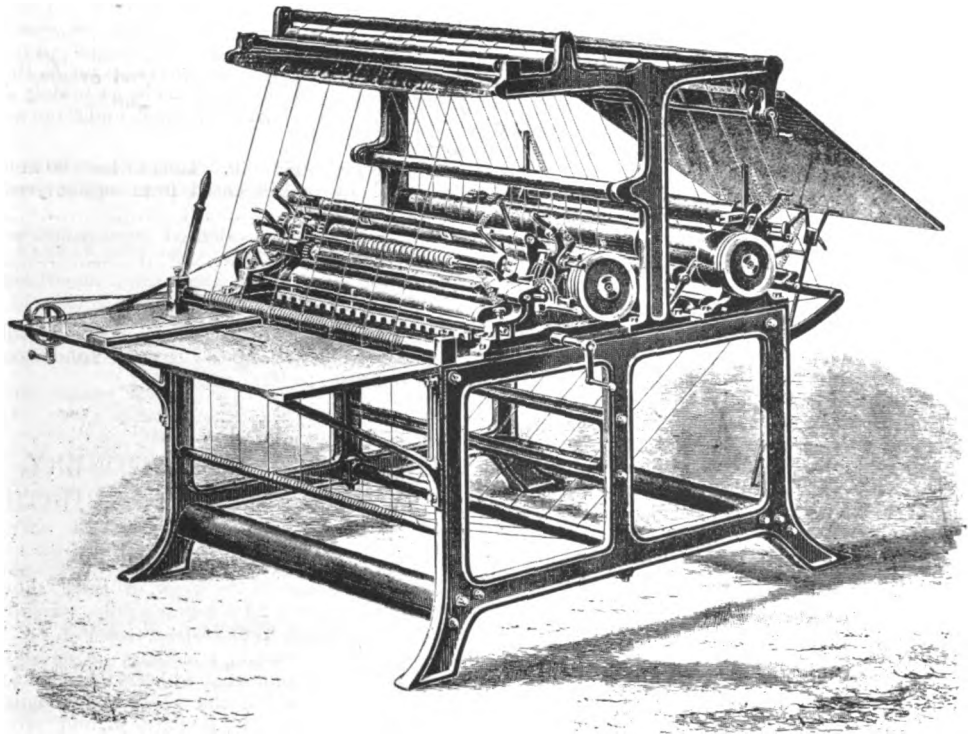

FIG. 3.

revolution of the ruling cylinder. If, when ruling a complicated stop-at-head pattern, it is desirable to stop and do a "run through" job, the only alteration necessary is to loosen one screw, thus avoiding the necessity of removing any wheels or cams. By simply replacing the screw, the stop-at-head job can be again taken up at any moment.

The ruling is done by means of discs of hardened brass, which have many advantages over pens. They will, with care, wear for a very considerable time, and are more quickly placed upon the spindle than pens are as set up in the old wooden frame. It is possible to have four separate jobs on the machine at the same time, any one of which can be worked without disturbing the other. The speed of the machine is entirely dependent upon the feeder. The most complicated patterns can be ruled with a speed equal to ordinary run-through work, and 80 reams per day can be run off complete on both sides. With the discs it is almost impossible to run "blind" lines, and if the pressure be properly regulated at starting and the ink kept well supplied to the troughs there is an absence of broken lines.

ELECTRIC LIGHTING IN HAMPSTEAD.

AT a meeting of the Hampstead Vestry, on the 31st ult., a report was presented by the special committee recently appointed to consider the question as to whether the vestry should undertake the supply of electricity in the parish or permit the Tottenham and Stamford Hill Company to include Hampstead within the area of its operations. Mr. W. H. Preece, F.R.S., had recommended the vestry to undertake the installation of electric lighting, both for street illumination and for the supply of private houses, &c., at an estimated capital outlay of £81,000. With respect to carrying out a portion of the scheme at an outlay of £20,000 or £25,000, or completing the system for the whole parish at once, the committee recommended the latter method, as being likely to be the most agreeable to all residents in the parish.

Mr. Preece estimated that from the private and public lighting an annual revenue would be derived, when the system was in full working order, of £19,500, collected at working charges of £15,800 a year. It is right to explain that in Mr. Preece's estimate of revenue he included £1,400, the increased cost of electric light over gas for public lighting, for which extra outlay about three times the amount of light would be obtained. Even deducting this item there would still remain a profit of £2,300 available towards payment of interest and repayment of capital. The balance of gross profit—viz., £3,700—he showed would be equal to 4·6 per cent. on the capital proposed to be extended. Mr. Preece has calculated that ultimately about 24,000 16 c.p. lamps would be in use, and that the bulk of houses yet to be built would be wired. The cost of wiring and fitting up he put at 25s. per lamp, and the total charge for light 12s. 6d. per lamp, making £12 per annum for twenty lamps, *plus* £25 as the initial cost of fittings, &c. The present cost of gas was, he stated, probably about £10 or £12 a year for the same number of burners, with the addition of charges for plumbing, recolouring of ceilings, &c., so that there would be no material difference between the costs of the two systems. These figures were calculated on the charge for the supply being 6d. per Board of Trade unit.

The report was, after some discussion, received, but the final decision of the vestry was postponed to the 7th prox.

NOTES ON THE DESIGN OF MULTIPOLAR DYNAMOS.*

PREVENTION OF SPARKING IN MACHINES GENERALLY.

FROM the data furnished by a large number of examples, some of which were given in the paper which I submitted for your consideration twelve months ago, an expression for the load which could be safely carried by armatures without causing sparking was obtained; this expression, though admittedly of an arbitrary character, having been proved by my own experience, and that of my colleagues, to have been of some service. In that paper the term "ampere-turns" was employed to denote the product of the number of conductors on the exterior of the armature and the current carried by each, and I am afraid this may have led to some confusion; at least, so it appears from the discussion. In order that there shall be no misunderstanding in the present case, I shall call this product, quite irrespectively of the number of poles, the *volume* of current carried. The volume is therefore the total current flowing parallel to the armature shaft, independently of direction and whatever the number of poles, and it is obtained by multiplying the conductors on the exterior of the armature by the current flowing in each; or, considering the exterior winding as a copper cylinder, it is the total current flowing in its parallel to the axis.

In his paper on "Armature Reactions," read here last year, Mr. Swinburne had worked out the limiting load from a theoretical point of view, and those who were present will remember that to obtain the results given in his paper the author assumed that the brushes were placed almost close to the polar tips. For the moment, however, it will be assumed that the brushes are somewhere near the pole-tips—in their vicinity, let us say—and that the only conductors concerned in producing the cross field are those covered by the pole-pieces. This is sufficiently near the truth for our purpose. Under these circumstances the magnetising force in ampere-turns producing a cross field is, of course, $v\phi/360$, where v is the volume, and ϕ the angle embraced by each pole-piece in degrees. Call l the length of the air gap, measured from the surface of the armature core to the polar surface, and I the induction per square centimetre which would be produced in the gap due to the field magnets alone. When a current flows in the armature the field is weakened at the pole-tips nearer the brushes, and strengthened at those farther from them. Imagine that the armature is loaded so that the forward induction under the nearer pole-tips is just balanced by the cross induction, and we have $v\phi/360 = 2l \times \cdot 8\,\mathrm{I}$, assuming that the components of the cross circuit, other than the air gap, have no resistance. According to this equation, with a value $v = 576\,l\mathrm{I}/\phi$, the forward and cross induction at the pole-tips would be equal, the field would be *nil* at the brushes, and, the machine being unstable, any increase of current would at once cause great sparking.

THE RELATION OF v TO THE DIAMETER OF THE ARMATURE.

But besides taking care that the armature load does not approach the sparking limit, we must provide ample surface for getting rid of the heat generated in the conductors. The first thing to be settled in designing a new machine is what this amount of heat shall be; or, in other words, we must fix the ratio which the energy appearing at the terminals shall bear to the total electrical energy produced. Having settled this, sufficient radiating surface must be allowed to prevent too great a rise in temperature—a point to which due consideration has already been given.

The principal factors which determine the relation of the volume to the diameter of the armature are efficiency and temperature. To carry a given volume we must have, consistent with the waste of power permissible, a certain section of copper; and this copper should be disposed so that a cooling surface is provided sufficient to keep the rise in temperature within the specified limit, while the gap, being of sufficient length to prevent sparking, should have only the dimensions necessary for accommodating the conductors and allowing of proper clearance.

Though the relation lacks definiteness to some extent, I find in the data of a large number of machines indications sufficiently pronounced to justify us in regarding the volume carried by the armatures of two-pole dynamos as proportional to the diameter for all sizes. In designing cylinder machines the value of v may be taken as 400 times the diameter of the armature in centimetres, while for drum armatures the volume is obtained by multiplying the diameter by 600. The cylinder armature has for a given volume a larger diameter, because of the influence of the interior wires. These being heaped inside to one and a half or twice the depth of the exterior winding, also being longer, a larger diameter is required for a given volume, both from efficiency and temperature considerations. Necessarily, the relations here given are not of a hard and fast character, and may be varied considerably. But whatever the proportion adopted, it is absolutely essential that the sparking limit already considered be not too closely approached.

OUTPUT OF DIRECT-CURRENT ARMATURES.

If we call N the total number of lines of force entering the armature from all the poles, however many, and n the number of revolutions per second, the average e.m.f. generated in each conductor is, of course, $\mathrm{N}n\,10^{-8}$. If C be the total current flowing, each conductor will carry, with the sections coupled in the ordinary way, C/p amperes, p being the number of poles. The electrical work due to each conductor is $\mathrm{C}/p \times \mathrm{N}n/10^8$; and the total work, $w\mathrm{C}/p \times \mathrm{N}n/10^8$, where w is the number of conductors, counted all round the exterior of the armature. The quantity $w\mathrm{C}/p$ is what we have called the *volume*, and we get for the total electrical output, in watts, the expression

$$\mathrm{W} = \mathrm{N}nv\,10^{-8},$$

which is quite independent of the manner of coupling up the armature sections. It will be evident, I think, that, with the same relation existing between v and d for two, four, and six poles, the output of an armature of given diameter and length, running at the same speed, is quite independent of the number of poles. It matters not whether N be furnished by two poles only, or by four poles of half the angular width, provided its value remains unaltered.

The volume, then, may be expressed in terms of the diameter. The quantity N may be expressed in terms of the diameter × length of the armature. Taking an induction of 5,000 C.G.S. units per square centimetre in the air gap—a very usual figure—and assuming that the fraction of the armature circumference covered by the pole-pieces = $2{\cdot}25\,d$, we get, calling L the length of the armature in centimetres, 11,250 dL as the total number of lines of force entering the core. Call this, in round numbers, 12,000 dL. Substituting for N and v their values, the output becomes for cylinder armatures

$$\mathrm{W} = {\cdot}048\,d^2Ln$$

and for drum armatures

$$\mathrm{W} = {\cdot}072\,d^2Ln.$$

This applies to all direct-current machines, whether bi-polar or multipolar; though it will be understood, of course, that the induction in the gap may be greater or less than what has been assumed. In that case the coefficients ·048 and ·072 would be altered, without changing, however, the form of the expression.

THE MANUFACTURE OF SOAP.

BY W. LAWRENCE GADD, F.I.C., F.C.S.

(*Continued from page* 332.)

III.

BEFORE commencing a "boil" of soap the pan should be perfectly clean and free from dirt. A little weak lye is allowed to run into it, and the steam turned into the coils. As soon as the lye is set boiling, a portion of the fat

Digitized by Google

or oil to be used is pumped up from the melting-out tanks into the pan, and more weak lye gradually added while the boiling is continued. At first the contents of the pan appear merely as a light, opaque, and frothy emulsion, a small portion of which when taken out of the pan immediately separates into fat and lye; but after a certain time, depending principally on the strength of the lye, the pressure of the steam, and the amount of material boiling, the mixture becomes heavy and semi-transparent, showing that the combination of alkali and fat has taken place. A further quantity of oil or fat may now be added, and, owing to the presence of the soap already formed, this will be more easily saponified, and stronger lye may be used. It sometimes happens that there is some difficulty in getting the fat at once to combine with the lye in a clean pan, in which case the addition of a few bars or scraps of soap materially hastens saponification. In this way the fat and lye are gradually added to the boiling contents of the pan until all the former intended for the charge is pumped in. The boiling is then continued for some time, and stronger caustic lye very gradually added, until there remains, after prolonged boiling, a very slight taste of caustic in the lye, which is separated from a small portion of soap by shaking or stirring, on a shovel, with a handful of common salt.

During this first operation, it is essential that the soap be vigorously beaten or paddled to break up the surface, and so prevent the accumulation of steam in the mass, which would be liable to cause it to "bump" or to froth up and overflow the pan, and also to assist in hastening the saponification. This is sometimes effected by a kind of rotating fan, the blades of which can be adjusted so as

Fig. 3.

to just dip below the surface of the soap, but the common method is to beat it by hand, the spades used being similar to ordinary square light shovels, fitted with long wooden handles, and they are used with a peculiar sculling action, with the handle resting on the pan side. Another form of hand spade is a circular flat iron paddle, as shown in Fig. 3, but the shovel form is perhaps the more useful.

When the saponification of the fat is judged to be complete common salt is thrown into the pan, to throw the soap out of solution, and to separate it from the glycerine, excess of water, and impurities present in the materials used. Before the addition of salt the soap presents the appearance of a uniformly smooth, glossy, and semi-transparent mass, which contains an indefinitely large quantity of water, besides the glycerine formed by the saponification and the impurities of the original fat. On adding salt, however, the appearance and character of the mass undergoes an entire change. The smooth paste becomes opaque and granular, and the ebullition of the boiling soap has a tendency to confine itself to certain points, producing crater-like openings in the curface, and, as a rule, the mass contracts in volume. In this state it is called "grain soap," and is said to be "cut open." This granular form of soap, which contains from 30 per cent. to 40 per cent. of water, and none of the glycerine, separates from the spent lye, and when pressed between the finger and thumb has a dry and flakey feel.

When sufficient salt has been added and dissolved in the lye, the soap should entirely separate from the latter, when a shovelful is withdrawn from the pan, leaving the brown-coloured lye perfectly clear. At this stage the steam is shut off, and the contents of the pan allowed to remain at rest for some hours, during which the grain soap collects in a layer on the surface, and the spent lye and impurities fall to the bottom of the vessel. Excess of salt is to be avoided, both on the ground of economy and also because such an excess causes the mass to froth, and prevents the amalgamation or partial fusion of the grain soap on the surface, which is desirable in order to ensure complete separation; but, on the other hand, an insufficiency of salt will fail to properly cut the soap.

The subsequent quality of the soap depends largely on the first operation being properly performed throughout, and it is without doubt the one requiring the greatest attention from the soapboiler, and demanding the most skill and experience in working it. If the strength of the caustic lye used be too high, there may be difficulty in commencing the saponification of the fat, especially if it be principally composed of tallow, whilst, on the other hand, an insufficiency of caustic, either in quantity or strength of lye, may cause the whole contents of the pan to become a thick, pasty, and heavy mass, which is only remedied with much difficulty and trouble. There is the greatest danger of this when using palm-kernel or cocoanut oil, as these oils are readily saponified, and require a greater quantity of caustic lye than do tallow and most other oils and fats, and on this account it is common, when using these oils in conjunction with other fats, to first saponify the tallow, &c., and to partially or even wholly cut open the soap so formed, with salt, before adding and saponifying the oils. Although the salt may, and probably does, to some extent hinder the saponification of the oil, this method entirely obviates all chance of the mass becoming thick. During the early stages of this operation the steam must be carefully managed, as the light frothy emulsion of fat and lye is liable to boil up suddenly and, if not checked, to overflow the pan.

In addition to the speed at which the lye is admitted to the boiling pan, the quantity of caustic added requires considerable judgment. It is easy to waste a comparatively large amount of alkali by running in more lye than is needed for the complete saponification of the fat, and I have occasionally found samples of spent lye to contain considerable amounts of caustic, in one case as much as 4oz. of caustic soda per gallon of lye, which, on the whole volume run out of the pan, represented a waste of 160lb. weight of real alkali. Many soapboilers avoid waste of caustic by reserving a portion of the oil or fat, and adding this small portion when the main bulk of soap has received a slight excess of alkali; but, by this method, there is the liability of some fat remaining unsaponified, and the best plan is to determine in the laboratory the exact amount of caustic necessary for the complete saponification of the materials, which amount is calculated to volume of lye, the strength of the latter being known, and as the lye tanks are fitted with gauges marked in gallons and parts of a gallon, it can be seen at a glance whether the requisite amount has been run into the pan.

(*To be continued.*)

SOCIETY OF CHEMICAL INDUSTRY.

LONDON SECTION.

On the 6th inst. Professor V. B. Lewes read two papers before this Section. The first paper was entitled, "The Analysis of Illuminating Gases," and in it the author gave a detailed account of the method which he has been led to adopt for the analysis of coal gas and illuminating carburetted gases. This method has already been described by us (see *Industries*, Vol. IX., page 264), and we refer our readers to our previous account for details of the process. The author observed that he had found that besides paraffin, olive oil and alcohol were also good absorbents of the marsh gas hydrocarbons, and that the method which he described had been shown to be trustworthy by examining mixtures of gases of definite composition. He recommended ammoniacal silver nitrate for absorbing sulphuretted hydrogen and acetylene. The precipitate formed by aspirating a known volume of the gas was then treated with dilute hydrochloric acid, when the silver acetylide was decomposed, and the silver chloride formed was then dissolved away by ammonia, reprecipitated by nitric acid, and weighed. The residual silver sulphide was reduced in a current of hydrogen, and weighed as metallic silver. After the removal of the sulphuretted hydrogen, the total sulphur left in the gas was ascertained by passing it over heated platinised pumice, and absorbing the sulphuretted hydrogen formed by ammoniacal silver nitrate as above.

In the discussion which followed Mr. Lacy bore testimony to the obvious merits of the new process, and Mr. Foster described the process which he had adopted to overcome some of the difficulties which the author had referred to, and advocated the use of mercuric chloride as an absorbent for sulphuretted hydrogen. He expressed the hope that he would shortly be in a position to substitute a new absorbent in the place of the unpleasant Nordhausen sulphuric acid.

Professor Lewes' second paper was entitled "The Products of Checked Combustion," in which he described in detail the process he had adopted for investigating the products of combustion of a Bunsen burner as it played on the surface of a copper vessel containing water. These experiments were referred to in the author's recent lectures on gaseous illuminants before the Society of Arts (see *Industries*, Vol. IX., p. 624). The products of combustion were aspirated from the false bottom of the copper vessel, through a series of absorbent vessels arranged as follows:—(1) Tubes containing calcium chloride and caustic potash to remove moisture and carbonic acid; (2) two Volhard tubes, containing ammoniacal silver nitrate to absorb acetylene; (3) a trap tube; (4) a V tube, containing palladised asbestos, followed by calcium chloride and potash bulbs to give the carbonic acid and water formed from the free hydrogen and carbon monoxide; (5) a tube containing platinised asbestos, followed by calcium chloride and potash bulbs to absorb the carbonic acid and water formed from the marsh gas; and, lastly, after passing through a trap tube, the gases were measured by the aspirator. As the quantity of oxygen present in the gases drawn off in this way was insufficient to completely burn the gases, analysed oxygen was introduced by a side tube to the second Volhard tube. The V tube, containing the palladised asbestos, was heated in a bath to 120° C., at which temperature the combustion of the hydrogen and carbon monoxide is rapid, and none of the marsh gas is oxidised. The volume of the gas is obtained by adding the calculated volumes of the gases weighed to those measured in the aspirator, less the known amount of oxygen introduced.

The following table summarises the results obtained with the gases drawn from various heights from above a Bunsen flame:—

Combustion of Coal Gas Flame.

Height from Bunsen in inches	0	0·39	0·79	1·18	1·58	1·99
Composition—						
Hydrogen ...	22·66	14·95	15·49	15·54	14·50	11·95
Methane	33·77	30·20	28·34	21·55	11·92	3·64
Carbon monoxide	7·34	14·07	14·05	14·58	22·24	25·14

Nitrogen.....	29·41	38·66	140·78	184·23	270·45	307·10
Carbonic acid	1·94	2·34	10·11	14·98	23·76	32·34
Water	8·34	11·60	38·85	52·55	72·67	75·61
	111·41	120·09	255·96	311·37	422·59	461·23

A discussion followed the reading of the paper.

MANCHESTER SECTION.

At a meeting of this section, held on the 3rd inst., Dr. Bowman being in the chair, Mr. William Thomson read a paper entitled "Notes on Effluent Water Analyses and on the Methods for Determining the Value of Rival Sewage Processes." The paper was mainly a critical one, and had special reference to the trials recently carried out at Salford by a committee of engineers and chemists. He contended that it was extremely difficult to get really comparable results unless the different processes were tried side by side with the same sewage. The method of mixing a large number of samples taken at different times did not always produce the same strength of sewage, and was, therefore, not a good one. The author laid special stress on the removal of the suspended matters and the organic matters in solution. He recommended the following as a satisfactory method of working:—A tank about five yards square containing an agitator should be filled with the sewage, and a sample of the agitated fluid taken for analysis. If four processes were to be tested the tank should have four taps, and a certain quantity of sewage should be run off for treatment by the different processes ranged alongside. After treatment with the chemicals the sewage should be filtered through canvas bags, the time taken for filtration being noted. The sediment and filtrate were then to be analysed in the usual manner, and the degree of acidity or alkalinity determined with lackmoid or an indicator. The figures thus obtained would, he said, be of great value. He drew attention to the fact that, when raw sewage was allowed to stand, a great deal of the impurities were precipitated, and that frequently the good effects claimed by the promoters of a process were but slightly brought about by the chemicals used. About 3,000 gallons were recommended for each test. Mr. Thomson described the analysis of the effluents, but the methods proposed did not possess any features of novelty except where he drew attention to the mistake of recording the loss on ignition as organic matter. This loss, of course, included combined water, chlorine, &c., and erroneous opinions as to the value of a process were likely to result if the figures were so expressed. The rest of the paper was confined to a criticism of the report recently drawn up by the engineers and chemists of the Salford trials. This report has been printed for private circulation only, and its contents are not therefore generally known. Mr. Thomson contended that the results were not strictly comparable, as no such arrangement as he had just described had been used. He criticised Dr. Burghardt's figures and report, and stated that the report was in direct opposition to the figures given. The processes tried were the "International," "Electric," and Spencer and Barry's. Dr. Burghardt had put down the loss on ignition as "soluble organic matter, &c.," but the author thought that it was mostly "&c." in many of the cases. The figures, therefore, were not trustworthy, nor could he understand how Dr. Burghardt came to report in favour of the Electric process while his figures showed distinctly that the International process was the best.

Digitized by Google

After a short animated discussion, it was agreed to defer further comment till the next meeting, in order to give Dr. Burghardt an opportunity of being present.

Mr. Thomson then described a process for cutting glass tubes and bottles, which, he thought, was not much known, although he claimed no originality for it himself. If two strips of moist blotting paper are wrapped round the glass about ¼in. apart, and the enclosed part heated for a short time with a blowpipe flame, on touching the heated part with water a clean fracture is obtained. Mr. Thomson illustrated this by dividing a Winchester quart into two parts, using only a mouth blowpipe.

A description was then given by Mr. J. C. Cain of a simple method of gravimetric analysis, worked out by Dr. Bailey and himself on the suggestion of Dr. Grossman. The process consisted of calculating the amount of a precipitate, by precipitating in a specific gravity bottle, filling up with water, and weighing. The specific gravity of the precipitate had, of course, to be accurately known. The theory of the method and the corrections to be employed were mathematically demonstrated by Dr. Grossman. It was claimed that the process would prove of special service in cases where the precipitate altered on drying as was the case with sulphides. A series of results obtained by this method when used for the estimation of chlorine as silver chloride, sulphur as barium sulphate, and copper as oxide, agreed remarkably well with those obtained by the ordinary gravimetric methods. The time occupied in a determination is not more than half an hour. No doubt the process will be of service to those who are not frightened by the mathematical corrections involved.

LIVERPOOL SECTION.

At the last meeting of this Section, Mr. A. Norman Tate being in the chair, a paper was read by Dr. G. Schack-Sommer, on the "Introduction of Home Grown Sugar," being a continuation of experiments on the growth of beetroot for the manufacture of sugar in this country. In a previous paper Dr. Schack-Sommer had described the success attained in the growth of beet for this purpose, and his further experiments, which had been conducted both in the neighbourhood of Liverpool and in Ireland, fully confirmed his previous results, and left no doubt in his mind that the industry could be as successfully followed up here as in France and in Germany. The author referred with regret to the apathy shown in the subject by the farmers, who failed to grasp the profitable nature of this new branch of agricultural industry. The author thought the farmers were content to follow on the lines laid down by their fathers, and it seemed as if the raising of a really profitable new crop was to them a matter of perfect indifference. Dr. Schack-Sommer stated that, according to the best authorities abroad, the immediate result of opening a beetroot factory in convenient proximity to the growers would be to increase the value of land by one-third. The choice of suitable seed merited much attention, and the care that had been given to this subject had enabled the agricultural chemist to bring the saccharine strength of beetroot as high as that of the best cane sugar. In France the average quantity of beetroot required to make 1 ton of sugar was in 1881–2 17 tons $3\frac{4}{10}$ cwt., whilst in 1889–90 it had been reduced to 8 tons $11\frac{1}{5}$ cwt.; on the other hand, the average production of sugar per hectare was, on the former occasion, 1 ton $14\frac{1}{6}$ cwt., and on the latter, 3 tons $1\frac{9}{10}$ cwt. The lines on which this remarkable result had been reached were then explained—namely, by a process of very careful selection, and attention to the best methods of growth and of manuring. The process of manufacture of the sugar from the beet was then described, the description being elucidated by diagrams. The root is first sliced into pieces corkscrew-like in form, which are then extracted in a "diffusion battery," consisting of twelve vessels, by lukewarm liquor. The saccharine extract thus obtained is treated three times with lime and carbonic acid and once with lime and sulphuric acid, in order to remove salts and colouring matter, whence it passes through a filter press before being finally concentrated in a vacuum pan. The cost of a beetroot sugar factory capable of treating 30,000 tons was estimated at £58,000, from which a profit of 7¾ per cent. on the invested capital would be realised, and this quite apart from the profit that would accrue to the farmer from the growth of the beet.

An interesting discussion followed, during which the question of the profit likely to be derived from the growth of beet apart from the manufacture of sugar therefrom, was touched upon. This was a point of special interest to the farmer during the tentative stages of the industry, and it did not appear that the utilisation of the soil for this purpose was likely to be a lucrative one compared with other crops. The difficulty at present seemed to be that the farmers were indisposed to foster this new industry until they saw the establishment of beetroot sugar works, whilst the works were not likely to be erected until the growth of beet had been more widely and generally adopted. To meet this deadlock the formation of some sort of syndicate or the taking up of the subject by the Royal Agricultural Society was suggested.

Afterwards a paper was read by Dr. Charles A. Kohn, on the "Application of Electrolysis to Qualitative Analysis." After pointing out that the early attempts to apply electrolysis to chemical analysis were in this direction, Dr. Kohn described a series of experiments he had made on the detection of small quantities of the mineral poisons, antimony, lead, mercury, and copper, taking advantage of the quantitative electrolytic methods of analysis, an account of which he had given to the Society on a previous occasion. The methods were very delicate, clean, and decisive, and likely to be of value in cases of medical and of medico-legal inquiry. These poisons could be detected in the urine directly by means of the electric current, but in the case of the contents of a stomach, &c., the previous destruction of the organic matter by the usual methods was desirable. Very small quantities of silver and of gold could also be detected electrolytically with ease, and the methods had the further advantage of being made approximately quantitative when desirable.

A short discussion followed the reading of the paper.

Notes.

PROJECTED CANAL BETWEEN THE BLACK SEA AND THE SEA OF AZOV.

It is reported that a company has been formed for the construction of a ship canal which will join the Black Sea with the Sea of Azov. The canal will have a length of about 75 miles; breadth, about 73ft.; depth, about 13½ft., which will be increased at the two ends of the canal to about 16ft. Six years are to be allowed for the construction of the canal.

THOMSON-HOUSTON STATIONS IN AMERICA.

According to an electric lighting atlas which the Thomson-Houston Company has issued, the number of their stations in America is astonishingly large. We turned over map after map of the atlas, and found red dots, representing Thomson-Houston stations, in every district. In all the States in which there is much electric lighting the Thomson-Houston system heads the list. The Westinghouse system makes a good second. The atlas in question is a very valuable compilation, as it shows what system is used in every central station in the United States.

THE CORINTH CANAL WORKS.

These works, which had been suspended in 1889 on account of financial difficulties of the Comptoir d'Escompte, were resumed on June 22nd, 1890. When the work was recommenced it was estimated that 3,358,000 cubic metres of earth had to be removed. It is hoped eventually to employ 2,000 men, and raise the monthly removal to 130,000 cubic metres; at present, however, there are less than 1,000 navvies employed, and the monthly result does not come anything near the above-mentioned quantity. Nevertheless March 22, 1893, has been fixed for the opening, yet it is highly improbable that it will be finished by that date. It is generally considered, however, that the present company will be able to carry the work through. Whether the canal, even when completed, will be used for anything but coasting or Adriatic navigation is still to be seen, as, apart from dues, which will of necessity be levied in order to pay interest on capital, the difficulties which attend navigation for larger vessels on either side of the isthmus must not be lost sight of.

NEW RAILWAY STATION FOR ADELAIDE.

The Commissioner of Public Works has laid on the table of the South Australian House of Assembly preliminary sketch plans of a proposed new railway station at Adelaide, estimated to cost about £175,000. The scheme, which is for a building at the back of the present structure, consists of two main divisions; a series of covered roads and platforms, and a suite of offices. The main shed, states *Indian Engineering*, is of the simplest construction, transverse girders 40ft. apart being erected on cast-iron columns and connected by small roof trusses, the whole roof and sides being of galvanised iron. The details of the expenditure involved are as follows:—Permanent-way, £11,200; filling, &c., £11,500; road approaches, footpath, fencing, drain pipes, &c., £3,800; retaining wall, £4,700; main station building, £43,000; parcels and luggage offices, &c., £15,500; customs and resident engineer's offices, &c., £6,700; refrigerating chambers and machinery, £4,000; platform walls and tar-paving, £4,370; main roof, £42,300; verandahs, £3,700; gas, water, and sewerage, £1,700; electric lighting, £4,600; alterations to goods platforms, engine pits, &c., £1,070; signals and interlocking, £6,350; coal gears and sidings to ditto, £9,000; total, £173,540.

TASMANIAN EXHIBITION.

An Exhibition is to opened at Launceston, Tasmania, on the 14th of October next, and it will be carried out under the patronage and with the aid of the Governor and the Government. The scope of the Exhibition embraces every branch of manufacture, but special attention will be given to all classes of mining plant, and the Exhibition thus offers a favourable opportunity to the manufacturers of such machinery in view of the large development of Tasmanian mineral resources now going on. As the Exhibition will take place at a period of the year when Launceston is crowded with visitors, it will afford an excellent opportunity to exhibitors of bringing their goods under the notice of a very large number of colonists. Special arrangements have been made for the carriage of exhibits at greatly reduced rates. It is proposed to supply motive power for machinery in motion free of charge, and medals and certificates will be awarded. Applications for space should be made at the earliest possible date to the honorary secretary of the Tasmanian Exhibition, 5, Victoria Street, Westminster, S.W., from whom all information can be obtained.

EDUCATION IN TEXAS.

The public schools of Texas are rapidly attaining a degree of perfection that will make them compare favourably with those of New England. The permanent free school fund, invested in State and county bonds, is $5,873,174, together with 40,000,000 acres of land controlled by the State, and 17,712 acres, to each county organised and unorganised, controlled by the counties, making a total of 47,288,676 acres, which at $3 per acre would give $141,866,028, and added to the above makes a grand total of $147,739,202. The State University at Austin is one of the best endowed educational institutions in the United States, and is free to students of both sexes. The University Permanent Fund is $523,411 invested in bonds, with an available fund of $21,680, and cash on hand of $10,825, making a total university fund of $555,916, besides which it has 2,221,400 acres of land, most of which was located in early times, and is very valuable, say worth $6 per acre at least, or $13,328,400, making a grand total of 13,884,316 for university purposes. The State Agricultural and Mechanical College, near Bryan, Brazos County, is endowed with $209,000 invested in bonds, and has also a large endowment from the United States Government. Here ninety-four students, half of whom take a mechanical and half an agricultural course, receive free board and tuition.

DECIMAL MEASUREMENTS.

There is quite a movement in favour of the decimal system of measurement just now. When decimal measurements do come in it is to be hoped that they will not be confined to money and length, and such derivatives as volume and weight. There are various other measurements that demand reform—for instance, those of angles. It is absurd to divide the circle into degrees, minutes, and seconds. Even to divide the degrees into decimal parts is only a compromise. What is wanted is to give angles in circular measure, with decimal values. Many calculations involve circular measure. Then thermometers should not be graduated in the present arbitrary manner. They should be graduated according to Sir W. Thomson's scale, and in consonance with the C.G.S. system. The present hydrometer scales should be swept away, and nothing more should be heard of degrees, Twaddel or Beaumé. It would certainly be better to begin by altering weights and measures that are used chiefly by technical and educated men, than to make changes in such customs as selling old and new potatoes by the "sack" and "dozen" respectively in one county and by the "gallon" and local "stone" in another. A county with a local stone may think itself the centre of the universe, and never alter without outside pressure. Again, sizes of books, paper measure, involving as it does various conventionalities, measurements of ropes, sheet lead, gas screw threads, wires, hay and straw, wine, drugs, precious metals, stature of horses, area of fields, and the thousand and one idiotic systems of measurement now in use, will probably take a couple of generations to replace by a system having a rational basis.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

23rd March, 1891.

5136. Wilson & Middleton ... Traverse motion of card-setting machines.
5138. Bagueley, E. E. ..... Steam engine valve gear.
5142. Bowker, Butterworth, & Farrow ..... Strap relieving motion for self-acting mules.
5143. Lewis, G. A. ..... Lock action of magazine rifles.
5158. Vanduzen, B. C. ..... Gas and gasoline engines.
5162. Mills, B. J. B. ..... Devices for transmitting power (*Johnson*).
5163. Lake, H. H. ..... Apparatus for the production of printing surfaces (*Sarigny*).
5164. Parry, W. A. ..... Pug mills.
5177. Grimes, W. ..... Railway signalling apparatus.
5178. Edge, J. ..... Preparing and spinning machines.
5189. Sandino, A. ..... Apparatus for feeding water to steam boilers.

24th March, 1891.

5198. Davies, E. ..... Apparatus for delivering or transferring mail bags from or to trains in motion.
5204. Williams, M. ..... Railway and other signals.
5208. Carter, Carter, Carter, & Carter ..... Valves for steam engines.
5213. Fielding, J. ..... Gas motor valve apparatus
5217. Key, J. T. ..... Apparatus for the manufacture of illuminating gas.
5226. Lanchester, F. W. ..... Gas engines.
5229. Bradbury, J. F. ..... Carding engines.
5234. Jones, T. ..... Machinery for galvanising wrought, cast iron, or steel pipes, bars, and hoops.
5248. Baldinger, W. H. ..... Bottle-filling machine.
5244. Coy, H. E. ..... Screw-cutting machines.
5248. Cottrell, C. B. ..... Printing machines.
5250. Love & Priestman Brothers, Ld. ..... Hydrocarbon and gas engines.
5251. Newton, H. E. ..... Direct-acting engines (*Worthington*).
5253. Lake, H. H. ..... Die rolls for making horseshoe blank bars (*Perkins*).
5254. Lake, H. H. ..... Air compressors (*Hill*).
5256. Lake, H. H. ..... Balanced valves for steam engines (*Canfield*).
5268. Fales, E. ..... Method of and apparatus for generating steam.
5271. Thompson, W. P. ..... Stamping machines for printing (*Alexander*).
5272. Trost, H. ..... Polishing machines.
5274. Standiford & Hyers ... Type-setting machines.
5277. Barrett, T. ..... Punching machines.
5278. Connelly, J. T. ..... Devices for tapping holes. (15th October, 1890.)
5279. Barrett, T. ..... Multiple metal saw apparatus.

25th March, 1891.

5301. Rowbotham & Rowbotham ..... Multiple boring and drilling machine.
5302. Robertshaw & Kaye ... Hard waste breaking machines.
5303. Roots & Seal ..... Gas engines.
5307. Ward & Luck ..... Dredger.
5308. Proctor, J. ..... Mechanical stokers.
5314. Holden, J. ..... Paper-making machines.
5328. Blezard, R. ..... Machines for cutting up rags, &c.
5333. Silvester, F. ..... Mechanism for tipping, screening, and loading coal.
5334. Parmiter, P. J. ..... Machine for breaking up roads.
5344. Reynolds, E. ..... Apparatus for turning heavy forgings.
5349. Seebeck, F. ..... Vertical steam boilers.

26th March, 1891.

5367. Perry, J. ..... Steam engines.
5373. Wheelwright, F. C. ... Loom stopping mechanism.
5374. Holdsworth, W. ..... Spinning and twisting machinery (*Greenwood*).
5395. Norman & Cochrane ... Apparatus for hulling and cleaning grain.
5397. McMullen, J. B. ..... Steel taps and dies.
5399. Middleton, H. ..... Submarine ships.
5415. Bowron, S. ..... Machinery for splitting hides.
5429. Riedler, A. ..... Valves for pumps.

28th March, 1891.

5440. Boulton, I. W. ..... Steam boilers.
5447. Houlden, H. W. ..... Steam engine.
5453. Ashberry & Barnes ... Flexible driving shafts.
5463. Kulage, J. J. ..... Brick-making machines.
5478. Anderson, R. W. ..... Valves.
5481. Eadie & Tannahill ..... Pipe joints and apparatus for making same.
5482. Ivatt, H. A. ..... Railway signalling apparatus.
5488. Burgess, C. T. ..... Chain pumps.
5489. Mackay, M. ..... Apparatus for purifying gas.
5490. Higginson, J., Jun. ..... Gas engines.
5498. Wren & Wren ..... Self-acting balling machine.
5499. Lister, Rodgers, Crosland, & Bannister ... Healds of looms for weaving.

ELECTRICITY.

23rd March, 1891.

5135. Southard, B. D. ..... Armatures for dynamos or motors.
5167. Elmore & Elmore ..... Manufacture of tubes by electrolysis.

24th March, 1891.

5247. Dewey, M. W. ..... Electric heating apparatus.
5252. Graff, E. D. ..... Railway signal apparatus.
5280. Thompson, W. P. ..... Switches (*Willing & Violet*).

25th March, 1891.

5313. Aylesbury, H. ..... Driving electrical machinery.
5318. Boardman & Fairfax ... Arc lamps.
5329. Bristol, L. ..... Portable safety lamps.
5338. Crampton & Essinger ... Carbons for arc lamps.
5341. Poleschko, A. ..... Transformers.
5343. Brockie, J. ..... Arc lamps.

26th March, 1891.

5370. Williams, P. H. ..... Dynamos, motors, and accumulators.
5371. Williams, P. H. ..... Telephones and telegraphs and apparatus therefor.
5412. Parker, T. ..... Means for supplying electricity to electric tramways.

28th March, 1891.

5485. Massin, E. ..... Means for telephonic communication.

CHEMISTRY.

23rd March, 1891.

5169. Duke, Bishop, & Symons Production of aluminium.
5170. Duke, Bishop, & Symons Production of aluminium bronze.
5171. Duke, Bishop, & Symons Metallic alloy.
5184. Johnson, J. Y. ..... Production of monobromo and dibromoparaoxybenzoic acid (*Von Heyden*).

24th March, 1891.

5222. Schneller & Wisse ..... Formation of ozone in presence of air or oxygen and apparatus therefor.
5263. Johnson, J. Y. ..... Production of salicylic acid derivatives containing chlorine and sulphur (*Von Heyden*).

25th March, 1891.

5299. Thwaite, B. H. ..... Method of and apparatus for the production of combustible gases.
5352. Lyte, F. M. ..... Production of alkaline carbonates and chlorine and their derivatives.

MISCELLANEOUS.

23rd March, 1891.

5149. Bengall, J. R. ..... Chamfer plane.
5181. Nunan, E. ..... Flexible hose couplings.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

DRILLING MACHINES.—*J. Brindle, Failsworth, Lancashire, R. L. Reade & J. Taylor, both of Sale, Cheshire.*—The invention embraces a machine adapted for drilling a number of holes simultaneously in the hub or felloe of a wheel. Referring to the accompanying illustrations, Fig. 1 is a vertical section of the improved drilling machine, and Fig. 2 a partial plan showing one of the drills and its adjuncts. Upon a suitable frame A of a circular form are mounted in bearings B the required number of

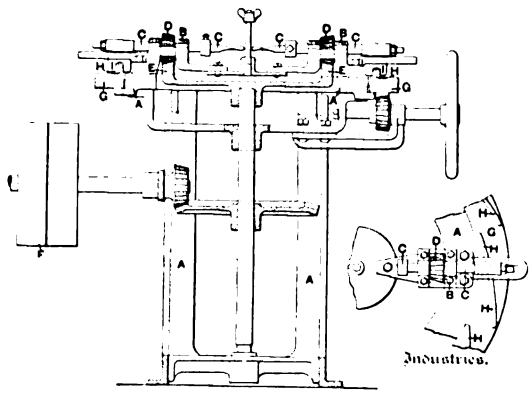

FIG. 1. FIG. 2.

drills C arranged radially at any required angle and at equal distances apart, the bearings B being so arranged that the drills can revolve in them, and are also capable of sliding to and from the centre of the plate or frame. Upon each drill C is mounted on a long key or feather a bevel pinion D between two bearings B. These pinions are all caused to revolve simultaneously by means of a crown wheel E, driven, as shown, from pulleys F. At or near the outer ends of the drills is arranged a circular plate G capable of revolving and provided with inclined curved projections H so formed that when G is revolved by the hand-wheel the projections H acting in the forks I will force the drills all gradually inwards simultaneously. Claims: The construction of improved multiple radial drilling machines substantially as and for the purpose described.—No. 5548. April 12th, 1890. 6*d.*

SELF-ACTING LUBRICATOR.—*G. C. Downing, London.* (*A. Lalance & J. Elsner, both of Paris, France*).—The lubricator embraced by this patent is for the purpose of supplying the cylinders of air compressors with the requisite quantities of petroleum or naphtha, the vacuum produced in the top of the cylinder during the period of exhaustion being utilised for operating said lubricator. A lubricator of this description is shown in the accompanying illustrations, of which Fig. 1 is a sectional elevation and Fig. 2 is a transverse section. A is the oil cup formed in two parts, as shown in Fig. 1; G is an annular reservoir for receiving the oil. C is the lower reservoir, which receives oil from the upper reservoir B by means of the vertical tube B provided with a wick of

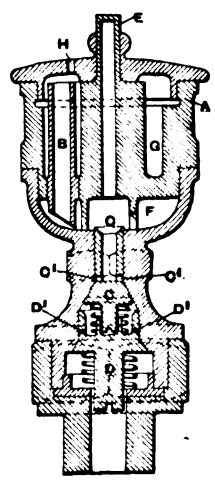

FIG. 1.

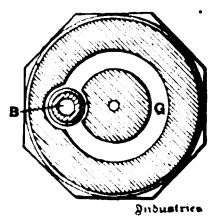

FIG. 2.

cotton or wool. A hole H is formed in the cover to admit the atmosphere to the upper chamber, and holes in the tube F admit the air to the lower chamber. C and D are inverted bronze valves, fitted as shown, and held to their seats by coiled springs. The valves have cylindrical stems, bored out to receive the oil, and small holes C^1 and D^1 to allow the oil to escape when the valves are opened. The action of the apparatus is as follows:—Before the pump is set in motion, oil is poured into the upper chamber and into the tube containing the cotton or wool, also partly filling the lower chamber and shutting off the escape of air therefrom. When the pump is set in motion, the vacuum formed in the cylinder causes the valves to open, and to eject the quantity of oil accumulated in the lower reservoir. The lubrication is effected by drops of oil following each other while the compressor is working, and the quantity is regulated by varying the thickness of the wick in the tube. Claims: (1) The improved construction of apparatus for purposes of lubrication, as described; (2) the general arrangement, construction, and combination of the several parts of an improved self-acting lubricator for air compressors, substantially as described.—No. 4531. March 22nd, 1890. 6*d.*

GAS ENGINE GOVERNORS.—*H. N. Bickerton, Ashton-under-Lyne.*—Pivoted underneath the end of the crank shaft of the engine is a bell-crank lever, one end of which carries an anti-friction roller and is acted upon by means of a cam on the said crank shaft. This motion is transmitted to the engine supply valve by means of the bell-crank lever and a rod pivoted on the other end thereof, the end of which rod is adapted to normally engage a notch in the end of the rod of the supply valve of the engine. Pivoted on the same pivot as the bell-crank lever is a weighted lever, which is caused normally to follow the motion of the former by means of a helical spring, one end of which presses upon a lug on the bell-crank lever, whilst the other end presses upon a nut on a screwed rod pivoted in a short arm or lug on the weighted lever. The other end of the weighted lever normally rests on a projecting lug on the valve-actuating rod on the end of the bell-crank lever. The action is as follows:—When the engine commences to run beyond its normal speed, the weighted lever, not being able to move as quickly as the bell-crank lever is actuated, will overcome the resistance of the helical spring, and will act upon the lug or the valve-actuating rod, so forcing the latter to one side and preventing it engaging the notch in the supply valve spindle. When, however, the engine has regained its normal speed, the bell-crank and weighted levers will be caused to work together by means of the helical spring, and the valve-actuating rod will be forced into its normal position so as to operate the valve spindle by means of a light spring carried by the bell-crank lever and pressing on the opposite side of the lug on said valve-operating rod. The tension of the helical spring is made adjustable, so that the speed of the engine may be regulated. The inventor also describes another form of the above, in which the weighted lever revolves. Two claims are made.—No. 297. January 7th, 1891. 6*d.*

PRINTING MACHINE.—*S. Barnes, Clifton-with-Norwood, near Otley, Yorkshire.*—The object of the inventor is to facilitate the removal of the flyer used in printing machines, for taking the paper from the cylinder when not required and bringing it again into position when required. For this purpose is employed a circular balance disc to which a weight is attached on one side, and the opposite side of the balance is attached to a lever connected to the upright rod carrying the flyer; the balance disc is suspended by a stud having an anti-friction bowl which works within slots provided in the disc. On moving the disc round, it lifts the rod upon which the flyer is fixed out of the way, at the same time it is balanced; on moving it in the opposite direction it brings the flyer into position again and is again balanced. Claims: (1) The use and employment in printing machines of a balance disc with adjustable balance weight, lever, and spring, actuated by the slide carrying the flyer, as and for the purpose described; (2) the use and employment in printing machines of a balanced disc, with adjustable balance weight, weight and lever, actuated by the slide carrying the flyer, as and for the purpose described.—No. 6759. May 2nd, 1890. 6*d.*

STOP VALVES.—*A. Jeffrey & D. Cockburn, both of Shore, Alloa, Clackmannan, N.B.*—The valve box and valve seating are of the usual form. The valve is of the disc pattern, guided by means of a spindle, and is closed or opened by means of a spindle extending through a stuffing box in the cover of the valve box, the outer end of the spindle being screwed and working in a yoke fixed to the cover. The spindle is not fixed to the valve, but enters down through a tubular part connected to the disc of the valve by two side bars. Below the tubular part a collar is fixed on the spindle for lifting the valve. The valve thus has a certain amount of play between its seat and a second seat fixed in the valve casing above it when open. The tubular part on the valve is made with an external groove, in which engage the forked ends of a short lever pivoted on a horizontal spindle in a recess in one side of the valve box. One end of this horizontal spindle, which passes out of the valve box through a suitable stuffing box, carries a weighted lever, which tends to so revolve the spindle as to raise the valve against the upper seating. This action is prevented by a helical spring, one end of which is attached to the weighted lever, whilst the other end is carried by a projection on the valve cover. This upper end can, however, when necessary, be disengaged from said projection by means of a catch pivoted thereon and operated by a cord. The weighted lever is thus allowed to fall, so raising the valve against the upper seat. Claims: (1) Combining the parts of and connected with stop valves for steam and other fluids, as described; (2) in connection with a stop valve capable of being closed on one seat by means of a screw spindle against the current, and of closing against another seat by the action of excess current, arranging a lever to act on the valve, such lever being operated by means of a cord or wire substantially as described.—No. 6703. May 1st, 1890. 8*d.*

LOCOMOTIVE ENGINES.—*G. Simpson, London.*—The inventor's object is to prevent the escape of sparks of fire from the funnels of locomotive engines. Within the ordinary funnel is fixed an inner tube or funnel equi-distant from the outer funnel and resting upon proper grids or supports. This inner tube is preferably about 6in. less in diameter than the outer funnel and is held upright by suitable stays and does not reach the top of the outer funnel, but carries upon a transverse grill a vertical rod which supports a curved and perforated iron plate extending slightly over but not touching the top of the inner funnel, and acting as a hood. Connected to the bottom of the outer funnel is a tank of water. The exhaust steam pipe from the engine is taken into the centre of the inner funnel. The sparks from the boiler fire are thrown against the perforated hood and rebound into the tank of water below. Two claims are made embracing the arrangement as described, with modifications.—No. 7798. May 19th, 1890. 6*d.*

SLIDE VALVES.—*J. T. Jameson, Sunderland.*—The object of the inventor is to diminish the pressure and friction on slide valves exposed to high pressure steam. For this purpose the slide is constructed of the ordinary hollow form, but with a bar arranged in the centre of the hollow part, so as to form a port at each end of the bar, said ports being of a similar size to the central steam admission port on the cylinder face, and serving to admit fresh steam to the interior of the slide valve, whence it is distributed to a port at each end of the cylinder face and leading to each end of the cylinder. The exhaust is released directly past the ends of the valve into the valve box. In order to counteract the tendency of the valve to lift when the steam is first admitted to the interior thereof, a plate is provided which, by means of a bent spring, is made to bear on the back of the slide valve. Claims: (1) A slide valve, of D form, provided with a central bar in the hollow, and ports at each end of said bar, and working in a chamber which receives the exhaust fluid, in combination with a central steam admission port on the cylinder face, as and for the purpose set forth; (2) the application of the slide valves to triple and quadruple cylinder expansion engines; (3) the slide valve as described.—No. 3766. March 10th, 1890. 6*d.*

CARDING ENGINE FLATS.—*W. H. Richardson, Oldham, Lancashire.*—The invention consists of an arrangement for facilitating the adjustment of the travelling flats to the cylinders of revolving flat carding engines. Referring to the accompanying illustrations, of which Fig. 1 is a side elevation and Fig. 2 a cross section, the

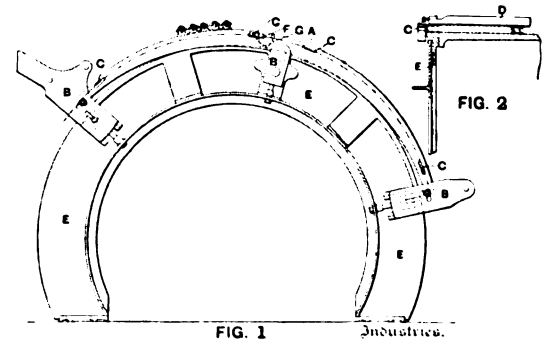

FIG. 2

FIG. 1

flexible bend A is supported by means of the ordinary brackets B, and has formed in it four slots C. These slots are made in such a position that they come exactly opposite the points of the teeth or wire of the flats D on A, and the points of the teeth or wire of the cylinder E. It will thus be seen that, by inserting a strip of metal in said slots, the position of the flats can be adjusted. Suitable plugs or covers F attached to the machine by means of a chain G are provided for closing the slots C when the engine is in operation. Claims: (1) In a revolving flat carding engine, flexible bends or other appliances provided with slits or openings by means of which the position of the points of the teeth or wire upon the flats in relation to the teeth or wire of the cylinder may be ascertained or tested as described; (2) for use in conjunction with slits or openings formed in the flexible bends or other appliances of a revolving flat carding engine, plugs such as F employed to prevent dust, "fly," or cotton from being blown out through the slits or openings.—No. 6684. May 1st, 1890. 8*d.*

GAS PRODUCER.—*S. Griffin, Bath, Somerset.*—The present invention embraces an apparatus for producing combustible gas for gas engines by the admixture of any suitable liquid hydrocarbon in a finely divided state with ordinary atmospheric air. Fig. 1 in the annexed illustrations is a vertical section of an apparatus for the above purpose, Fig. 2 being a horizontal section of the carburetter. Fixed to a suitable base are the two cylindrical vessels A B, one inside the other. The smaller vessel B contains the liquid hydrocarbon supplied through pipe B^1, and is connected by a passage C governed by a float valve, float chamber D, and passage E, with the carburetter F, the upper end of which is connected by pipe G with the interior of a bell or gas container H arranged to slide over B but contained in A. The interior of F is also connected with the air supply pipe I by means of valve J, cover J^1, and finely perforated radial pipes J^2. K is the air superheater, L the gas delivery pipe, and M an air relief pipe

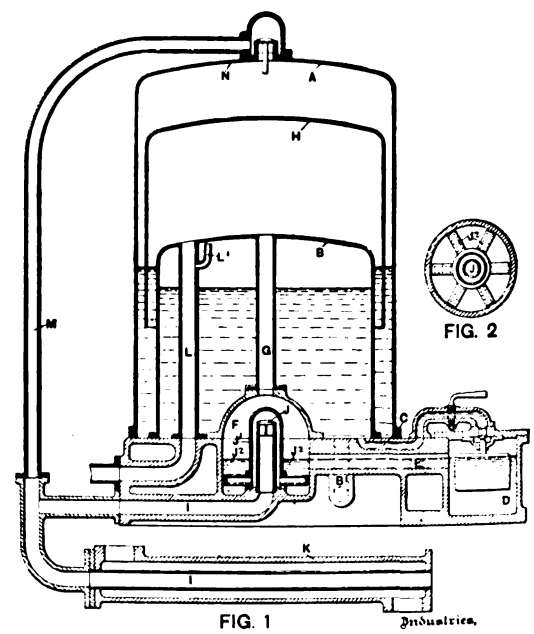

FIG. 2

FIG. 1

connecting the interior of A with I. L^1 is an equilibrium pipe, and N equilibrium holes. The action is as follows:—As the air passes through the perforations in the pipes J^2 and through the liquid hydrocarbon in F, the former absorbs the latter, and the mixture so formed passes into H and is ready for use. In seven claims the inventor embraces the general construction of an apparatus as described and for the purpose set forth.—No. 6217. April 23rd, 1890. 8*d.*

GAS ENGINES.—*A. A. Domington, Longsight, near Manchester, & H. Coates, Manchester.*—The improvements embraced by this invention consist in having two cylinders, one placed above the other, the top cylinder being in a horizontal position and the lower cylinder at an angle, or the lower cylinder may be placed

Digitized by Google

horizontally and the top one at an angle, or both cylinders may be placed at an angle, the connecting rods of each engine being coupled to the same crank-shaft. This arrangement may be adapted in using several cylinders in the positions and angles as described. Claims: The position and angles of the cylinders as mentioned.—No. 6910. May 5th, 1890. 4*d.*

STEAM ENGINE REVERSING GEAR.—*W. Thompson, Clouds Hill, St. George, near Bristol.*—Fig. 1 in the annexed illustrations is a side elevation partly in section, and Fig. 2 a part sectional plan of a reversing arrangement embraced by this invention. Fixed to one side of the eccentric A is a bevel wheel B loose on the driving shaft C and gearing with a second bevel wheel D loosely centred on the reversing lever E which is screwed into a socket F loosely encircling the driving shaft C. A third bevel wheel G

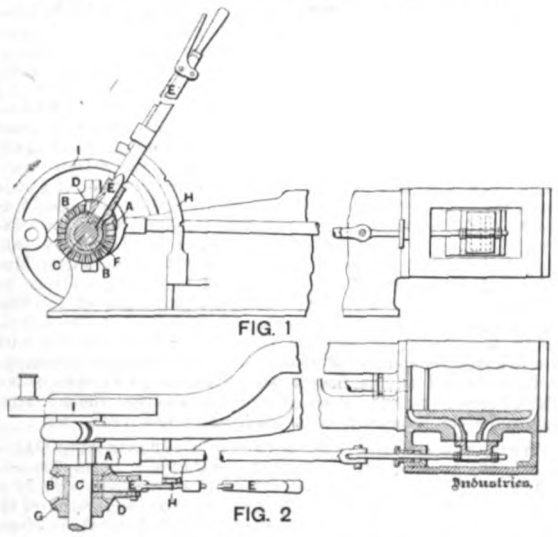

FIG. 1

FIG. 2

fixed on the shaft C also gears with the wheel D. When the reversing lever E, which works in a notched quadrant H, is moved about the driving shaft C, whether the engine be stationary or in motion, the eccentric A is moved round on the shaft through the train of bevel gearing B D C, and the direction of motion of the crank I determined accordingly. The inventor also describes a modification of the above, and both of such arrangements are embraced in three claims.—No. 19305. November 27th, 1890. 8*d.*

SECTIONAL WARPING AND BEAMING MACHINES.—*J. H. Stott, Rochdale, Lancashire.*—A machine such as is embraced by the invention is shown in the annexed illustrations, of which Fig. 1 is a side elevation and Fig. 2 an end view. In suitable framework A is carried the horizontal driving shaft B, on which is fixed, by means of a feather, so that it revolves with but can be moved longitudinally along said shaft, a sleeve, carrying two bevel wheels C, either of which may be thrown into gear with bevel gear D^1 on a shaft D by means of a lever E The shaft D carries a frictional disc F, which can be moved into or out of gear with a frictional disc G on the shaft H carrying the "section block" I by revolving a hand-wheel J. In the upper part of the framework are journaled three rollers K, one of which receives motion by means of suitable gearing from B. The bearing of the upper roller is adapted to slide vertically in slots in the framework, and the roller itself may be pressed down upon the other two by means of weights L carried by a frame supported on the said spindle. The yarns as they pass from the creel first pass through a "vee reed" M, then under the first of the lower two of the three rollers, over the upper one, and again under the second of the lower two. From thence it passes around a roller N to the "section" roller. The roller N, which

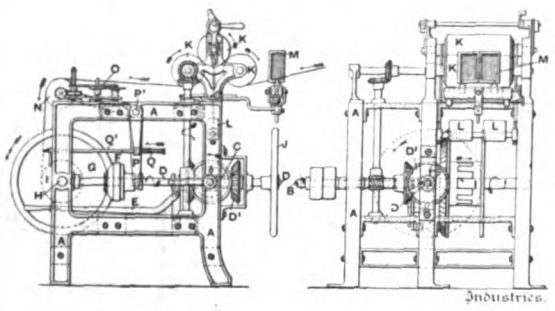

FIG. 1. FIG. 2.

is in gear with a measuring device O, is journaled in the end of the bell-crank lever P pivoted at P^1, the other arm of which carries a stud which projects into a groove in F. A helical spring Q carried on a rod Q^1 tends, by pressing against one arm of P, to hold said lever in the position shown, but should the pressure of the yarn upon N become sufficient to overcome the resistance of said spring the lever P will be moved sufficiently to throw F out of gear with G. In three claims the inventor embraces the general construction of a sectional warping and beaming machine as described.—No. 2850. February 22nd, 1890. 8*d.*

MACHINERY FOR THE MANUFACTURE OF PROJECTILES.—*T. Davage & S. Taylor, both of Sheffield.*—The invention relates to a method of and apparatus for rolling hollow or solid elongated projectiles and to improvements in forging same. In carrying out the first part of the invention a pair of disc rollers fixed upon the end of two horizontal shafts, and driven in the opposite direction, are used. The opposite faces of these discs have formed on them concentric circular projections, which projections are so bevelled off at their peripheries that the two edges together correspond to the radius of the point of the required projectile. The point of a bar of metal may thus be pointed by placing it between said rollers. This partly formed projectile has then a hole drilled or otherwise formed in its base. It is then placed on a suitable mandrel and by hydraulic power advanced between the faces of two other finishing rollers of a similar construction to the last named, the mandrel being capable of rotating with the shell. According to the second part of the invention, a bar of steel is either pressed or forged in suitable dies into a blunt conical form, the base of which is larger than that of the required shell. A hole is then formed in the base and a mandrel inserted. The whole is then placed between a pair of dies approximating to the required shape of the shell, and which also have recesses to receive a collar upon the mandrel. The operation of the dies, which are fixed in a steam hammer, reduces the forging in diameter and elongates it upon the mandrel. Four claims are made.—No. 6963. May 6th, 1890. 8*d.*

COTTON-OPENING MACHINES.—*J. Dunn, J. W. Pateson, W. Riley, & J. Wilding, all of Preston, Lancashire.*—The invention has for its object to increase the means of cleaning the cotton during its passage through the suction tube or trunk of a cotton-opening machine or "porcupine." To effect this the interior of the upper arched part of the tube, and in some cases its two perpendicular sides, are provided with short projecting teeth or pins, against which the flying cotton, as it is drawn through the tube, strikes, so more effectually liberating the dust contained in it. The flat metal bars forming the grate or grid below are arranged longitudinally or in the same direction as the length of the tube. Claims: The application to the suction tubes or trunks of cotton-opening machines of internal projecting teeth, pins, fingers, or other equivalent obstructing media, substantially as and for the purpose set forth.—No. 6991. May 6th, 1890. 6*d.*

SALT WATER EVAPORATOR.—*J. Kerr, Waterloo, near Liverpool.*—The evaporator embraced by the present invention is to supply extra feed for marine boilers which are used in conjunction with surface condensers. Such an apparatus is shown in vertical section at Fig. 1 in the accompanying illustrations, Fig. 2 being a plan of the heating coil. A cylindrical vessel A is bolted on to the top of the main condenser, and has secured to its upper end and projecting into it the second or inner vessel B. Within this

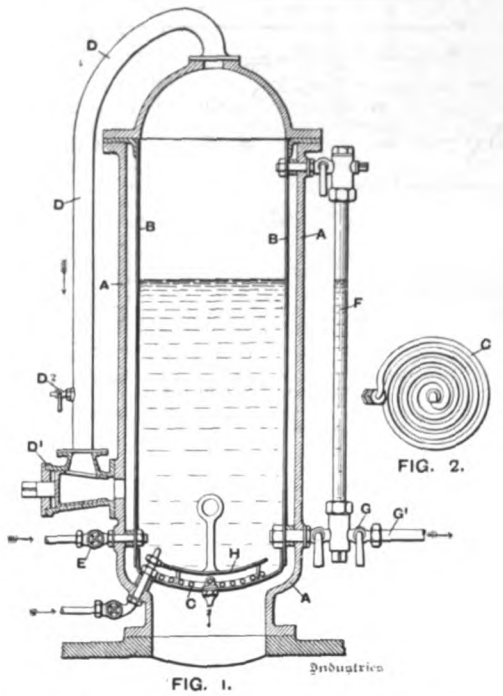

FIG. 1.

FIG. 2.

inner vessel, and resting on the bottom thereof, is a flat spiral coil C (Figs. 1 and 2) of thin metal tubing. One end of this coil is passed through the inner and outer vessel, and is connected to the boiler. The inner end passes through the inner vessel and opens, in the form of a contracted nozzle, into the condenser. The inner vessel contains the water to be evaporated, the vapour from which escapes, through a pipe D, from the top thereof to the main condenser, the passage of the vapour through said pipes being governed by a cock D^1. The water to be evaporated is supplied through pipe E. As the water in B becomes concentrated, it is drained out by cutting off communication between A and B, opening a small cock D^2 in D, and allowing the water to escape through the lower cock of the gauge glass F, cock G, and pipe G^1. A deposit-collecting pan H is also placed in the lower part of B to prevent deposition of scale upon the bottom of the inner vessel. Six claims are made.—No. 5891. April 18th, 1890. 8*d.*

BENCH VICES.—*D. Bateman & R. Sellers, both of Bradford, Yorkshire.*—The invention embraces a simple method of disconnecting and connecting the movable jaw with the screw of instantaneous grip vices. For this purpose a half-nut is rigidly attached to the fixed jaw, and is cut with a "buttress" screw thread. The said nut is fixed below the screw carried in the movable jaw, the thread on which is of a similar type to that on the half-nut. The screw is so mounted and arranged that it may be lifted out of engagement with the nut, and allow the movable jaw to be rapidly adjusted. The face on the movable jaw, against which the shoulder on the screw bears, is inclined towards the nut, and thus tends to press the screw against the nut. A spiral spring is placed on the rear end of the screw to prevent "back lash." To regulate the angle of the jaws and adapt them to uniformly grip a tapered object, the guide in the fixed jaw is formed wider in front, so that the slide of the movable jaw is free to move to either side. Claims: (1) In a vice, mounting or arranging the screw so that it is capable of being disengaged by hand from the nut, as described; (2) the construction and arrangement adapting the angle of the sliding jaw to be adjusted, as described.—No. 4932. March 29th, 1890. 6*d.*

DOUBLE-ACTING STEAM ENGINES.—*C. A. Tower, Cleveland, Ohio State, U.S.A.*—Referring to the annexed illustrations, Fig. 1 is a side sectional elevation, Fig. 2 a horizontal section, and Fig. 3 an end sectional elevation of a machine constructed on the principle of this invention. Journaled centrally in a suitable casing A is the main crank-shaft B, the crank of which is embraced by the piston C of the vertical cylinder D, which latter is adapted to slide horizontally in the casing between the ends of the two horizontal cylinders E, the pistons F of which are connected by screws F^1 to the cylinder D (Fig. 1). At each side of

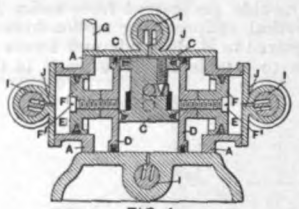

FIG. 1

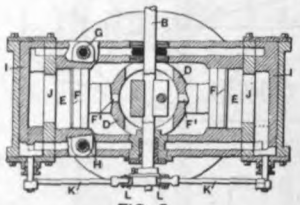

FIG. 2

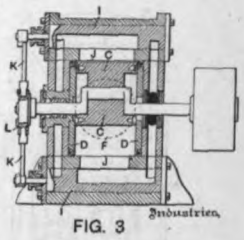

FIG. 3

A are provided a set of channels connected respectively with the supply and exhaust pipes G H, the opposite ends of each set of channels being connected with the interior of the casing of four valves I, in each of which are formed two ports extending respectively sufficiently far to the opposite ends to form communication between the exhaust or supply channels and that end of the cylinder above which it is placed through ports J. The valves I are all connected by rods K to a ring L embracing an eccentric in the shaft B, and are so operated as to cause the pistons of the three cylinders to work together and give B a continuous rotary motion. Nine claims are made, embracing the general features of an engine as described.—No. 225. January 6th, 1891. 8*d.*

SHIPS' STEERING GEAR.—*R. Roger, Egglescliffe, Yarm, Yorkshire.*—This invention has for its object the improvement of the method of safely controlling the movement of the uncoupled ends of the connecting rods of ships' steering gears of the "right and left hand screw" type when such gears are disconnected, to allow of the use of other means of steering. For this purpose the nuts (which travel on the right and left hand screwed spindle and actuate the rudder through the connecting rods and cross-head) are so formed that, when the rods are disconnected from the nuts by the withdrawal of the joint pins, the rods are only moved within guides connected to or forming part of the nuts, and in the form of tubes of a size sufficiently large to allow the ends of the rods moving inside them. Claims: The application to "right and left hand" screw steering gear of nuts having guides attached to them or forming part of them, which guides control the motion of the disconnected rod ends, as described.—No. 14860. September 20th, 1890. 6*d.*

BOLT CUTTER.—*H. J. Haddan, London.* (*J. Helwig, Dubuque, Iowa State, U.S.A.*)—The cutter forming the object of this invention is adapted for heavy cutting, such as cutting stay bolts of locomotive boilers, &c. A front and side elevation of such a cutter is shown respectively in Figs. 1 and 2 of the annexed illustrations. The two levers A, carrying in their upper ends the cutting knives and the actuating lever B, are pivoted at C C^1 to

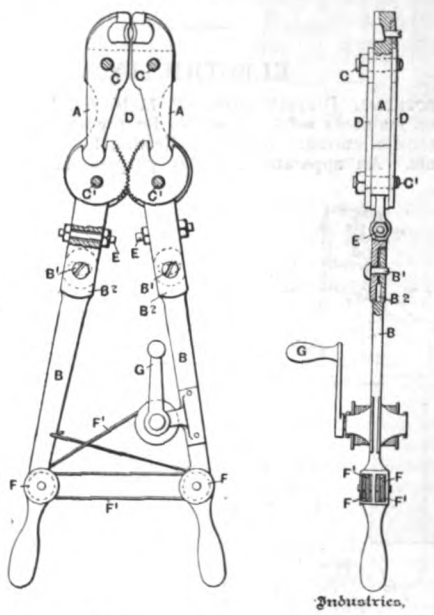

FIG. 1. FIG. 2.

plates D. The lower ends of A are provided with knuckles, which enter recesses in the upper ends of B, the inner faces of the upper ends of which are formed with teeth as shown. Suitable stops E are provided for preventing B coming too close together, and pulleys F are held in the lower part of said levers, around which passes the actuating cord F^1 operated from handle G as shown. The levers B are formed in two parts fixed together by means of screws B^1 and engaging teeth B^2. Four claims are made.—No. 892. January 17th, 1891. 6*d.*

Digitized by Google

BRICK MACHINES.—*J. S. Pullan, W. H. Mann, & J. Gill, all of Leeds, Yorkshire.*—A machine such as embraced by this invention is shown in the annexed illustrations, of which Fig. 1 is a side elevation and Fig. 2 an end elevation, Fig. 3 being an enlarged detail thereof. The clay, in a plastic condition, is fed into the hopper A, and by means of a screw B, operated from B^1, is forced downward and into one of the two openings in the slide C (Fig. 3). This slide receives a reciprocating motion, so as to bring the two openings therein alternately under the mouth of the hopper by means of a rod D operated by a crank in the spindle of the gear wheel E, which wheel is geared to the driving shaft F. As the moulds are moved from under A a pusher, which receives a vertical reciprocating motion from the shaft G (Fig. 2), which is geared to E, descends and forces the brick out of the mould on to a table H. The brick is then

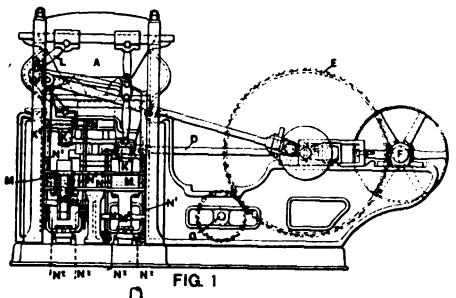

FIG. 1

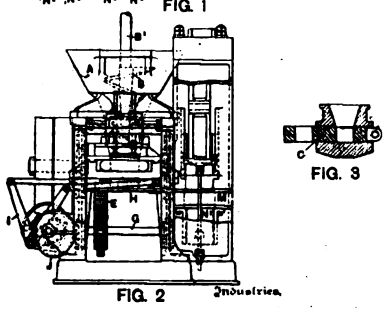

FIG. 2

FIG. 3

moved on to the surface of a plunger in one of two pressing moulds by one of the levers I, operated by means of a cam J on a horizontal shaft geared by bevel gearing with G. The rams K of these two pressing moulds slide in guides K^1, and are operated by means of two pairs of toggles connected together by a link (Fig. 1) and a rod L from the shaft of E. The moulds M have in them plungers M^1, which are connected to their respective rams by cross-bars N and rods N^1, furnished with elastic cushioned stops N^2. It will thus be seen that as the rams ascend the mould plungers will also ascend, so forcing the pressed brick out of the mould. Claims: (1) An improved duplex pressing machine for finish pressing bricks (in which the pressure is imparted by toggle movement) connecting two systems of toggles by a link, and actuating the same by one connecting rod from a rotating crank, the whole constructed, arranged, and operating as described; (2) the combination of a brick-making machine of the semi-plastic or other type, with the improved pressing machinery as described; (3) an improved pressing machine of the single type, having only one mould and plunger of the same kind as in the duplex machine referred to in Claim 1, in which one system of toggles is caused to pass beyond the dead point on both sides thereof, and pressing a brick at each passage of such dead point by the said toggles, thus pressing in and discharging from one mould two bricks at each rotation of the actuating crank.—No. 4368. March 20th, 1890. 8*d.*

ELECTRICITY.

ELECTRICAL DISTRIBUTION.—*H. E. Walter, London.*—The invention embraces safety apparatus for preventing danger from high-tension currents and for indicating faults in low-tension currents. An apparatus for this purpose is shown in side

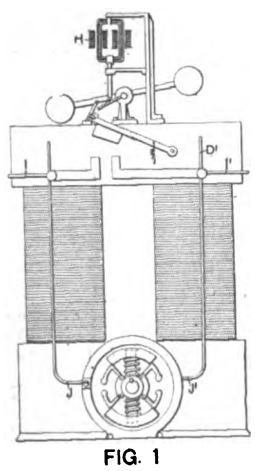

FIG. 1

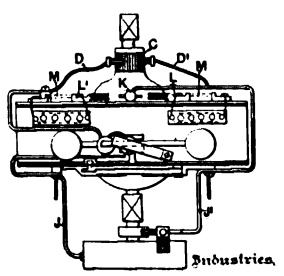

FIG. 2

elevation and plan respectively in Figs. 1 and 2, and a diagram of the connections thereof is shown in Fig. 3. Referring mainly to the diagram, A represents the generators supplying a three-wire system, of which B B^1 and B^2 are the main conductors. C is the armature of a switching electric motor placed at the central station, one pole of which is connected by a heavy conductor D with the neutral wire B^2 and the other pole by a heavy conductor D^1 with the earth. The coils of the field magnet E are connected by wires F F^1 from one terminal to the negative main conductor B^1, the other field terminal being joined to the wire D, so that the field is connected between the negative and neutral wires and is constantly charged. G represents an ampere meter in the ground connection, and H is a magnet controlling an alternating current switch adapted to close the circuit I I^1. A centrifugal switch of the motor armature is arranged to close the circuit J J^1 around such armature. K is a pivoted switch lever connected by wire with the grounded terminal of the motor armature and arranged to be placed in contact with one or the other of the plates L L^1 normally connected through incandescent electric lamps, the plate L^1 being connected with the wire extending to the negative main and the plate L to the wire extending to the positive main. These plates are also arranged to be connected by fusible safety catches M and wires M^1 M^2. N is the generator supplying a high-tension continuous current system, the main conductors of which are O O^1. The other connections are made substantially as shown in the diagram. The operation is as follows:—Suppose a ground connection to occur on the negative wire B^1 as indicated at P a ground circuit will be formed by means of wires D D^1 through the armature C, and the motor will be caused to run. If the ground connection was on the positive side the motor would run in the opposite direction. It will thus be seen that a ground exists, and on which side it exists, and such ground cannot result in injury to the system since the motor forms a translating device preventing an excessive flow of current through the earth. As a ground on the neutral wire does not affect the motor, the switch K may be used for testing for grounds thereon, the negative conductors being connected to ground through the resistance lamps, so that if there is no ground the motor will then run at its normal speed, but if a ground is made it will move very slowly. If the negative wire comes in contact with a wire of high-tension system as shown at P^1, and said high-tension system is grounded at P^2, by the above-described arrangements a low resistance path to ground for the high volt current is already provided, so that difference of potential does not occur. When a

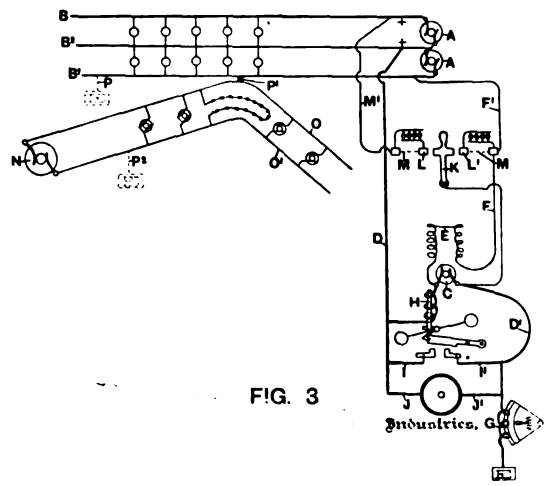

FIG. 3

high volt connection is made the motor C attains a high speed, so that the centrifugal governor is operated and closes the circuit J J^1, so stopping the motor. The inventor also describes an arrangement in connection with continuous current transformer systems. Five claims are made.—No. 2876. February 22nd, 1890. 8*d.*

FILAMENTS FOR INCANDESCENT LAMPS.—*H. H. Lake, London.* (*V. M. Hobby, New York, U.S.A.*)—The composition consists of the following ingredients, combined in the proportions stated:—Carbon, 1oz.; sugar, 1oz.; liquid mucilage, 1oz.; and liquid india ink, 1oz. The ingredients, after being thoroughly mixed to form a paste, are dried and cut with a knife to form a filament, then carbonised in the following manner:—The filament is placed together with a lump of the above paste in a graphite pot just large enough to contain them and a frame of wood, upon which the filament is wound. A graphite cover is then placed upon the pot and made air-tight by sealing with fireclay. Said pot is then put in a large graphite pot, having a space of about 2in. all round, which space is then filled with powdered graphite, lampblack, or powdered charcoal, and a cover put on and sealed. The whole is then raised to a white heat in an oven, and allowed to gradually cool. The filament is then cut to proper lengths, and is ready for use. Four claims are made.—No. 13791. September 2nd, 1890. 6*d.*

ARC LAMPS.—*R. Belfield, London.*—The lower carbon is stationary, but the upper carbon is attached to a rod having a rack gearing with a pinion on the axis of an escapement wheel which is engaged by an anchor on the axis of the brake wheel. When the brake wheel is free, the weight of the carbon and its holder causes it to slowly descend, turning the escapement wheel, and causing the anchor to vibrate the escapement anchor and brake wheel are mounted in bearings in a frame suspended from one arm of a nearly balanced lever near its fulcrum. The ends of this lever have suspended from them iron cores free to move inside two solenoids. The coil of one of these solenoids is of fine wire, and in a shunt to the lamp circuit; the coil of the second solenoid is of large wire, and in the lamp circuit. Thus movement of the gearing for releasing or holding the brake wheel is completely governed by the current passing through said solenoids. Claims: (1) In an arc lamp, in combination with a rack rod carrying the upper carbon, a pinion and escapement wheel, and an anchor and brake wheel or segment, all suspended from a lever carrying a core acted upon by a solenoid, so that when the resistance of the arc increases the brake wheel descends from a brake, thus liberating the escapement and allowing the upper carbon to descend slowly as described; (2) in combination with a lever above referred to, having two cores acted upon differentially by two solenoids, the one in the lamp and circuit, and the other in a shunt, a third solenoid, which, in case of excessive resistance in the lamp circuit, is brought into and closes the external circuit and maintains it closed.—No. 7599. May 15th, 1890. 8*d.*

CHEMISTRY.

COLOURING MATTERS.—*C. D. Abel, London.* (*The Actien Gesellschaft für Anilin Fabrikation, Berlin, Germany.*)—By the action of one molecule of tetrazoditolyle upon one molecule of α-naphthylamine there results a product:—

$$C_7H_6 - N = N - C_{10}H_6NH_2HCl$$
$$\vert$$
$$C_7H_6 - N = NCl.$$

This diazo compound may, by treating with nitrous acid, be converted into a tetrazo compound which can be combined with phenols, amines, or their sulphur and carbo-acids, so forming colouring matter. Example: 10·9 kilos. of tolidine are converted in the well-known manner into the tetrazo compound; the solution of this is poured into a solution of a salt of 7·5 kilos. of α-naphthylamine. The mixture is allowed to stand for some time and afterwards acidulated with hydrochloric acid and again diazotised by treatment with nitrite of soda; the tetrazo compound formed in this way is combined with 40 kilos. of a soda salt of the α-naphtholdisulpho acid mentioned in the Specification No. 15775 of 1885. After standing for some hours the mixture is boiled, the colouring matter is precipitated by salt, filtered, and dried. This dyes unmordanted cotton a deep blue violet. Claims: (1) The production of colouring matters by combining one molecule of the tetrazo compounds of tolidine, dianisidine, or diphenetidine with one molecule of α-naphthylamine, diazotising the product thus obtained and reacting with this rediazotised compound upon either of the α-naphtholdisulpho acids, described in the Specification No. 15775 of 1885 or No. 4625 of 1888; (2) as new articles of manufacture the colouring matters herein described.—No. 6932. May 5th, 1890. 6*d.*

APPARATUS FOR THE PRODUCTION OF CARBONIC ACID GAS.—*H. H. Lake, London.* (*La Société J. Jay et Jallifier, Lyons, France.*)—A front and side sectional elevation is shown respectively at Figs. 1 and 2 in the annexed illustrations of an apparatus of the above description. The casing A, of enamelled metal, is closed hermetically by a lid B pressed downwards by a screw C as shown, and contains a glass vessel D, perforated at its lower extremity and containing bicarbonate of soda in the form of blocks. This vessel D is supported in the upper part of A by means of a flange as shown, and the lower part thereof projects into a second glass vessel E containing acidulated water. A hollow neck is cast on the lower part of A, through which the upper part of a rod F passes. The lower end of this rod is supported in an indiarubber tube G fixed by a flange to the neck on A, and around which is placed a helical wire and a protecting tube. The interior of this tube G is in connection with the interior of A, so that as the pressure rises in A the tube will be elongated, so allowing the rod F to fall. One end of a weighted lever H is connected to a metal cap on the lower end of

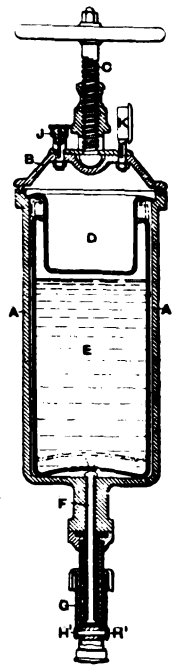

FIG. 1.

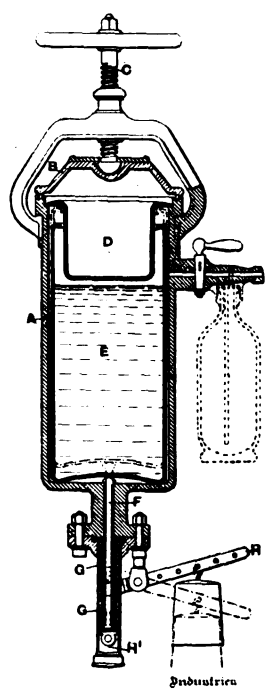

FIG. 2.

G by means of links H^1. It will thus be seen that, when there is no pressure in A, F, and consequently G E, will be forced upwards, so bringing the contents of D and E in contact, which gives rise to a regular disengagement of carbonic acid gas. As, however the pressure rises in A, E will be allowed to fall gradually, so diminishing the quantity of gas disengaged. The usual cock I, safety valve J, and pressure gauge K are connected with A.—Five claims are made.—No. 4473. March 21st, 1890. 8*d.*

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

ORNAMENTAL TURNING LATHE.

THE illustration given herewith represents a 5in. ornamental turning lathe, made by Mr. Henry Milnes, Ingleby Works, Bradford. The bed is 3ft. 6in. long, and is scraped up accurately to a surface plate. The lathe headstocks are of recent design, and the front headstock has a hard steel traversing mandrel bored throughout, working in hard steel bushes. It has a gun-metal cone, with five circles of divisions, forming the following group, viz.:—192, 180, 160, 120, 100. The cone is so marked and figured that it can be read at sight, thus obviating the necessity of counting when used for the purpose of dividing. There is also provided an interpolating index pointer. In addition there are six screw guides and suitable apparatus for screw cutting. The back headstock mandrel is provided with a screw having ten threads to the inch, so that a complete turn of the hand-wheel advances the mandrel one-tenth of an inch. A disc fitted on the hand-wheel is divided into ten, so that in drilling the 100th of an inch may be measured. The lathe centres are of best cast steel, and made conical to fit into the spindles. The lathe comprises a driver chuck, drill chuck, prong chuck, tool board, and drawer of polished mahogany, hand rest fitted with two top rests, strong turned steel crank-shaft with ends hardened and working on hard steel long pointed centres, and easy going treadle motion, double bevel cast-iron fly-wheel, with six speeds, driving bands, and spanners.

The overhead apparatus is mounted on cast-iron bearers, which are bolted firmly to the lathe bed. There are also a long triangular bar, with gun-metal sliding carriage and guide pulleys, a lever and counterbalance weight, steel motion shaft, and speed pulleys. With this design of overhead arrangement it is possible to take in work 15in. long without moving the sliding carriage or the driving pulley. The slide rest for ornamental turning is 12in. long, and is fitted with a gun-metal cradle and stops for use in turning a surface or cylinder. There are also a graduated arc and elevating screw, tool receptacle with two steel screws for regulating the depth of cut, and a gun-metal ring for raising or depressing the height of tool point. The upper slide is fitted with a collar to ensure proper control without the use of a lever. The necks of the mandrel, after being hardened, are ground on the dead centres by a revolving lap. Great care has been taken to ensure easy running both for ordinary turning and for overhead work. There are a variety of fittings designed for this lathe, and altogether it is well designed and neatly finished. The workmanship and materials are, we understand, of the best throughout.

ORNAMENTAL TURNING LATHE.

CONSTRUCTED BY MR. HENRY MILNES, INGLEBY WORKS, BRADFORD.

GENERAL VIEW.

THE NICARAGUA CANAL.

II.

FINAL SURVEY AND PROPOSED ROUTE.

(*Continued from page* 290.)

IN our last article we gave a brief history of the various proposals, surveys, and negotiations relating to the construction of an inter-oceanic canal through the Central American isthmus, chiefly with reference to the Nicaraguan route, up to the date of the final concession to the company who now have the undertaking in hand. We have seen how, after a careful examination of the results of official surveys and estimates, a Commission, appointed by President Grant, unanimously reported in favour of the Nicaraguan scheme. The decision of this Commission was expressed in the following words:—"After a long, careful, and minute study of the several surveys of the various routes across the continent, we unanimously report, that the route known as the Nicaragua route possesses, both for the construction and maintenance of a canal, greater advantages, and offers fewer difficulties, from engineering, commercial, or economical points of view, than any of the other routes shown to be practicable by surveys sufficiently in detail to enable a judgment to be formed of their relative merits."

Of course, the chief *primâ facie* advantage of the Nicaraguan route, and that which caused attention to be directed to it early in the sixteenth century, is the existence of natural waterways over a large proportion of the proposed course, these waterways consisting in the River San Juan and Lake Nicaragua. In connection with this part of our subject, we may here remark—in anticipation of subsequent more detailed particulars—that although the total length of the route as finally decided on is about 169½ miles, of this 121 miles consist of natural waterways, leaving only about 48 miles to be artificially constructed, partly by means of dams and partly by excavation. The existence of Lake Nicaragua and the River San Juan also ensures an abundant supply of water, a very material advantage.

On the chart (Fig. 2) accompanying our first article, the present courses taken by vessels between various ports are compared with those which would be adopted after the construction of the canal, and in this connection the following particulars will be of interest:—

Route.	*Vid* Cape Horn.	*Vid* Cape of Good Hope.	*Vid* Canal.	Distance saved.
Liverpool to	Miles.	Miles.	Miles.	Miles.
San Francisco.....	14,690	—	7,508	7,182
Melbourne	13,352	13,140	12,748	392
Hong Kong.....	18,030	15,051	13,786	1,265
Yokohama	17,529	16,040	12,111	3,929
Valparaiso	9,600	—	7,448	2,152
Sandwich Islands	14,080	—	9,136	4,944
Guayaquil	11,321	—	5,890	5,431
New York to				
San Francisco.....	14,840	—	4,946	9,894
Hong Kong.....	18,180	15,201	11,038	4,163
Yokohama	17,679	16,190	9,363	6,827
Melbourne	13,502	13,290	10,000	3,290
Sandwich Islands	14,230	—	6,388	7,842
Guayaquil	11,471	—	3,053	8,418

The distances given refer to routes taken by slow trading steamers and sailing vessels, and not to those followed by mail and passenger steamers. As regards the advantages to be derived by this country from the use of the proposed canal, it must be remembered that not only the carrying trade between British and foreign ports is conducted in British vessels, but also a very large proportion of the trade of other countries, so that England has, for instance, almost as direct an interest in the reduction of the distances between New York and Hong Kong or San Francisco, as in shortening the routes from the latter places to Liverpool. It seems scarcely creditable to our enterprise, whatever from the prudential point of view may be said in our defence, that although Great Britain has such a preponderating interest in the commerce of the world, not one of the great inter-oceanic canal projects owes its inception to British energy or capital. This is perhaps the more surprising, since on two occasions, at least, to which we incidentally referred in our historical review, the British Government showed its appreciation of the advantages to be derived from a canal through the American isthmus by attempting to acquire territorial rights there.

Intimately associated with the shortening of routes is the question of the traffic to be expected through the canal, but it will be more convenient to consider this later on when dealing with the financial aspects of the undertaking.

During the official survey by the United States Government of the Nicaragua route, which was commenced in March, 1872, and continued until July, 1873, no less than eight different routes from the lake to the Pacific were explored, including that examined by Colonel O. W. Childs, in 1850, from the mouth of the River Lajas, which empties itself into Lake Nicaragua, to Brito, on the Pacific coast, the accuracy of which was confirmed. Childs found the lowest depression in the Cordilleras, between the oceans on either side of the isthmus, to be 152ft. only above sea level, and proposed to take the canal through this. The chief difficulty in the way of the execution of this scheme was the drainage of the valley of the Rio Grande, a problem at that time not satisfactorily solved. On this account certain modifications of the route in question were introduced by the Government surveyors, and a project was finally proposed embodying the following main features:—56·5 miles of lake navigation and 63·02 miles of navigation by the River San Juan, with 61·74 miles of excavated canal, twenty-one locks, and four dams across the San Juan. The total length would thus be 181·26 miles, and the estimated cost was $65,222,147.

Mr. A. G. Menocal, now chief engineer of the company constructing the canal, to whose admirable report we are indebted for much of our information, re-surveyed in 1880 the line adopted by Childs, with the results of re-

Digitized by Google

THE NICARAGUA CANAL.

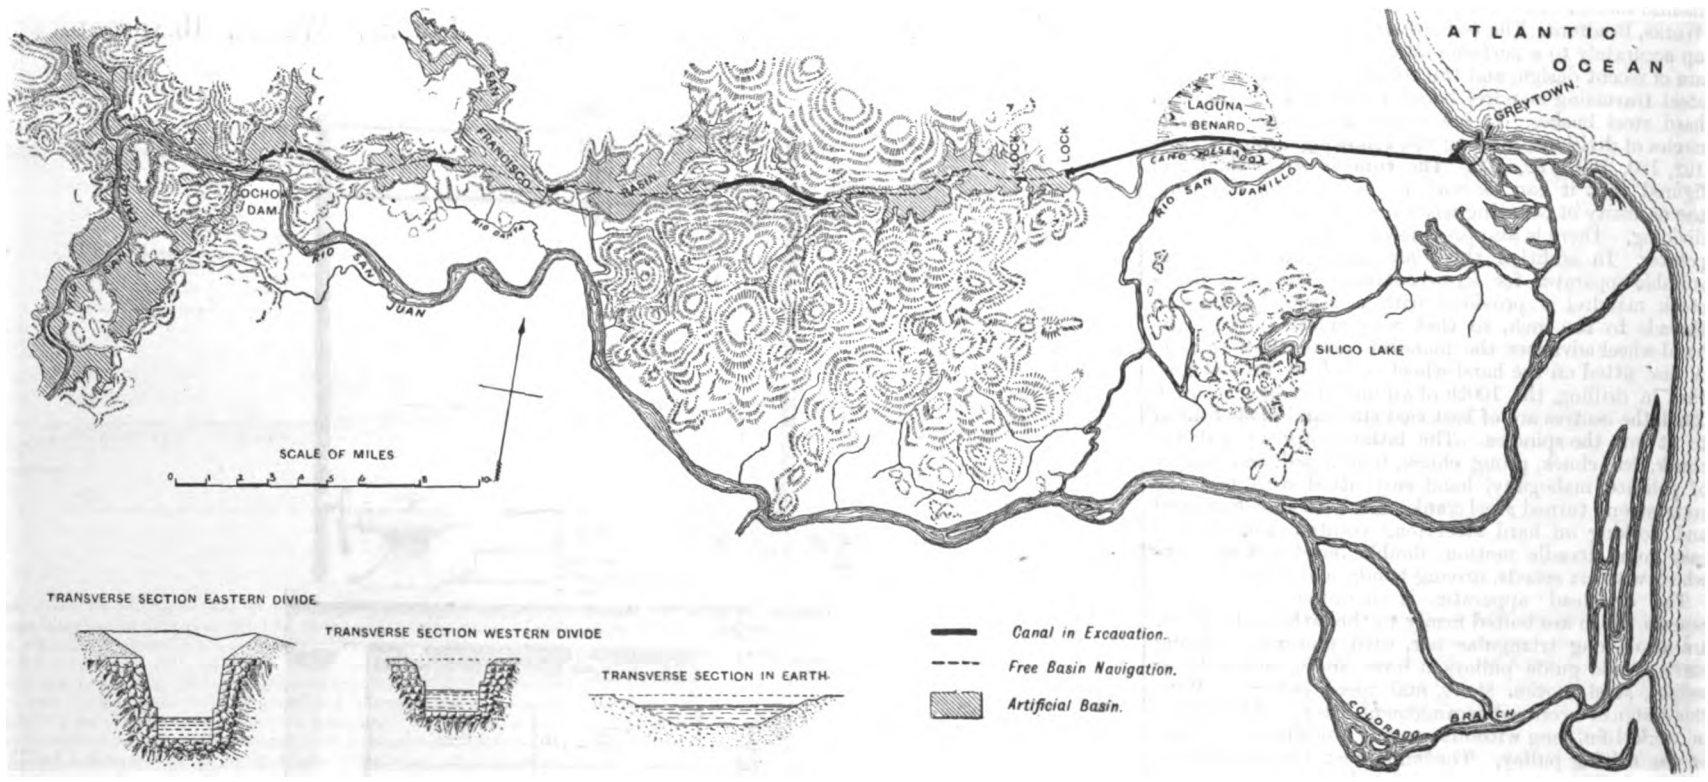

FIG. 3.—EASTERN DIVISION.

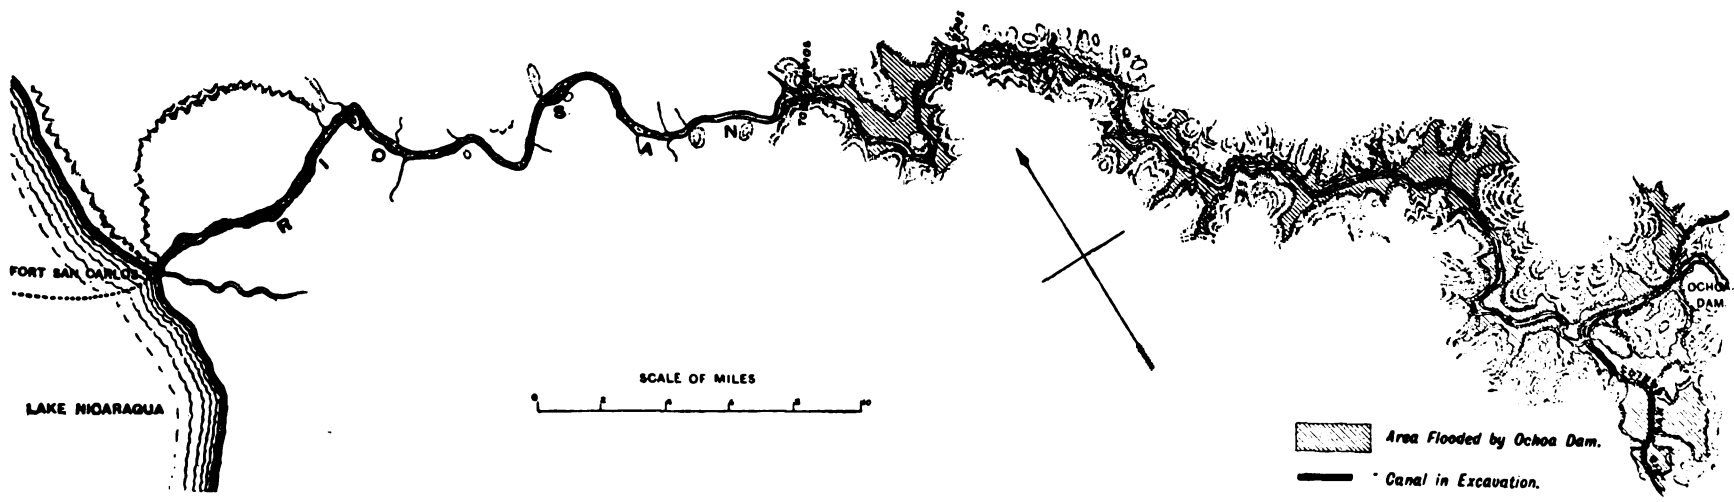

FIG. 4.—SAN JUAN RIVER OR CENTRAL SECTION.

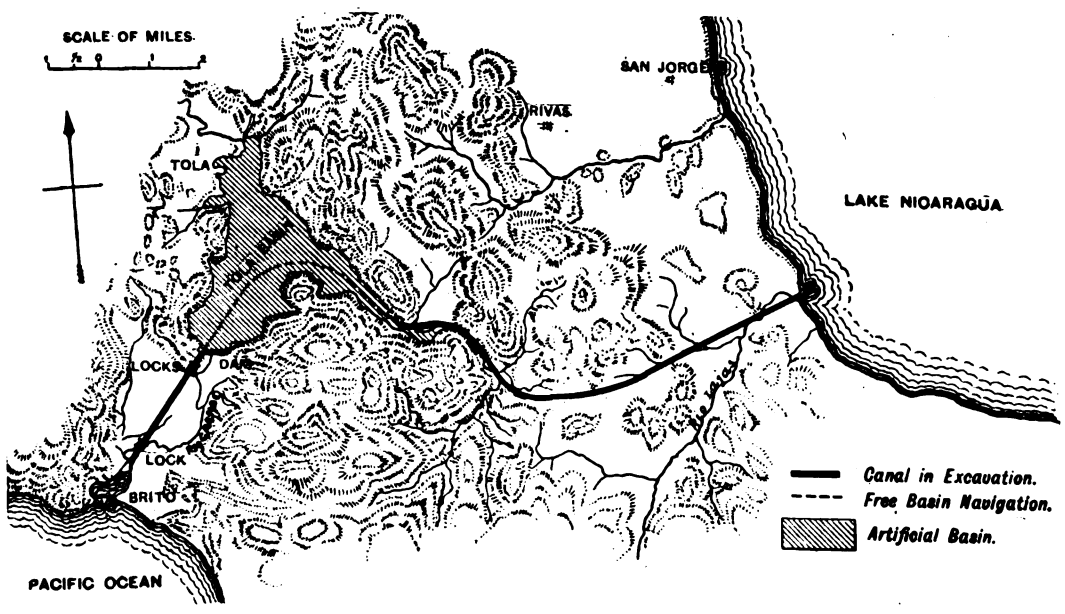

FIG. 5.—WESTERN DIVISION.

ducing the length by 1¼ mile, finding a satisfactory solution of the drainage problem by diverting the course of the Rio Grande, above its junction with the canal, through an artificial channel, and reducing the quantity of excavation required. In 1885 a rectification of the section of the proposed route to the east of Lake Nicaragua was also taken in hand by Mr. Menocal at the instance of the United States Government. This happened previously to the final incorporation of the present company, but subsequently another minutely detailed survey was undertaken, lasting two years and a half, the scope of which may be gathered from the fact that for every mile of final location forty miles of actual instrumental survey were required.

The route finally decided on, after the careful and laborious preliminary studies referred to, starts on the eastern coast at the town of San Juan del Norte, or Greytown, and terminates on the Pacific coast at Brito. All the proposed schemes for a Nicaraguan canal appear to have selected Greytown as the point of departure on the Atlantic, but various termini were suggested on the Pacific. The proposed course of the canal may for convenience be divided into three parts :—First, the eastern division ; secondly, the central or San Juan River section ; and thirdly, the western division.

The eastern division commences at the inner harbour of Greytown and extends to the River San Juan at Ochoa, the central section follows the San Juan River from Ochoa to its confluence with Lake Nicaragua, while the western division comprises that portion between the

Digitized by Google

THE NICARAGUA CANAL.

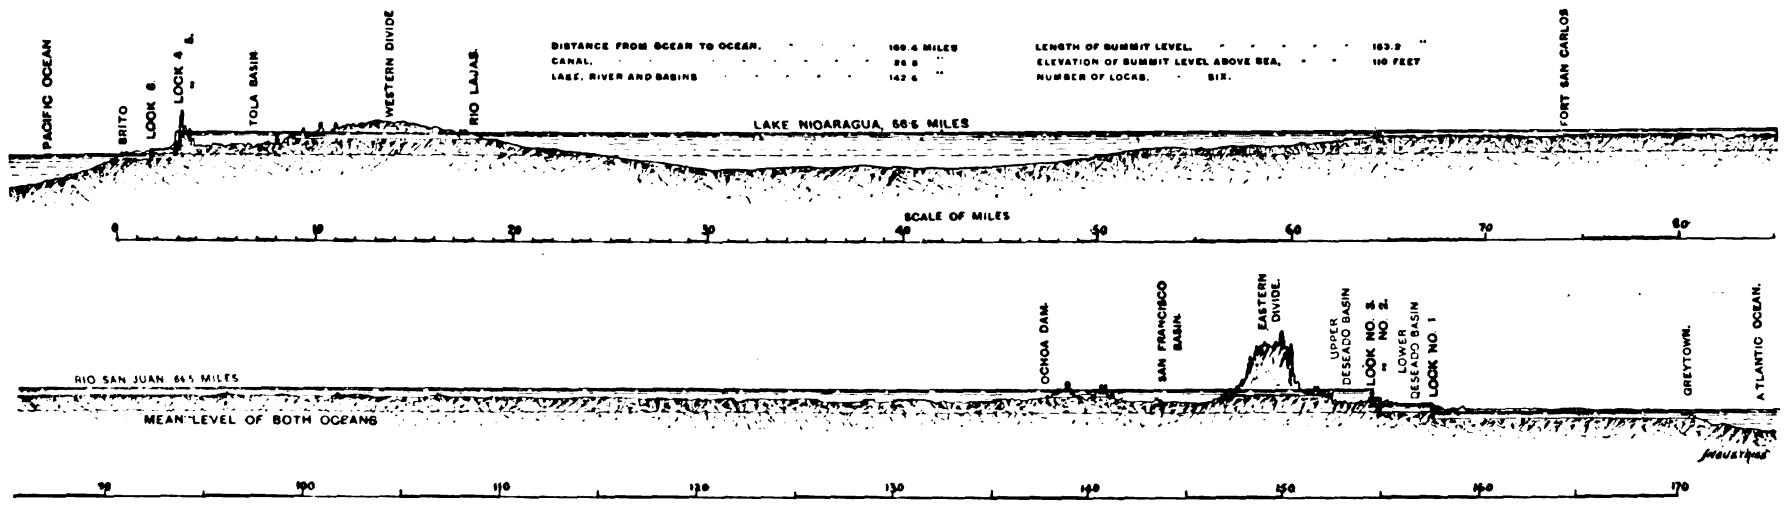

FIG. 6.—DIVIDED PROFILE SHOWING THE WESTERN, CENTRAL, AND EASTERN DIVISIONS OF THE CANAL.

lake and the Pacific. Plans of these divisions are shown in Figs. 3, 4, and 5 respectively. Before proceeding to describe in detail each section of the canal, it should be stated that there will only be six locks in all, three near the eastern and three near the western end. Commencing at the eastern terminus Lock No. 3 is to be only 12¾ miles from Greytown, and Lock No. 4, 2·15 miles from the Pacific port of Brito. Between these two points navigation will be unimpeded. The summit level of the canal will be that of Lake Nicaragua, taken at its mean value of 110ft. above mean sea level.

From the harbour of Greytown the projected canal runs in a westerly direction, with a slight southerly inclination, at sea level, for a distance of 9·297 miles, to Lock No. 1, following for a considerable portion of its length the valley of the Deseado stream, which at certain points will have to be diverted into artificial channels to avoid interference with the canal. Lock No. 1 will have a lift of 30ft., and its dimensions, like that of all the other locks, will be 650ft. by 70ft. From Lock No. 1 to Lock No. 2 the canal continues in the Deseado valley, which will here be partially flooded by the construction of four low embankments in conjunction with weirs for controlling the drainage. Between Lock No. 1 and Lock No. 2 there is an interval of 1·258 miles, and the latter has a lift of 31ft. 1·927 miles further west, and—as before stated—12¾ miles from Greytown, is Lock No. 3, with a lift of 45ft. Above Lock No. 3 the so-called Upper Deseado Basin is formed by an embankment 70ft. in height and 1,050ft. long, connecting the sides of the valley. This basin has a length of over three miles, with a depth of from 30ft. to 70ft., obtained for a distance of 2·590 miles without excavation. The dam is to be built of stone, with earth backing, and will have a weir 600ft. long on the crest. On the south side of the valley, in a gap between the hills, will be a second weir, 800ft. in length. At the western end of the Upper Deseado Basin is the "Eastern Divide," the cutting through which forms the heaviest piece of work on the whole canal, and contains 21 per cent. of the total estimated excavation. The length of the cutting is 2·917 miles, the maximum depth 298ft., and the average depth above the water level 111·2ft.

The material to be removed consists chiefly of solid rock, which will be utilised for building the dams and embankments required in the vicinity. On either side of the ridge an unlimited supply of water power is available for driving all the necessary machinery, while the climate is said to be one of the healthiest in Nicaragua. Fig. 6 represents a divided profile of the whole canal, which, together with the plans already referred to, will assist to make the preceding and subsequent descriptions more clear. On the western side of the ridge of the Eastern Divide another basin will be formed by constructing a series of embankments to close the gaps between the hills surrounding the valley of the San Francisco River and its tributaries. The total length of this, the "San Francisco Basin," will be 11·267 miles, including a length of 1·233 miles wholly, and another of 2·570 miles partly, in excavation. It is claimed that by the creation of basins instead of narrow excavated channels, considerable advantages are secured. In the first place, vessels can travel at full speed, lie at anchor, and pass each other at any point, while the basins immediately above the locks serve as "turn-outs" for ships waiting to enter. In the second place, with reference to the San Francisco Basin, Mr. Menocal says, in his report, "that without it the cut across the 'divide' would be of such proportions as to make the route commercially impracticable and the basin of the Deseado an impossibility." The embankments will be all so formed as to serve as waste weirs for the discharge of surplus water at various points of the basin, and in this manner it is calculated that very ample provision has been made against floods and freshets. The weirs in the basin alone, without taking into account the Deseado dam and weir and the culverts of Lock No. 3, are estimated as capable of discharging 90,200 cubic feet per second, before the water reaches the top of the higher embankments. The total length of what we have called the "Eastern Division" is 31·364 miles.

(To be continued.)

BOILER DEPOSITS.*

Two years ago I had the honour of reading a paper before this Institution on "Boiler Incrustations," in which I traced the formation of the scale, and the causes which led to the precipitation and hardening of the calcic sulphate, calcic carbonate, magnesic hydrate, and other compounds which are usually found to be present, and I pointed out that the scales formed by various kinds of water were so characteristic that one could speak with certainty as to the kind of water from which the incrustation had been formed by an analysis of the scale itself. The analyses given below may be looked upon as typical of the incrustations formed by fresh water, brackish water, and sea water respectively in marine boilers:—

Constituents.	River.	Brackish.	Sea.
Calcic carbonate	75·85	43·65	0·97
Calcic sulphate	3·68	34·78	85·53
Magnesic hydrate	2·56	4·34	3·39
Sodic chloride	0·45	0·56	2·79
Silica	7·66	7·52	1·10
Oxides of iron and alumina	2·96	3·44	0·32
Organic matter	3·64	1·55	trace
Moisture	3·20	4·16	5·90
	100·00	100·00	100·00

From this it is evident we may look upon the incrustation from fresh water as consisting of impure calcic carbonate, whilst that from sea water is impure calcic sulphate, the brackish water from the mouths of rivers yielding, as might be expected, an incrustation in which both these compounds are present in nearly equal quantities.

The importance of these differences in the deposit formed is very great, as it enables the shipowner to arrive at a conclusion as to the treatment that the boilers have received during the voyage, by examination and analysis of the scale which those boilers contained. Taking, for instance, the case of a ship which uses fresh water both for filling and make-up, it is manifest that on her return to port the scale should be very slight and should consist mainly of calcic carbonate; whilst, if the scale exceeds ⅛in. and shows a preponderance of calcic sulphate, it is manifest that such scale could only have been formed by sea water, either leaking in from faulty condensers or being deliberately fed into the boilers. The reception you were kind enough to give that paper, and the frequency with which it has been quoted since, lead me to hope that, in continuing and completing the subject, I shall be performing a not unwelcome task. So far the deposits taken into consideratton have been those formed from the impurities natural to the water itself; but with the introduction of high-pressure steam a new and highly dangerous form of deposit has added to the trouble of the marine engineer.

As early as 1878 the collapse of the furnaces of the boilers of the s.s. "Ban Righ" and a similar misadventure in the screw tug "Ich Dien," with no apparent cause to bring about the damage, caused some attention to be paid in marine circles to the action which had taken place, and the only clue to be found was that a certain amount of oily deposit had formed on the tops of the furnaces, and experiments made by Mr. Dunlop, of Port Glasgow, led to the conclusion that this oil, which had distilled into the boiler from the lubricants used in the cylinder, was so bad a conductor of heat that its formation on the plates allowed them to get superheated, with the result that they were unable to withstand the pressure of steam existing in the boiler, and in this way brought about the collapse. Similar cases of collapse became frequent after that date, no less than thirty vessels being disabled from this cause during the last few years.

The first case which came under my notice, in which damage to boilers had arisen from this cause, was the case of a large ocean steamer, and through the kindness of Mr. Milton, Chief Superintendent Engineer of Lloyd's, I was able to obtain samples of deposit from all parts of the boilers, and full particulars of the case. The steamer was a large one trading between Liverpool and Boston, averaged twelve days on the voyage, and was fitted with ordinary compound engines. She had three double-ended boilers, with three plain furnaces at each end, and three combustion chambers in each boiler. The furnaces were plain in one length and connected at the back end to the tube plates, being flanged up inside the chamber, whilst the front end plate is flanged inwards on to the furnace crowns. The furnace crown was ⅜in. plate, and the front bottom plate 11/16in., the working pressure being 80lb. The boilers are about five and a half years old, and have always been refilled with fresh water at the end of each run, both at Boston and Liverpool; whilst, as a rule, the waste on the voyage was made up by the use of about 70 tons of fresh water, but during the last voyage sea water was used for this purpose. Every four hours whilst under steam 4lb. of soda crystals were put in the hot well, making about 2 cwt. during the run, the total capacity of the boilers being about 81 tons. For lubricating purposes about seven pints per day of valvoline were used in the cylinders.

When in port the boilers were allowed to cool down, and the water was run off, and they were swept down with stiff brushes, and were afterwards sluiced out with a hose shortly before being refilled with fresh water. No trouble occurred with the boilers until five voyages before the final collapse, when some of the furnaces began to creep in; they were stiffened with rings and stays, and on the succeeding voyages the whole of the furnaces got out of shape, one after another. Examination of these boilers clearly showed that they had never been very heavily scaled, as in parts of the boiler where it would have been impossible to get at them to clear them out, no signs of heavy incrustation were to be found, and the absence of marks of scaling tools also showed that they had never been allowed to get very dirty. On the furnace crowns, where they had collapsed, there was only a slight white scale, not more than 1/32in. in thickness, whilst on the bottom of the furnaces there was a brown oily deposit 1/16in. in thickness, which in other parts of the boilers increased to between ⅛in. and 3/16in. I obtained from Mr. Milton samples of the thin scale from the top furnaces, and of the deposit from various parts of the boiler, and also specimens of cut-out portions of the boiler plates, Liverpool water, valvoline, and soda crystals put into feed water, and of all these analyses were made as given below.

I.—VALVOLINE.

The valvoline on analysis gave:—

Vegetable and animal oil	*nil*
Mineral oil	100 per cent.
Acids (free)	*nil*
Boiling point	371° C
Specific gravity	·889

II.—SCALE FROM FURNACE.

	From Top.	From Below.
Calcic sulphate	84·87	59·11
Calcic carbonate	5·90	6·07
Magnesic hydrate	2·83	11·29
Iron, alumina, and silica	2·37	2·85
Organic matter and oil	3·23	19·54
Moisture	0·80	1·14
Alkalies	*nil*	*nil*
	100·00	100·00

* Paper read by Professor Vivian B. Lewes before the Institution of Naval Architects on the 19th ult.

III.—Deposit from Tubes.

	Scale on Tubes.	Deposit above the Scale.
Calcic sulphate	50·92	11·60
Calcic carbonate	4·18	0·82
Magnesic hydrate	14·12	22·21
Iron, alumina, silica, &c.	7·47	9·14
Organic matter and oil	21·06	50·20
Moisture	1·17	4·23
Alkalies	1·08	1·80
	100·00	100·00

IV.—Deposit from Bottom of Boiler.

Calcic sulphate	22·52
Calcic carbonate	*nil*
Magnesic hydrate	7·09
Silica, alumina, and iron	34·85
Organic matter and oil	27·95
Moisture	5·79
Alkalies	1·80
	100·00

The boiler plates were as good as the day they were put in, and showed no structural signs of having undergone any change, whilst the analyses of the Liverpool water and the soda crystals used showed that they could have taken no part in the action which had led to collapse.

On careful examination of the organic matter and oil present in these deposits, it was found that quite one-half of it was "valvoline," in an unchanged condition, which had collected round small particles of calcic sulphate. A consideration of these analyses, at first sight, yields no clue as to the cause of the collapse, the scale upon the furnace tops being not only free from oil, but perfectly harmless both in quantity and quality; but, on going more deeply into the question, it is evident that this scale cannot be in the condition in which it was originally formed, as the deposits from both top and bottom of tubes, from the bottom of the furnaces, and from the shell of the boiler, are all rich in oily matter; and it is impossible that, during this deposition, the furnace tops could have escaped whilst all other parts of the boiler became coated with it. Experiments, however, reveal the actions which had been at work and led to the formation of the deposit, and its absence upon the injured portions of the plates. The pressure at which the boilers were worked was 80lb., corresponding to a temperature of 155° C., or 311° F., which is so far below the boiling point of the valvoline that it was evident that it had not distilled over in the ordinary way, and experiments were made to see if it could be distilled in steam at a lower temperature. A retort containing valvoline was carefully heated over a sand bath, its temperature being ascertained by a thermometer, and steam was then blown through it, with the result that at 248° F. or 120° C. the steam became "greasy" and the oil commenced to pass over with it.

This experiment is, I think, important, as it shows that, in testing the capabilities of a lubricant, the fact that it has a boiling point well above the temperature of the steam is no guarantee that none of it will find its way into the boiler. Having thus entered the boiler, the minute globules of oil, if in great quantity, coalesce to form an oily scum on the surface of the water, or, if present in smaller quantities, remain as separate drops; but show no tendency to sink, as, their specific gravity being ·889, they are lighter than the water, and the difference in the gravity is probably even greater at the temperature existing in the boiler. Slowly, however, they come in contact with small particles of calcic sulphate and other solids separating from the water, and, sticking to them, they gradually coat the particles with a covering of oil, which in time enables the particles to cling together or to the surfaces which they come in contact with. These solid particles of calcic carbonate, calcic sulphate, &c., are heavier than the water, and, as the oil becomes more and more loaded with them, a point is reached at which they have the same specific gravity as the water, and then the particles rise and fall with the convection currents which are going on in the water, and stick to any surface with which they come in contact, in this way depositing themselves, not as in common boiler incrustations, where they are chiefly on the upper surfaces, but quite as much on the under sides of the tubes as on the top, their position being regulated by whether they come in contact with the surface whilst descending or ascending.

The deposit so formed is a wonderful non-conductor of heat, and also, from its oily surface, tends to prevent intimate contact between itself and the water. On the crown of the furnaces this soon leads to overheating of the plates, and the deposit begins to decompose by the heat, the lower layer in contact with the hot plates giving off various gases which blow the greasy layer, ordinarily only $\frac{1}{16}$in. in thickness, up to a spongy leathery mass often $\frac{1}{4}$in. thick, which, because of its porosity, is an even better non-conductor of heat than before, and the plate becomes heated to redness, and, being unable to withstand the pressure of steam, collapses. During the last stages of this overheating, however, the temperature has risen to such a point that the organic matter, oil, &c., present in the deposit burns away, or, more properly speaking, is distilled off, leaving behind, as an apparently harmless deposit, the solid particles round which it had originally formed. Such a deposit is much more likely to be produced with boilers containing fresh or distilled water, as the low density of the liquid enables the oily matter to settle more quickly, whilst with a strongly saline solution it is very doubtful if this sinking point would ever be reached; it is evident also that, when oil has found its way into the boiler, and is causing a greasy scum on the surface, the most fatal thing that can be done is to blow off the boilers without first using the scum cocks, because, as the water sinks, so the scum clings to the tops of the furnaces and other surfaces with which it comes in contact, and, on again filling up with fresh water, it still remains there, causing rapid collapse.

A very remarkable instance of this is to be found in the case of a large vessel in the Eastern trade, in the boilers of which an oil scum had formed. The ship having to stop some days at Gibraltar, the engineer took the opportunity of blowing out his boilers and refilling with fresh water, with the result that, before he had been ten hours under steam, the whole of the furnaces had come in. Under some conditions the oil-coated particles coalesce and form a sort of floating pancake, which, sinking, forms a patch on the crown of the furnaces at one particular spot, and under these conditions the general result is the formation of a "pocket."

A curious fact, which is worthy of attention, is that in most of these oily deposits copper is to be found in considerable quantity. In an analysis of deposit from the furnace of a vessel in which a "pocket" had formed from the above-mentioned cause, the scale showed, as in the case already cited, no reasonable cause for the injury at the damaged part of the boiler, whilst the deposit from the underside of the furnace tubes showed clearly the presence of large quantities of oil matters, which were partly combined with copper:—

Constituents.	Scale.	Deposit.
Calcic sulphate	90·354	1·02
Calcic carbonate	1·200	*nil*
Ferric oxide, Oxide of alumina	3·200	56·90, 2·30
Oxide of copper	*nil*	1·90
Magnesic hydrate	2·821	1·80
Organic matter, Oil	1·600	10·46, 17·84
Sand, &c.	0·825	7·78
	100·000	100·00

It is a fact that even mineral oils have a considerable solvent action upon copper and its alloys, and it is evident that the copper in the oily deposits has been obtained from the fittings of the cylinder and condenser. Fortunately, this copper is so well protected by oil that in most cases it is extremely unlikely to come in contact with, and deposit on, the metal of the boiler; but, if it did, very serious galvanic mischief would be the result.

(To be continued.)

THE MANCHESTER SHIP CANAL.

IV.

On pages 365 and 372 we give four further illustrations of this work. Figs. 7 and 8 show the Mode Wheel Locks. They are situated about three miles below the Manchester terminus of the canal, and about 33¾ miles from the Eastham entrance, and are the last of the series of locks. The first locks are at Latchford, 20½ miles from Eastham, and raise the level of the water in the canal 14ft. 6in.; the next locks are at Irlam, 27¾ miles from Eastham, and raise the level of the water 16ft.; the next are at Barton, 30½ miles from Eastham, and raise the level of the water 15ft.; and the last locks are the Mode Wheel Locks. With the exception of the Eastham Locks, all the locks are in pairs, the larger lock being 600ft. long by 65ft. wide, and the smaller one 450ft. long by 45ft. wide, all the upper locks being the same size of pairs, and of similar construction, the only difference being in the lifts and in the number of sluices. The 65ft. locks have intermediate gates to cut off 150ft., and the smaller ones cut off 120ft. The large locks have a sluice way in the wall 6ft. by 12ft., with four openings into the dock so as to distribute the discharge; the smaller locks having two sluice ways 4ft. 6in. by 8ft., with four openings in each wall. The sluice ways are lined with blue brick on a brick backing. The walls are built of concrete up to water level, above which they are faced with blue brick and have an 18in. granite fender course near the water line. The sills and roller paths are of granite, with sandstone backing, grooves being left in the end of the walls to receive a temporary dam or a caisson when any repairs are necessary. The wall between the locks is 29ft. 6in. thick, the concrete being in the proportion of 8 to 1 in the body and 4 to 1 in the face of 9in. The depth of water on the sills of the 65ft. locks will be 28ft., and on that of the smaller lock 25ft., the normal depth of the canal being 26ft.

The Mode Wheel Locks may be considered the entrance to the Manchester system of docks, for at this point the width of the canal at the bottom is increased from 120ft. to 171ft. At each of the locks is a series of sluices for passing away the flood waters; they are all 30ft. wide, and are made on Stoney's principle. At Mode Wheel there are four sluices, 30ft. by 13ft. lift; at Barton there are four, 30ft. by 15ft. lift; at Irlam there are five, 30ft. by 16ft. lift, the large area being necessary to take the waters of the various tributaries and streams; at Latchford there are two, 30ft. by 14ft. 6in. lift.

Fig. 9 illustrates the Little Bolton cutting, which is a few yards to the west of Mode Wheel Bridge, and is practically a diversion of the river. This portion is absolutely completed, and was the first to receive the water permanently, although it had previously been filled by the floods bursting in the banks in October, 1889, and in January, 1890, when 65 million gallons of water entered the canal in twenty minutes. When this length was afterwards filled permanently—the flooded water having been pumped out to enable the work to be completed—it took over six hours to raise the water 1ft. in height. It required over 2,000 waggon loads of sandstone and rubble to repair the damaged bank, and, now that the river is permanently diverted into the cutting, the contractor has a large bed into which he can tip his spoil excavated from other parts.

Fig. 10 illustrates the No. 1 Branch Dock at Manchester. At the Manchester terminus the canal branches out into a series of docks, three on the north side of the canal at Pomona, and five on the east and one on the west side at Manchester. The total area of the docks is 114½ acres, with quays 5½ miles long. The walls of the docks are composed of Portland cement concrete in the proportion of six parts broken stone or gravel, two parts of sand, and one part of cement. The face of the walls above the stony course is of blue brick, the fenders and coping are of granite, as are the hollow quoins, sills, culvert faces, &c., all the stones being made to templates at the quarries.

SOCIETY OF ENGINEERS.

At a meeting of this Society on the 6th inst, Mr. W. N. Colam, President, being in the chair, a paper was read by Mr. T. B. Lightfoot, on "A Trial of a Refrigerating Machine on the Linde System." The author described the construction and arrangements of a testing station for refrigerating machines that had recently been built at Munich, and gave the results of a test trial with a refrigerating machine on the Linde system. The station was erected by Linde's Ice Machine Company, Wiesbaden, and the Augsburg Engine Works Company, by agreement with a committee of the Munich Polytechnic Society. The selection of the site and the arrangement and fitting up of the buildings was under the entire control of the committee, and the trials of the machine were also undertaken by the committee, which appointed a special examining commission from its own members and from the staff of the mechanical division of German Polytechnic High Schools. Only those refrigerating machines were allowed to be exhibited and tested which were arranged for cooling brine, and which under normal working—*i.e.*, when reducing the temperature from 28·4 to 23° Fahr.—developed at least 200,000 thermal units per hour with a refrigerator surface of 670 square feet. The results ascertained by the commission comprised: (1) The determination of the efficiency of the refrigerating apparatus; (2) the quantity of steam and cooling water; (3) in addition, the special features of the machines are examined with the view of ascertaining to what extent, if any, they affect the continuous working of the apparatus. Experiments were made at the following brine temperatures:—

Inlet to Refrigerator.		Outlet from Refrigerator.
+ 42·8 Fahr.	.....	+ 37·4 Fahr.
+ 28·4 „	.....	+ 23·0 „
+ 14·0 „	.....	+ 8·6 „
− 0·4 „	.....	− 5·8 „

The arrangements for measuring the feed-water, the quantity of brine, and the quantity of the cooling water were described. In order to enable the feed water to be accurately measured during a trial of short duration, the steam for working the motor was obtained from a secondary generator in which evaporation was produced by steam drawn from an ordinary boiler. In this way fluctuations in the water level were almost entirely eliminated, and by means of a Vernier scale attached to the water gauge the actual water level could, in practice, be read off to within 1-32nd of an inch. The refrigerating effect was ascertained by taking the product of the weight of brine passing through the refrigerator per hour, with its specific heat, and the difference between the inlet and outlet temperatures. The brine was heated to the required extent and returned to the refrigerator.

A series of tests were made with a No. V. (12 ton) refrigerating machine on the Linde system. The plant consisted of a steam engine combined with a double-acting ammonia compressor, an ammonia condenser, and a refrigerator, together with the requisite connections. The dimensions of the principal parts were given in a table. A table was also given showing the results arrived at by the Commission. This table consisted of six parts; the first dealing with the steam engine, the second with the compressor, the third with the refrigerator, the fourth with the ammonia condenser, while the fifth gave the balance between the heat found in the condenser and that abstracted in the refrigerator, plus the thermal equivalent of the indicated horse-power in the compressor, and the sixth the actual refrigerator duty reduced to per pound of feed water, and per 1 h.p. in the steam engine.

PUBLIC WORKS IN ECUADOR.

The Guayaquil waterworks have been continued slowly throughout the year 1890, but they have not yet been completed, owing to the loss of two steamers that were conveying the tubes for the section from Aqua Clara to Duran. It is expected that these works will be terminated early this year, as only two more vessels with tubes are awaited in order to supply water to the city.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 14th April, 1891.

Iron.—The Paris market remains very firm, though there is some difficulty in securing the augmented prices lately agreed upon by the merchants—viz., 136s. 6d. per ton for bars, and 144s. 6d. per ton for joists. Buyers are, however, forced to give these prices, as the dealers, taking a hint from the ironmasters, have unanimously resolved not to undersell each other, and in future the prices fixed upon at their meetings will be strictly adhered to. On the other hand, manufacturers are inclined to raise their prices; at a recent meeting of forge owners in the North it was decided to raise the price of iron delivered at Paris to 124s. 6d. the ton. At the last meeting of the Paris Municipal Council a scheme for an aqueduct was adopted, which, taking into account the earthwork, masonry, and cast-iron work, besides the water pipe itself, which is to be of steel, will entail an outlay of over 5,000,000fr. At the same meeting it was decided to immediately commence building the Célestin barracks, which will cost about 500,000fr. As we have before stated, many of the railway companies have given large orders for rolling stock since the commencement of the year, the value of which is now estimated to amount to over one million sterling. This abnormal demand for carriages may be partly accounted for by a desire on the part of the companies to be ready for the reductions in passenger fares, which are to come into force in 1892, when a large increase in the number of third-class passengers is expected. In the Meurthe-et-Moselle district the resolution lately taken at a meeting of foundry owners, to reduce the output if necessary, in order to augment the value of the metal, is coming into effect. The following is a rough estimate of the orders now in course of execution in the North district:—Denain et Anzin, 50,000 tons; la Providence, 40,000 tons; Nord-Est, 35,000 tons; the Hauts Fourneaux de Maubeuge, 30,000 tons; Ferry-Curicque, 8,000 tons; J. Sirot, 6,500 tons; C. Sirot, 6,000 tons; Lesaffre, 6,000 tons; V. Dumont, 6,000 tons; Doremieux, 5,000 tons; G. Dumont, 4,000 tons; and the forges of La Sambre, 4,000 tons.

Launches of War Vessels.—On the 9th inst. the cruiser "Zaragota," built by the company of the Forges et Chantiers de la Méditerranée for the Mexican Government, was launched at Havre. This vessel is built of steel, and has a displacement of 1,200 tons; her engines are of 1,300 h.p., and she is expected to attain a speed of 13 knots an hour. The armament consists of two 12cm. guns, two quick-firing 57mm., and two 37mm. machine guns. This vessel is destined for the service of the Mexican naval school. Another torpedo despatch boat, the "Wattignies," was launched last week at Rochefort. This vessel has been built from the plans of M. Bussy, member of the Institute. The "Wattignies" is built of steel, and has two screw propellers; she is 232ft. 9in. long over all by 29ft. 1in. beam, and has a displacement of 1,310 tons. The indicated horse-power of her engines is 4,000, and her speed 18 knots. Her armament will consist of five 10c.m. and two 65mm. quick-firing guns, four 37 mm. revolver guns, and four torpedo tubes. She was commenced in October, 1889, and the total cost, including armament, will amount to 3,167,185fr. The torpedo boat "Le Levrier" was launched recently at Lorient Arsenal, Morbihan. Its dimensions are:—Displacement, 150 tons; length, over all, 196ft. 9in.; beam, 23ft.; depth, 10ft. 6in. The two screw propellers are driven by independent engines of 2,200 h.p., and the speed is estimated at 18·5 knots per hour. The vessel will carry one 65 mm. and three 47 mm. quick-firing guns, two machine guns, and four torpedo tubes. Another vessel of the same type, the "Leger," is on the stocks at Lorient, and nearly ready for launching.

BERLIN, 13th April, 1891.

International Exhibition in Berlin.—Preliminary arrangements for the holding of a large International Exhibition in Berlin were being discussed last month, and the proposal has now advanced a further stage. The industrial societies, which combined together to make the Berlin Trades Exhibition of 1879 a success, are considering the project of the holding of a large exhibition in Berlin in the year 1895. These united societies consider the chief scope of the proposed exhibition should be that of a large general German Exhibition. The important Union for the Promotion of Industrial Progress, which numbers among its members the principal State officials and representatives of the chief industries in the Empire, are, however, in favour of an International Exhibition. A committee has been formed to take the proposal into further consideration. The Government has expressed its willingness to support the Exhibition, in the event of its being taken up by the principal industries of the country, and the project is therefore likely to be brought to a successful issue.

The Baltic Ship Canal.—A canal of considerable importance to traders with the Baltic was opened recently. The canal, which runs from Kiel Bay to the mouth of the Elbe, crosses Schleswig-Holstein by way of Rendsburg, and has a total length of 61 miles. The surface width is 186ft., sloping down to 85ft. at the bottom, with a depth of 28ft. The canal was commenced four years ago, and, it is estimated, will reduce the time of transit from Kiel Bay to the Elbe to something like eight hours.

VIENNA, 13th April, 1891.

The Iron Market.—The state of the iron market shows a constant tendency to improve. The trade in material for building purposes is satisfactory, and the prospect for this year is very good. Agricultural machines and tools are in much request, and manufactories are briskly employed in trying to satisfy the demand. The manufacturers of all sorts of railway material are especially busy. At the end of February there were nearly 500 kilometres of railways in course of construction in Austria, chiefly for the Austro-Hungarian State Railway, the Carl-Ludwig Railway, and the larger local railway companies. Two thousand workmen were employed at that date.—The negotiations for a commercial treaty with Germany are still being prolonged, and trade will be carried on for some further time on the basis of existing agreements between the syndicates. The making of the treaty is likely to cause the syndicates to make new arrangements.

The Coal Market.—The coal market still continues extremely brisk, and the opening of traffic on the Elbe has given trade a considerable impulse. At a recent general meeting of the Brux Coal Mining Company the increase of the share capital by 3½ million florins was announced to have been successfully carried out, and regret was expressed at the loss of several lives in the Anna Mine disaster. The production, as shown by the sales at the company's mines in Tschausch, Dux, Teplitz, and Billin, amounted during the past year to 1·6 million tons, as compared with 1·15 million tons in the previous year. The net profits amount to 481,616fl., and a dividend of 8 per cent. will be paid. The Brux Coal Mining Company is negotiating with the Count of Westphalla for the purchase of his coal mines at Aussig. The price demanded is four million gulden. At a general meeting of the Industrial Coal Company the report showed that many accidents had taken place during the past year, and the production was therefore less than during the previous year. The sale of coal, however, amounted to 157,119 tons. In the year 1890, 681,638 tons of coal were forwarded along the Aussig-Teplitz Railway. The number of waggons despatched for the Elbe traffic was the largest recorded since the opening of the railway, and amounted to 163,765.

Statistics of Imports and Exports.—The Ministry of Commerce has collected some exact statistics with regard to the import and export trade, and the following results have been published for the month of January. The figures show the amount in 100 kilogrammes:—

	Imports.		Exports.
Sugar	129	..	150,658
Wood, charcoal	2,814,678	...	6,856,874
Minerals	154,168	...	426,030
Mineral oil and brown coal	82,390	...	2,214
Cottons, yarns, and webs	124,145	...	10,178
Flax, hemp, and jute	62,673	...	14,307
Glass	2,242	...	24,954
Iron	44,881	...	25,935

BRUSSELS, 14th April, 1891.

The Iron Market.—The market is almost inactive, and there few orders from abroad. The Government is criticised for not taking advantage of the sluggish state of the market to renew the rolling stock on the railways. Old orders are being worked off, and there are no signs of returning animation in the market.

The Coal Market.—In the important contract which the Belgian Government awarded on the 7th inst., the price of coal was higher by 1fr. than was expected, but it seems unlikely that the present firm tone will be maintained. The supply much exceeded the demand, and the abundance of offers showed the difficulty in finding a market for the present production. The prices of both coarse and close burning coal were not below those accepted in open market, and the importance of the contract is an additional ground of confidence. The maintenance of a firm tone is due to the coal owners' agreement not to yield to the demands of iron masters. In view of this agreement the Minister may possibly refuse to ratify the award of the 7th inst. The demand for universal suffrage might possibly lead to strikes among the workmen, which would be aggravated by questions of salary and length of hours of labour.

The Glass Trade.—The syndicate is receiving a steady supply of orders, but there is no change in prices. The demand is only moderate, and the situation is rather unsatisfactory for manufacturers. The export of glass to Columbia is likely to develop. Makers should take advantage of this outlet for trade, which is at present worked only by agents of the Hanse towns.

Electric Lighting at Antwerp.—Some years ago the General Electrical Company of Brussels made efforts to erect a central station at Antwerp, and considerable preparations were made by the erection of a workshop and by an order for cables, whilst connections had already been made with many houses. The gas company then restrained the electrical company from interfering with its monopoly. In consequence of protracted litigation the latter company was obliged to liquidate its affairs, and attempts were made without success to sell the property of the company. The project of electric lighting seems likely to be revived by an agreement between the two companies.

A New Electric Battery.—A company, named "The Economical Electrical Company," has been formed, in order to manufacture the primary battery invented by M. Buffet. The battery has an almost absolute constancy, a large capacity, and the value of the waste products is a large proportion of that of the original materials. These waste products consist of oxide of zinc, and of a liquid which can be easily transformed into an excellent chemical manure. Some extraordinary accounts of the performance of the battery have been published, but a more moderate estimate has been made by M. Lucien.

Gas Manufacture.—The managers of the principal gas works in Belgium and the North of France met on the 10th inst., at Brussels, to decide what course to adopt in view of the price of coal and coke and the sale of waste products.—On the 11th inst. a lecture was given at the Exhibition of the Belgian Gasfitters' trade by Mr. Aerts, manager of the Brussels Gasworks. The author commented on the various systems of lighting and heating recommended by the Association of Gasfitters, and referred to the Wenham and the gaso-multiplex lamps. The lecturer also spoke of the system of ventilation recently installed by Mr. Bandsept for the Association of Gasfitters.

Exhibition at Spa.—An International Exhibition of Hygiene and Sport is to be held at Spa during the present year. The Exhibition will be open for a period of two months—*i.e.*, from August 1st to September 30th—and will comprise the following sections:—Public and industrial hygiene, the hygiene of food and dwellings, sport, racing, hunting, fishing, shooting, cycling, and yachting. Intending exhibitors should apply to the Secretary of the Exhibition, M. C. Goffin, Avenue du Marteau 41, Spa.

DÜSSELDORF, 14th April, 1891.

The Iron and Steel Market.—The pig iron market continues dull; prices show a downward tendency in spite of the fact that the stocks of pig iron are not increasing. The production of the Rhenish-Westphalian blast furnaces has been reduced by about 20 per cent. as compared with the previous year. Best Westphalian forge pig iron is quoted at from 52 to 53½ marks, best foundry and hematite at 71 marks, foundry No. 3 at 60 marks, Thomas pig iron at 48 marks. Rolled merchant iron is selling at 125 marks on the average. The business in girders is suffering a heavy depression, and there has been a sudden reduction in price of about 15 marks, which is an immediate consequence of an arrangement made between the German and Austrian syndicates.

The Coal Market.—This market, in marked contrast to the iron and steel market, continues in a very brisk condition. The production of the Westphalian collieries was 7,527,390 metric tons in the first quarter of this year, against 7,344,770 tons in the same period of the previous year, an increase of about 2½ per cent. The contracts awarded at Magdeburg show that the price for 250,000 tons coal for locomotive engines was 10½ marks, lump coals 12 marks per ton, and briquettes 13½ marks per ton at the mine. The report that the United States are beginning to ship coals to Bremen and Hamburg has not had any important influence on the German coal market. One steamer, belonging to Hamburg, is now bringing over 3,500 tons of coal, and the steamers of the Lloyd line, trading with Bremen, are said to bring over 1,000 tons each. As, however, American coal costs at American ports about 12 marks per ton, and as the freight by sea is at least 5½ marks, the price of American coal c.i.f. Hamburg would be 17½ marks, whereas the Westphalian collieries are ready to sell at 14½ marks c.i.f. Hamburg.

The American Cutlery Trade and German Workmen.—A New York manufacturer has made arrangements with a large number of workmen skilled in the manufacture of cutlery to go across the Atlantic. They will obtain a free passage and high wages. This is a result of the McKinley Act.

The Atlantic Mails.—The steamers which carry the mails between Bremen, Southampton, and New York are to have an official of the post office on board for the purpose of sorting the letters and parcels, so that they may be forwarded to their destination immediately after the arrival of the mail. The "Havel," which sailed last week, was the first vessel to try the new arrangement.

Discovery of Potassium Salts at Duderstadt.—It is reported that a discovery of potassium salts has lately been made at Duderstadt. Borings are to be made at once by Messrs. Nitschke & Hübner, of Brunswick, on behalf of a syndicate of Westphalian firms. The first boring will be made on the south side of the Sulberg, at a distance of a quarter of a mile from the city. It is expected by geologists that sodium salts also will be found in the Trias at Duderstadt, and a workable quantity of "Abraumsalz." This would be at a depth of from 300 to 400 metres, and the boring will be done at the rate of about 100 metres per month.

AMSTERDAM, 13th April, 1891.

The Sugar Industry in Holland.—The First Chamber of the States-General has followed the example of the Second Chamber by adopting the Government Bill which compels beet sugar manufacturers to pay a supplementary tax if the sugar excise should yield less than 8½ million guilders. The measure is supported by the Government on the ground that the manufacturers are at present making too great a profit out of the raw material, but this contention has not done away with the serious objections raised against the Bill, principally by the growers of beet-root, who argue, not without reason, that it is they, and

Digitized by Google

not the manufacturers of the beet sugar, who will have to pay the supplementary tax. This measure has already caused a rise in the price of the raw material and in rent, both of which must co-operate to restrict the growing of beetroot.

THE BLITONG TIN COMPANY.—The main provisions of the proposed agreement between the Government and the Blitong Tin Company are that the concession is to be extended to the year 1927, and that the State shall receive 5½ per cent. on the gross yield of the annual output. Should the net profit in any one year rise above 350,000 guilders, the Government will be entitled to one-half of such profit. In the case of an export duty on tin, the said 350,000 guilders will be increased by the yield of such duty.

NEW CHEMICAL COMPANY.—The prospectus has been issued of the Chemical Manufacturing Company at Roermond, in the province of Limburg, formed with a capital of 200,000 guilders, in shares and 5 per cent. bonds, in equal moieties, for the purpose of acquiring and working the chemical factories of Dr. A. Haagen. The chief manufacture is that of Prussian blue and cyanide of potassium. The prospectus states that it is intended to manufacture at least 250,000 kilogrammes of cyanide of potassium annually, 100,000 to serve in the manufacture of 80,000 kilogrammes of Prussian blue and 150,000 kilogrammes to be brought to market in Holland, Germany, and England. It is claimed that the Haagen process of manufacture is superior in many ways to other systems of production.

THE NETHERLAND AMERICAN STEAM NAVIGATION COMPANY.—In 1890 the company did badly, chiefly owing to the Argentine crisis, which has crippled that part of the company's business. No dividend will be paid, and there is a deficiency or loss of working of 3,000,000 guilders.

STOCKHOLM, 11TH APRIL, 1891.

SWEDISH COAL.—The anthracite coal industry of Sweden, which is in the hands of seven operating companies only, greatly improved in the year 1889. The production for the five years ending with 1889 was as follows:—In 1885, 239,356 tons; 1886, 234,203; 1887, 232,398; 1888, 232,383; and in 1889, 256,628 tons. In 1889 some 5,000 persons were employed in and about the mines, and only one life was lost through accident. At present but a small portion of the deposits are being worked, though a far more extensive development is expected to be made within a short time. The coal is found only in the extreme south of Sweden, in the province of Scania. The coals are of excellent quality for steam and similar uses, but being of the anthracite quality, and the mines being too distant from the iron districts, they cannot be expected to figure very largely in the iron industry.

THE HALDA WATCH MANUFACTORY.—An industry, which seems capable of extension and likely to prove remunerative, is the manufacture of watches at Halda. A few years ago only hand power was used, but the installation of steam power when completed will work about 150 different machine tools. In the main hall are sixty machine tools, many of these having been invented and constructed at the works.

NEW STEAMSHIP COMPANY.—A new steamship company has been formed at Oscarhamn, and a steamer has been ordered from the Motala Shipbuilding Company, which has taken shares in the new company. The steamer is to cost 75,000kr., and is to be ready by September 20th.

THE SVARTVIK SAW MILLS.—The Svartvik saw mills and forests have been sold by the Svartvik Aktiebolag to a syndicate of merchants in Sundsvall for 3,000,000kr. During 1889 the shipments amounted to 8,271 standards planks and battens, 4,550 standards boards, and 4,253 standards planed boards.

ELECTRIC LIGHT ON BOARD THE "GÖTA."—The new Swedish warship, the "Göta," has now been fitted with electric light, which has been installed by the firm of Messrs. Luth & Rosén, Stockholm. The installation consists of 150 incandescent lamps, each 16 c.p. Power is furnished by a vertical engine of 25 h.p., running at 400 revolutions per minute. Electricity is also used for projectors, of which there are four, each lamp requiring a current of about 60 amperes, and giving about 50,000 candle-power. These projectors are worked by two engines, each of 30 h.p.

COPENHAGEN, 11TH APRIL, 1891.

THE UNITED STEAMSHIP COMPANY.—The United Steamship Company, Copenhagen, has a fleet of 101 steamers. The profits during 1890 amounted to 1,889,635kr. against 2,952,044kr. during 1889, a result which can hardly be called satisfactory. The company is extending its business and increasing its fleet, and is altogether well managed. The gross profits for last year amounted to 13,767,453kr., the profits on commissions were 391,071kr., and 170,976kr. were carried forward from last year. The expenses were as follows:—Repairs, 873,212kr.; working expenses 10,521,348kr.; insurance, 250,291kr.; managing expenses, 307,707kr,; interest, 316,328kr. The surplus on the working has been appropriated in the following manner:—1,497,371kr., or 5 per cent. of the value of the ships, was added to the reserve fund, 267,758kr. were added to the insurance account, and various smaller sums were written off on other accounts, leaving an available balance of only 90,813kr., which, with the amount carried forward from previous year, amounted to 261,790kr. The shareholders received a dividend of 3 per cent., which represents 240,000kr.

THE GREAT NORTHERN TELEGRAPH COMPANY.—The net profits of the Great Northern Company amount to the sum of 4,303,891kr. for last year. Of this sum 675,000kr. are used for interest and sinking fund of debentures. It is proposed to give the shareholders a dividend of about 8·6 per cent., representing a sum of 2,325,000kr., 1,200,000kr. to be added to the reserve fund, 50,000kr. to the pension fund, 27,050kr. to the Board as tontine, and the balance to be carried forward to next year.

MADRID, 13TH APRIL, 1891.

SHALE IN ASTURIAS.—Some concessions for working bituminous shales in Asturias have been granted to a French mining engineer at Gijon, who acts as French commercial agent by appointment of the Government. Scotchmen, who are so well acquainted with this manufacture, might profitably turn their attention to shale, since oils produced in this country can be sold for three times as great a price as can be obtained in England

PHOSPHATES AT NAVALMORAL DE LA MATA.—This district, in the opinion of some competent engineers, is likely to give an important output of phosphates, though it has not yet been shown by actual working that the raising of the phosphates will pay. Spanish engineeers maintain that no regular formation will be found unless the workings are carried to a great depth, whilst English engineers say that the work will not be profitable unless good ore is found near the surface. Mr. Pickford, a well-known authority on phosphates, together with Mr. Turnbull, are now visiting the district, but their opinion has not yet been made known. They have already taken on trial some mines at Las Casistas de Belvis in the neighbourhood, and their property amounts to 320 hectares. The property at Navalmoral, which is in the hands of the original concessionaires, is about 550 hectares, and is more favourably situated for transport. M. L'Homme has stated that he can concentrate ores, of however poor quality, so that they will attain a richness of 70 per cent. If this be practicable, the upper deposits could certainly be worked at a profit.

SALE OF THE CACERES PHOSPHATE MINES.—The Caceres mines of the General Caceres Phosphate Company are to be sold by auction on the 11th of May with the land and buildings and the sulphuric acid and superphosphate works. The reserve price of this large property is only £20,000, which shows an evident wish to sell. The ores are said to yield 30 to 40 per cent., and it is estimated that there are still a million tons in the mines. The original shareholders are to lose all the capital. There is a very small market for these phosphates in Spain itself.

NEW RAILWAYS IN THE NORTH OF SPAIN.—Many new schemes are projected for narrow gauge railways in the North of Spain, whilst those in course of construction are being vigorously pushed forward. General confidence in the success of these lines is felt, in consequence of the success of the Durango Railway, the shares of which are quoted at 244. This company pays very high dividends, which will be further increased when the new line from Elgoibar to San Sebastian is finished in 1893. This line would, however, be adversely affected by the construction of the proposed broad gauge line from Bilbao to San Sebastian. Important lines are also being made in Asturias, Leon, Palencia, and Galicia, among which the line from La Robla to Valmaseda, 270 kilometres in length, is worthy of especial notice.

NEW YORK, 4TH APRIL, 1891.

SAW FOR BORING BARRELS.—The Mason Machine Works, Taunton, Mass., have just completed a core saw, for the purpose of boring out barrels from a solid log. The machine is entirely new, and can turn out a barrel complete in one minute. The saw was given a trial in the carpenters' department recently, and worked successfully, boring out a core 10½in. in diameter, and 21½in. long, in 30 seconds. This saw is made of wrought iron, in the shape of a barrel, with steel cutters distributed a certain distance apart about the cylinder, and will bore out all sizes of barrels.

NEW ELECTRIC LAMP.—Mr. J. W. Ellis, of Pittsburgh, has recently brought out a new electric lamp. It is said that the new lamp will burn continually for 500 hours without any attention or care, and without a change of carbons. This prolonged endurance is made possible through the peculiar construction of the carbons, which, instead of pencil-shape, are made in the forms of miniature emery wheels, 4in. and 8in. in diameter, one wheel of each size being used on every lamp. They are placed at right angles, the larger over the smaller one, and by an automatic electrical arrangement enclosed in the lamp they are kept in constant motion.

ELECTRIC WELDING.—The Thomson Electric Welding Company has made arrangements with the Pullman Palace Car Company for an electric welding plant to be located at Pullman, Ill. The plant will be used for miscellaneous car work, embracing the welding of truss rods and similar work on passenger, street, and freight cars.

FLOATING EXHIBITION.—It is reported that a society is in course of formation at Boston for the organisation of a floating Exhibition of North American products. The floating Exhibition will consist of four steamers, three of which will be used for exhibits, and the fourth for the accommodation of the exhibitors or their representatives. It is proposed to make a voyage of from three to six weeks' duration, visiting the West Indies, Central America, and South America.

ELECTRIC TRAMWAYS.—The Thomson-Houston Electric Company has entered into a contract for forty additional cars with the Cincinnati Street Railway Company of Cincinnati, O., and for six cars with the Pueblo City Railway Company, of Pueblo, Col. The company has also entered into contracts with the Creek Rock Railway, Washington, D.C., for twelve cars; Harrisburg City Passenger Railway, Harrisburg, Pa., fourteen cars; City Electric Railway, Little Rock, Ark., for twenty-eight cars; Jefferson Avenue Railway, St. Louis, Mo., twenty-five cars; Oxford Lake Line, Armiston, Ala., six cars; Allentown and Bethlehem Rapid Transit Company, Allentown, Pa., fifteen cars; Marquette City and Presque Isle Company, Marquette, Mich., three cars; Braddock and Turtle Creek Railway, Braddock, Pa., three cars; Salt Lake Rapid Transit Company, Salt Lake City, Utah, three cars; Buffalo Street Railway Company, Buffalo, N.Y., twelve cars; Pittsburgh and Birmingham, Pittsburgh, Pa., two cars; Troy and Alpia Street Railway Company, Troy, N.Y., twenty cars; St. Louis and Suburban Street Railway Company, St. Louis, Mo., forty-five cars; Chattanooga and North Side Railway, Chattanooga, Tenn., four cars.

A NEW LIQUID FUEL BURNER.—A new form of crude oil burner has recently been introduced by the Shipman Engine Manufacturing Company, of Rochester, for which some points of superiority are claimed. Among these may be mentioned simplicity of construction and manipulation, perfect safety, which is ensured by the placing of the oil trap a few inches below the level of the burner, and ease of regulation and cleaning. A specially designed oil cup for use with thick oil can be furnished, which makes it possible to use oil of a density heretofore impossible to use on account of the difficulty of atomising it, but which with this improvement may be thrown in as fine a spray as is desired.

PHILADELPHIA, 3RD APRIL, 1891.

THE COKE INDUSTRY.—The McClure and Frick Companies, who control the greater part of the furnaces in the Connelsville coke region, have issued notices that they desire their men to return to work at a reduction of 7 per cent. The men are assured that wages will not fall lower than $1 per 100 bushels, and are offered a sliding scale, with the understanding that if the price of coke increases to $2·15 they will be paid the old rates. Labour agitators are trying to persuade the men not to accept the offer. Some of the workmen have, however, already done so, in consequence of their distressed condition. There has been much excitement among the men, and some rioting has occurred.

TINPLATE WORKS IN ST. LOUIS.—The St. Louis Stamping Company is erecting tinplate works with a capacity of 500 boxes per day. At present the iron used by this company in the manufacture of tinplate is brought from Chattanooga, Penn., but it is proposed by the company to erect a large steel and iron mill near Madison, Ill. There will be 2,000 men employed.

NEW TRIAL OF THE "BENNINGTON."—The Secretary of the Navy has authorised a second trial of the gunboat "Bennington," which, in its recent trial, failed by 85 horse-power to develop the horse-power (3,400) required by the contract. The contractors, Messrs. N. F. Palmer & Co., having made some alterations, are hopeful of meeting the requirements.

PROGRESS OF THE NEW CRUISERS.—The new cruisers, "Nos. 5 and 6," now being built at Bath, Maine, are progressing rapidly, and it is probable that, if no unforeseen delay occurs, they will be launched in October. Orders have been received at the Portsmouth Navy Yard to commence work on outfits, consisting of spars, blocks, boats, furniture, and cooperage for those cruisers, as also for "Nos. 9 and 10," now being built at Baltimore, and "No. 11," being built at Boston.

RAILROAD SCHEMES.—The purchase of the Pittsburgh and Western Railroad and of the Union Bridge, which runs to Alleghanny and forms a connection with the lines of the former company and the lines from Pittsburgh by the Baltimore and Ohio Railroad Company, is probably the beginning of an enormous project on the part of the Baltimore and Ohio Company. It is stated that it is the intention of this company to construct a line parallel to the Pennsylvania Railroad from Baltimore to Chicago, a distance of over 1,000 miles. The acquisition of these properties will enable the Baltimore and Ohio to construct a direct line between those cities and reduce the distance materially. It is stated that Mr. Andrew Carnegie, of the firm of Messrs. Carnegie, Phipps, & Co., is the real author of this project, and that he intends to withdraw from the active management of his enormous iron interests in order to accept the presidency of the Baltimore Railroad. When the New York Central bought the Rome, Watertown, and Ogdinsburg Railroad, it was thought that the former would make some arrangement with the Canadian Pacific by which the latter company would obtain an entrance into New York. It is now announced that the Canadian Pacific will be permitted to run its trains over the Rome, Watertown, and Ogdinsburg and the West Shore Railroads.

AN IMPROVED SKID FOR HEAVY VEHICLES.

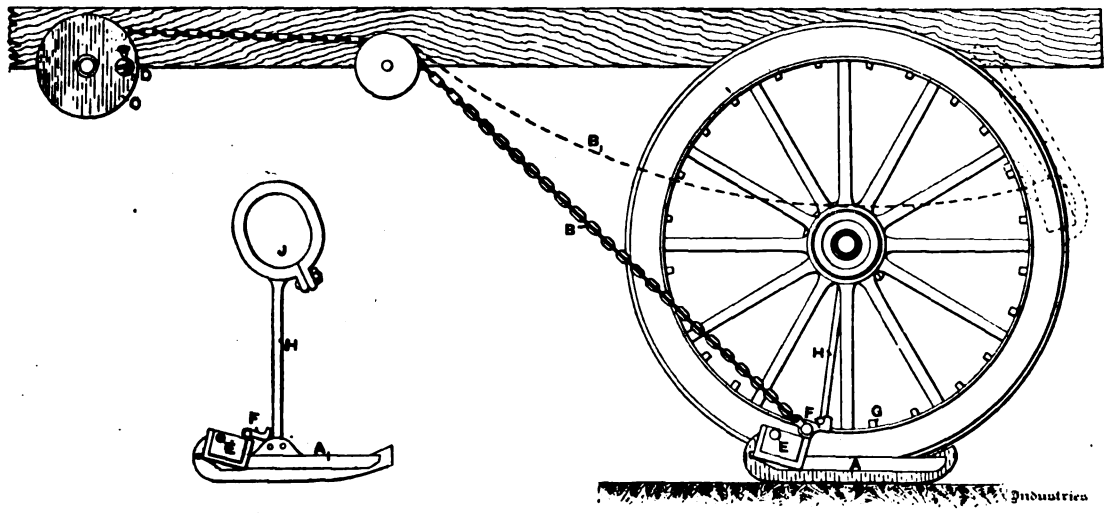

Fig. 1.

Fig. 2.

AN IMPROVED SKID FOR HEAVY VEHICLES.

The ordinary method employed for skidding the wheels of heavy road vehicles, such as lorries, vans, &c., has always been a source of danger to drivers, who frequently have to dismount from their vehicles to operate the skid. The apparatus we are about to describe, and which is shown in the accompanying illustrations (Figs. 1 and 2), is the invention of Mr. John Robertson, of 2, Victoria Street, Newton Stewart, Wigtownshire, N.B., and is intended to obviate the necessity of the driver stopping his vehicle and dismounting to apply the skid. It has, we are informed, been well tested in Scotland, and has given satisfactory results. The skid A, when not in use, is suspended by the chain B in front of the wheel, as shown by the dotted lines. When the wheel is to be skidded, the driver releases a chain wheel C by means of a split hand D, thereby paying out sufficient of the chain to allow the skid to reach the ground and the wheel to mount on the top of it. He then simply lets go the hand, and the chain wheel becomes again locked, and the skid is securely held by the chain. By means of a peculiarly constructed box E on the skid A, the driver is enabled to unskid the wheel without stopping the vehicle or dismounting. To do this he simply pays out a little more of the chain, and allows the wheel to ride off the skid, a claw F on which engages with a pin G on the wheel, thereby carrying the skid up to its normal position, shown in dotted lines. While the latter operation is taking place, the driver again winds up the chain, so that, when A has reached its extreme height, it falls, by its own weight, through a slight angle and tightens the chain, thus releasing the claw F from the pins G. The arm H, which connects the skid with the nave of the wheel, has upon its upper end a collar J (Fig. 1) of an elliptical form for embracing the nave, so that sufficient play is allowed between the skid and the tyre when the former is out of use, but which perfectly fits the wheel when upon the ground.

THE INSTITUTE OF MARINE ENGINEERS.

The annual meeting of this Institute was held on the 3rd inst. In the unavoidable absence of the President, Mr. Wymer, Vice-President, occupied the chair. The Chairman thought the Institute was to be congratulated on the satisfactory state of the finances.

On the subject of a building for the Institute, Captain G. E. Hodgkinson said there must be a special building, and he thought that when it was known that such important work was to be carried on, money would be forthcoming. A great deal might be done by the members, but all who were interested in shipping would see it was to their advantage to enable the marine engineer to attain to a fuller knowledge of his profession. The position of the new Institute must be central for the majority of the members; it must contain club accommodation, reading rooms, library, lecture rooms, and other rooms.

On the invitation of the Chairman, Mr. A. Thomson spoke on the subject of local centres, and said that it would be very important to have centres in large ports, as Liverpool and Glasgow, similar to that being established in Cardiff. A vote of thanks to the Chairman brought the meeting to a close. The ordinary meetings will be held on the second and fourth Tuesdays in April and May, when papers will be read or discussed.

CLYDE SHIPBUILDING FOR MARCH.

The condition of the Clyde shipbuilding industry is not very reassuring, as the demand for new vessels is not brisk enough to replace the removals from the stocks. The output during the month exceeded 41,000 tons, while the aggregate of the contracts booked barely reaches 20,000 tons, and, whereas the total amount of work in hand at this time last year was 230,000 tons, the estimated amount at present under construction is fully 20,000 tons less. Notwithstanding that the current prices of material are much lower than they were a few months ago, there appears to be considerable hesitation on the part of shipowners generally to come to terms with builders. Prices for all classes of vessels seem to have a downward tendency, and as an instance of the low figures at which contracts are at present being paid, it may be stated that a steel barque, to carry 2,100 tons deadweight, has been placed with a well-known firm of builders, the contract price for the same being only £12,500. Among the most important orders booked during the month are three screw steamers, each of 3,500 tons, to be built by Messrs. Caird & Co., Greenock, two being for the Nederland Steamship Company, and the other for the Gulf Line; a steel barque of 2,000 tons, to be built by Messrs. A. McMillan & Sons, Dumbarton, for a Greenock firm; a steamer of 1,850 tons, to be constructed by the Campbeltown Shipbuilding Company, for English owners; and two steamers, one of 1,000 tons and the other of 200 tons, to be built by Messrs. Scott & Co., Greenock, for Brazilian owners.

The majority of vessels launched were of the cargo type, and of small tonnage; two, however, call for special notice, the s.s. "Dunera" and the twin-screw, wood-sheathed, protected cruiser, "Indefatigable." The "Dunera" was launched from the Pointhouse shipbuilding yard of Messrs. A. & J. Inglis, and measures 440ft. in length over all, 48ft. in breadth, and 32ft. in depth. She will be fitted with triple-expansion engines by the builders to develop 5,000 i.h.p., and will have spacious accommodation in the bridge-house amidships for eighty first-class passengers, while second-class passengers to the number of forty will be berthed aft under the poop. Hydraulic gear of the most approved description will be fitted for manipulating the cargo, and she will also be supplied with refrigerating machinery and a complete electric light installation. The "Indefatigable" is the first of three second-class protected cruisers which are at present under construction by the London and Glasgow Engineering and Iron Shipbuilding Company for the British Admiralty. She is intended principally for service in foreign waters; her hull is therefore sheathed with teak and covered with copper to a height of 3ft. above the normal water line. The stem, stern post, and shaft brackets are of phosphor-bronze, and the propellers are of gun-metal. Her dimensions are as follow:—Length, 300ft.; extreme breath, 43 66ft.; depth, moulded, 22·75ft.; and displacement, 3,600 tons. She will be fitted with two sets of inverted triple-expansion engines capable of developing collectively 9,000 i.h.p., the diameters of the cylinders being 33·5in., 49in., and 74in. respectively, with a stroke of 39in., and with which it is expected that a speed of 20 knots will be realised. Steam will be supplied from five steel boilers, working at a pressure of 155lb. per square inch. The armament will consist of two 6in. breech-loading guns mounted on central-pivot carriages, one on the poop and the other on the forecastle, six 4·7in. quick-firing guns, eight 6-pounder Hotchkiss guns, four 5-barrelled Nordenfeldt guns, and four torpedo tubes.

The following are the particulars of vessels launched during the month:—

Screw Steamers.

"Acanthus," steel, 3,000 tons, built and fitted with triple-expansion engines by Messrs. Alexander Stephen & Sons, Linthouse, for Mr. John Bruce Murray, Glasgow.

"Ardgowan," steel, 230 tons, built and engined by James M'Arthur & Co., Paisley, for Messrs. Hendry & Steele, Glasgow.

"Bohemia," steel, 3,000 tons, 2,000 i.h.p., built and fitted with triple-expansion engines by Messrs. D. and W. Henderson & Co., Partick, for the Anchor Line fleet of Messrs. Henderson Bros., Glasgow.

"Cynthiana," steel, 3,000 tons, built by Messrs. Russell & Co., Greenock, and fitted with triple-expansion engines by Messrs. Blackwood & Gordon, Port Glasgow, for the general trade of Messrs. M'Lean & Sutherland, Glasgow.

"Dunera," steel, 5,600 tons, built and engined by Messrs. A. & J. Inglis, Pointhouse, for the Australian trade of the British India Association.

"Genkai Maru," steel, 1,380 tons, built by Messrs. Napier, Shanks, & Bell, Yoker, and fitted with triple-expansion engines by Messrs. J. & J. Thomson, Finneston, for the Japan Mail Steamship Company.

"Gulf of Genoa," steel, 3,300 tons, 2,000 i.h.p., built and fitted with triple-expansion engines by Messrs. Caird & Co., Greenock, for the Greenock Steamship Company.

"Hibernia," iron, 149 tons, 320 i.h.p., built and engined by Messrs. Mackie & Thomson, Govan, for Mr. Henry Bennett, Grimsby, for the North Sea fishing trade.

Hopper Barge, steel, 300 tons, 250 i.h.p., built and engined by Messrs. Wm. Simons & Co., Renfrew, for the Preston Corporation.

"Loo Sok," steel, 1,650 tons, built and fitted with triple-expansion engines by the Fairfield Shipbuilding Company, Govan, for the Scottish Oriental Steamship Company, for service on the China coast.

"Marie," iron, 191 tons, built by Messrs. Scott & Co., Bowling, and fitted with compound surface condensing engines by Messrs. Muir & Houston, Glasgow, for the fish trade of Messrs. M'Kinney & Rafferty, Glasgow.

"Red Rose," iron, 400 tons, built by Messrs. John Fullerton & Co., Paisley, and engined by Messrs. Hutson & Corbett, Glasgow, for the coasting trade of Messrs. R. Hughes & Co., Liverpool.

"Scotia," steam trawler, sister ship to the "Hibernia," by the same builders, for the same owners.

"Satung," steel, 2,500 tons, built and engined by Messrs. Scott & Co., Greenock, for the China Navigation Company.

Barges.

Messrs. Fleming & Ferguson, Paisley, shipped to China two barges, each of 400 tons and 500 i.h.p.

War Ships.

"Indefatigable," steel, wood-sheathed, 3,600 tons, 9,000 i.h.p., built and engined by the London and Glasgow Engineering and Iron Shipbuilding Company, Govan, for the British Government.

"Ab-bāss," 800 tons, despatch cruiser, built by the Ailsa Shipbuilding Company, Troon, to the order of the Egyptian Government, for service in the Red Sea.

Sailing Vessels.

"Ancoria," steel, 1,800 tons, built by Messrs. Russell & Co., Greenock.

"Bardowa," steel, 2,070 tons, built by Messrs. William Hamilton & Co., Port Glasgow, for Messrs. Harvie, Hamilton, & Co., Glasgow.

"John Carswell," steel, 1,400 tons, built by Messrs. Chas. Connell & Co., Whiteinch, for Mr. John Carswell, Greenock.

"Josephine Troop," steel, 1,580 tons, built by Messrs. Robert Duncan & Co., Port Glasgow, for Messrs. Troop & Son, St. John, New Brunswick.

"King Edward," steel, 1,700 tons, built by Messrs. Russell & Co., Port Glasgow, for Messrs. J. A. Walker & Co., Glasgow.

"Tolus," steel, 2,000 tons, built by Messrs. Barclay, Curle, & Co., Whiteinch, to the order of Messrs. A. & F. H. Carmichael, Greenock.

In addition to the above the Abercorn Shipbuilding Company, Paisley, shipped abroad three barges, each of 95 tons, and two barges, each of 50 tons.

Yachts.

"May," steel," steam yacht, about 500 tons, 242ft. long, built by the Ailsa Shipbuilding Company, Troon, to the order of Mr. N. B. Stewart, Wemyss Bay.

Steam Launch, 10 tons, 42ft. long, built by Mr. R. Rodger, Greenock, for service in the West Indies.

SHIPBUILDING NOTES.

ON the 3rd inst. the "Oscar," a steel screw steamer, which has been built by Sir Raylton Dixon & Company, to the order of Messrs. Potter Bros., of London, for Messrs. Giovanni G. Gargurerich & Co., of Trieste, proceeded from the Tees to the Tyne on her trial trip. This vessel is built on the web-frame principle, with raised quarter-deck, bridge, and forecastle, and is of the following dimensions:—Length, over all, 243ft. 9in.; breadth, 34ft. 6in.; depth, moulded, 17ft. 1in. The engines have been supplied by the North-Eastern Marine Engineering Company, Limited, Sunderland, and have cylinders 19in., 30in., and 49in., by 33in. stroke.

ON the 7th inst. the "Mira," a screw steamer of 1,000 tons, was launched by Messrs. A. & J. Inglis, Pointhouse. The vessel has been built to the order of "Det Bergenske Dampskibsselskab," Bergen. The dimensions are:—Length, 204ft.; breadth, 30ft.; depth, 23ft. 9in. Her engines are triple-expansion, with cylinders 20in., 32in., and 52in. in diameter respectively.

ON the 9th inst. Messrs. Sir Raylton Dixon & Co. launched from their No. 2 Dockyard, Middlesbrough, the steel screw steamer "Endsleigh," which has been built to the order of Messrs. Bellamy & Co., of Plymouth. Her leading dimensions are:—Length, over all, 290ft. 3in.; breadth, 39ft.; depth, moulded, 21ft. 11in., with a deadweight capacity of about 3,500 tons. Her engines will be fitted by Messrs. Blair & Co., Limited, of Stockton, having cylinders 21in., 35in., and 57in., by 39in. stroke.

ON the 9th inst. a large screw steamer, the "Croft," was launched from the building yard of the Blyth Shipbuilding Company, Limited, at Blyth. This vessel has been built to the order of Messrs. Dent & Co., of Newcastle and Blyth, and will be a valuable addition to their well-known Arrow Line of steamers. The dimensions of the vessel are as follow:—Length, 312ft.; breadth, 40ft.; and she is built of steel, with web frames and cellular double bottom for water ballast throughout. The engines for this vessel are triple expansion, and are being made by Mr. J. Dickinson, of Sunderland.

ON the 9th inst. Messrs. Craig, Taylor, & Co. launched from their Thornaby shipbuilding yard, Stockton-on-Tees, the steel screw steamer "Highland Mary," of the following dimensions:—323ft. by 41ft. by 28ft. 7in. The vessel is built for the dead meat trade, and it is intended to carry 100,000 carcases. The holds are insulated, and the vessel will be fitted with refrigerating apparatus by Messrs. J. & E. Hall, Limited, of Dartford, Kent. The engines, on the triple-expansion three-crank principle, are by Messrs. Westgarth, English, & Co., Middlesbrough, and the diameters of the cylinders are 23½in., 37½in., and 60in., by 42in. stroke. The vessel has been built to the order of Messrs. Hugh Nelson & Co., of Liverpool.

ON the 10th inst. Messrs. Wm. Simons & Co. launched complete from their yard at Renfrew the second of three steam hopper barges for the Corporation of Preston. The dimensions of the vessel are as follow:—Length, 130ft.; breadth, 24ft.; depth, 9½ft.; and it has a hopper capacity to contain 300 tons of dredgings. The engines will indicate 250 h.p. The first of these vessels, which was launched last month, is now at work at Preston.

ON the 10th inst. Messrs. Edward Withy & Co. launched from their yard at Hartlepool a large steel screw steamer, "Castle Ventry," built to the order of Messrs. Sivewright, Bacon, & Co., West Hartlepool. The vessel measures over 320ft. in length, and is built throughout of Siemens-Martin steel, with a large deadweight capacity, and is built to the highest class at Lloyd's. The vessel has a long raised quarter-deck, long bridge-house, and a top-gallant forecastle. The holds are fitted with iron grain divisions, and all decks, deck erections, skylights, bulwarks, bulkheads, &c., are constructed of steel and iron. A cellular bottom is fitted fore and aft for water ballast. The greater portion of the plates are in 24ft. lengths, making the structure of the ship very strong. She will be fitted with triple-expansion engines by Messrs. T. Richardson & Sons, Hartlepool.

ON the 11th inst. Messrs. Schlesinger, Davis, & Co. launched from their shipyard at Wallsend a new vessel which they have built for the Tyne Steam Shipping Company, Newcastle. The vessel is intended for the trade between Newcastle and London. The following are the dimensions of the vessel:—Length, over all, 280ft.; length between perpendiculars, 270ft.; breadth, moulded, 35ft.; depth, moulded, 18ft.; depth of hold, 17ft. The vessel has been constructed to class 100 A1 at Lloyd's. The vessel will be lighted throughout by the electic light, to be supplied and fitted by Messrs. J. H. Holmes & Co., of Newcastle. The engines, which are placed in the after part of the vessel, have been constructed by the North-Eastern Marine Engineering Company, Limited, at their Wallsend works, and are designed to indicate 2,700 horse-power. They are on the triple-expansion three-crank type, having cylinders 30½in., 48½in., and 77½in diameter, and a stroke of 48in. Steam is supplied from four large boilers arranged so that the firing can be done in one stokehold.

Notices of Meetings.

THIS WEEK.

ROYAL INSTITUTION.—Friday, April 17th, at 9 p.m. Lecture on "Magnetic Rocks," by Professor A. W. Rücker, F.R.S. Saturday, April 18th, at 3 p.m. Lecture II., on "The Dynamo," by Professor S. P. Thompson.

PHYSICAL SOCIETY.—Friday, April 17th. Papers to be read: "On a Property of Magnetic Shunts," by Professor S. P. Thompson; "An Alternating Current Influence Machine," by Mr. J. Wimshurst.

JUNIOR ENGINEERING SOCIETY.—Friday, April 17th, at 8 p.m. Papers to be read: "On a Pitchometer," by Mr. W. H. De Ritter; "Concrete and its Uses," by Mr. F. R. Taylor.

NEXT WEEK.

SOCIETY OF CHEMICAL INDUSTRY.—Monday, April 20th, at 8 p.m. Papers to be read: "Stoneware and its Application to Chemical Apparatus," by Mr. W. P. Rix; "Tanning by Electricity," by Dr. S. Rideal and Mr. A. P. Trotter.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.—Monday, April 20th, at 8 p.m. Sessional meeting.

INSTITUTION OF CIVIL ENGINEERS.—Tuesday, April 21st, at 8 p.m. Paper to be further discussed: "The Cost of the Generation and Distribution of Electrical Energy," by Mr. R. E. B. Crompton, M.Inst.C.E.

ROYAL INSTITUTION.—Tuesday, April 21st, at 3 p.m. Lecture on "The Geography of Africa," by Mr. J. Scott Keltie. Thursday, April 23rd, at 3 p.m. Lecture on "Recent Spectroscopic Investigations," by Professor Dewar, F.R.S.

SOCIETY OF ARTS.—Tuesday, April 21st, at 4.30 p.m. Lecture on "China," by Sir Thomas Wade, G.C.M.G., K.C.B. Wednesday, April 22nd, at 8 p.m. Lecture on "Bimetallism," by Sir Guilford Molesworth, K.C.I.E.

PRICES CURRENT, 15TH APRIL, 1891.

Quotations at per ton, unless otherwise specified.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER: There is no change of importance to report in the position of the copper market. The amount of business taking place is unimportant, and values are a shade weaker. Chili bars have receded about 10s. during the past week, to-day's quotations being £51 17s. 6d. to £52 5s. cash, with quiet market. Manufactured steady at £65, "strong," with a possible concession for good orders.

TIN: Quiet, with a tendency to lower values. Prices of foreign are down 10s. during the week.

LEAD: Steady; prices unchanged.

SPELTER: A little lower, owing to extreme depression in the galvanising trade.

MESSRS. LAING, WHARTON, & DOWN have sent us an illustrated catalogue of their electric light machinery. It includes almost everything needed for electric light installations, and contains a number of line illustrations of designs of a very large assortment of artistic fittings.

Digitized by Google

HOME INDUSTRIES.

LONDON, 16th April, 1891.

The Money Market.—The withdrawal of substantial sums in gold from the Bank of England for Russia has upset the money market, and the shadow of an advanced Bank rate hung over Lombard Street since the end of last week. Discount business has been restricted by the hardening of rates, but loan money has remained plentiful and fairly cheap. In the stock market the week began promisingly, and prices advanced in nearly every department. The improvement did not last long, and a reaction quite as marked as the upward movement occurred. American railroad securities had led the market up, and a set-back in them, induced by the failure of a conference of railroad officials at Chicago, on which great hopes had been based, depressed other securities. Grand Trunk stocks, which, in sympathy with Americans and Canadian Pacifics, had been strong for several days, gave way in consequence of the cold reception of Sir Henry Tyler at the half-yearly meeting and the shareholders' refusal to re-elect the retiring directors. In home railways no feature has developed, and, but for a little activity in the stocks of the lines most affected by Sir Edward Watkin's new London project, and for an advance in the Scottish stocks, due to the closing of "bear" accounts, there has been little to record. Foreign securities have been very quiet, South Americans showing fresh disposition towards weakness. Shares in industrial companies have been inactive, and mining shares have been rather neglected.

Institution of Mechanical Engineers.—The ensuing ordinary general meeting of this Institution will be held on the 30th inst. and the 1st of May, at 7.30 p.m., under the presidency of Mr. Joseph Tomlinson. The following papers will be read and discussed:—"Research Committee on Marine Engine Trials: Report upon Trial of the Steamer 'Iona,'" by Professor A. B. W. Kennedy, F.R.S.; "On Some Details in the Construction of Modern Lancashire Boilers," by Mr. Samuel Boswell. The anniversary dinner is announced to take place on the evening of the 29th inst.

The Junior Engineering Society.—On the 6th inst. a large party of members of this Society visited the electrical engineering works of Messrs. Siemens Brothers & Co., at Charlton. The visitors were shown round in small parties, an arrangement which greatly enhanced the success of the visit. The instrument section proved very interesting, as did also the contents of the show room, which included keys, relays, switches, Morse instruments arranged for simplex, duplex, and translation work, Wheatstone automatic instruments capable of sending 400 words per minute, galvanometers, resistance coils, block signalling apparatus, and special automatic block systems for electrical railways. The process of manufacture of indiarubber core was seen, and also the wire-testing shop, cable machine shop, cable tanks, and cable-testing room. Here a special bridge for very low resistances was shown; its range was from 1 ohm to 1 millionth of an ohm. The manufacture of lead-sheathed core by means of powerful hydraulic machinery was in progress, and in the large machine shop the heavy parts of dynamos were being prepared. The mode of erection of an iron telegraph pole and the general arrangements of telegraph work were explained.

Electric Traction at Greenwich.—Some successful experiments have recently been carried out at Messrs. Merryweather & Sons' Tramway Works, Greenwich, on behalf of the Gordon Electric Car Syndicate, and have given excellent preliminary results. The track has closed conduits, and the general idea of the system is a series of contacts changed by means of automatic magnets in a box placed in the ground every hundred yards or so, about sixteen to a mile. The working pressure is 250 volts and the current 30 amperes. The current taken in energising the magnets is ¼ ampere, and the greatest loss in running across the sections is about 1 ampere—that is, in all, including resistance, say, 4 per cent. of that used. Any gearing or motor can be used—at present an Immisch motor is employed, with ordinary spur gearing. It is expected that the system will shortly be applied to a complete tramway line, in order to verify under ordinary conditions of street traction the satisfactory results shown by the experiments. Messrs. Merryweather & Sons have sent us a copy of their new circular referring to the patent Sphincter grip armoured hoses, and the non-kinkable red grey hoses, &c., of which the firm make a specialty.

Exhibition of Artistic Silken Fabrics.—The second Exhibition of artistic silken and other fabrics of British manufacture will be held at the Æsthetic Gallery, 155, New Bond Street, early in May. The object of these Exhibitions is to further the efforts of the Ladies' Committee of the National Silk Association on behalf of home manufactures by establishing a central depôt in the West End of London for the distribution of artistic British textile fabrics. Further particulars will be shortly announced.

Business Announcement.—Messrs. Woodhouse & Rawson United, Limited, have opened new show rooms at 34, Cannon Street, at the corner of Queen Victoria Street. In view of the large number of orders for steam and electric launches and tugs the company have resolved to extend their riverside premises, and have, therefore, just purchased a piece of ground, situated close to Kew Railway Bridge on the Surrey side, with a frontage to the river of between 600ft. and 700ft., the total area being about 2½ acres. Good dock accommodation will be provided in connection with these works.

MANCHESTER, 16th April, 1891.

Manchester Association of Engineers.—On the 11th inst. Mr. C. F. Budenberg, B.Sc., read a very interesting paper before the Association on "Steam Engine Governors." After dealing exhaustively with the well-known Watt, Buss, Porter, and Proell types, the author described the "four-pendulum" governor, the Lüde and Soho governors, and a simple expansion gear made by Messrs. Cochrane, Grove, & Co., Middlesbrough. We hope, in a later issue, to reproduce this paper in full.—On the 13th inst. about 130 members of the Association paid a visit of inspection to the recently erected locomotive works of the Lancashire and Yorkshire Railway Company at Horwich. They were conducted through the extensive works, and were enabled to see most of the shops. Among the special objects of interest an ingenious application to a drilling machine may be mentioned, by which a single-spindled radial drilling machine is enabled to drill three holes simultaneously. The centre drill is fitted in the chuck of the drill spindle, on which is fixed a spur wheel, which engages with two similar wheels fastened on two chucks which are borne in a square frame carried on the drill spindle. In this way three drills are easily employed, and the drilling of fire-box plates and similar work is thus more easily accomplished. In the signal department a special combined milling and drilling machine, made by Messrs. Wm. Muir & Co., is noticeable. The machine is employed to mill the faces of quadrant brackets on which there are six faces, all of which are milled at one operation, the two wings being hinged and brought up to their work when required. The drilling head is at the back of the machine, and has three spindles, which are easily brought into operation when necessary. The steel foundry is now in full operation, and some creditable specimens of wheel centres and motion work are being turned out. The shops are a fine range, and their orderly arrangement were much remarked upon. A vote of thanks to Mr. J. A. F. Aspinall was cordially passed at the conclusion of the visit.

Technical Education in Cheshire.—The Technical Instruction Committee of the Cheshire County Council have decided to recommend to the Council the granting of several sums to various institutions in the county for increasing the provision for instruction in agriculture and dairy practice. In addition to this a certain proportion of the sum at the disposal of the Council is to be granted to such urban authorities as decide to place themselves under the recent Act. The Cheshire Chamber of Agriculture proposes that the County Council should rent and equip a farm on which instruction in practical and theoretical agriculture can be given. The cost for rent and salaries is estimated at about £1,000, and that of fixed stock and implements at from £1,000 to £2,000. It is suggested that three-fourths of the cost should be subscribed by the Council and the remainder by private subscriptions.

Cotton Machinery.—Messrs. John Hetherington & Sons, Limited, have received the order for the whole of the machinery required for the Milton Spinning Company, Limited, Mossley, consisting of 80,000 spindles and the usual preparation machinery. This is the sixth mill during the past half year for which the order for the machinery has been secured by this firm.

Business Announcement.—Mr. David Fulton, F.I.P.A., Assoc.Mem.Inst.C.E., of 1, St. James Square, and of the Middle Temple, was successful at the Easter Final Examination for call to the Bar. Mr. Fulton has during the last six years practised as a consulting engineer and patent agent at Manchester, in partnership with Mr. E. K. Dutton.

The Fifty-three Hours Question.—Although a specially convened meeting of the Iron Trade Employers' Association has decided that its members should not accede to the demand for the shortening of the weekly hours to 53, the question is not likely to give rise to any prolonged dispute. The state of trade is such that many firms are quite prepared to yield, and are, it is stated, preparing for the change. Careful inquiry shows that there is a widespread conviction that the demand will be granted, and that even a partial strike is unlikely.

The Arts and Crafts Exhibition.—The attendance at this Exhibition since it opened has exceeded expectation In three weeks 74,926 visitors have passed the turnstiles, and 6,259 catalogues have been sold. Although the collection might be amended, it is in many respects one of the most notable ever got together in this city, and a large number of artisans have visited the Exhibition. There are many specimens of iron work of considerable merit, and a case of silk embroidery from the Macclesfield School is also worth special attention.

The Linen and Jute Trades.—There has been a steady business this week, and a striking development in the fancy linen branches. Firms engaged in this department state that the industry is growing every year, Bavarian houses benefiting chiefly from the circumstance. Fancy linen damasks are now largely bought, and the designs shown are remarkable for their originality and style. There is little change in the general linen trade. Distributors are steadily employed, and manufacturers are receiving a few occasional orders. The demand, however, is not equal to expectations, and merchants are anxiously looking towards the future. For shipment there is not much doing. South American trade still continues dull, and shippers do not anticipate a change for the better just yet. Linen threads, for which there is always a good demand, are being freely taken off the market. The wholesale clothiers of this district are extensive buyers. Jute goods, especially in fancies, are in good request.

GLASGOW, 16th April, 1891.

The Iron and Coal Markets.—On the reopening of the market on the 14th inst., after the spring holiday, there was an increase in the demand. Prices advanced rapidly, and, "bears" beginning to cover their transactions, the advance was maintained for a time. There has been a better feeling in mineral circles during the past few days. Several large mineral contracts are on the point of being made, including one of 40,000 tons of coal for the Danish State Railways, and generally the foreign demand is rather brisker. The uncertain issue of the present labour agitations on the Continent is helping to stimulate forward contracts for Scotch coal, especially for German consumption. Pig iron shipments, however, for last week showed a large decrease. The foreign shipments were only 2,886, against 5,565 tons for the corresponding week last year; coastwise shipments were 2,980 tons, against 4,221 tons last year. The decrease of pig iron shipments up to date this year is 55,571 tons. Coal shipments last week increased 17,574 tons, the decrease for the year being now reduced to 53,108 tons.

The Railway Schemes.—The Committee of the Edinburgh Town Council, which is carrying on negotiations with the North British Railway Company with respect to their proposal to acquire a portion of Princes Street Gardens for the purpose of enlarging the Waverley Station at Edinburgh, held a conference with the directors, manager, and secretary of the company in Edinburgh on the 14th inst. The conference was held in private, but it is understood that some terms of agreement were arrived at.—The Brechin and Forfar Railway, which, though not promoted by the Caledonian Railway, is ostensibly projected for the purpose of reducing the distance between Perth and Aberdeen by about six miles, is opposed on the ground that the interests of Forfar would suffer through the town being left off the main line.

Threatened Wages Dispute.—The Steel Company of Scotland some time ago gave notice of a reduction of 5 per cent. in the wages of their men. This reduction was generally accepted, but the men in charge of the gas producers have announced their desire to resist the reduction. The company has stated that unless the men submit there will be a general lock-out at the works at Newton and Blochairn. It is to be hoped that an amicable arrangement may be arrived at.

Launch of an Orient Liner.—The "Ophir," a steel twin-screw steamer of 6,700 tons, built for the Orient Steam Navigation Company by Messrs. Robert Napier & Sons, Govan, was launched on the 11th inst. The dimensions of the new vessel are:—Length, 482ft.; breadth, 53ft.; depth, 37ft. The "Ophir" will be employed in the Royal Mail service between London and Australia. The vessel has been built to class 100 A1 at Lloyd's, and is one of the handsomest vessels of the fleet, to which it forms an important addition. There are two sets of triple-expansion engines. The steam is supplied by seven steel boilers with a working pressure of 160lb. to the square inch. The speed is expected to be fully 18 knots. The hull is subdivided by water-tight bulkheads and there is a cellular double bottom. The dining saloon is placed on the upper deck between the funnels, where vibration is at a minimum. There is a promenade deck, unusually ample owing to the great breadth of the vessel. Among the accessories are mechanical ventilation, hydraulic cargo and steering gears, refrigerating apparatus both for stores and for dead meat traffic. The vessel will be fitted throughout with electric light.

The Raising of the s.s. "Utopia."—The Anchor Line steamer "Utopia," which was sunk in Gibraltar Bay, is to be raised. The work has been entrusted to the British Marine Salvage Company, Limited, Glasgow, in conjunction with the East Coast Salvage Company, Limited, Leith. The operations will be superintended by Captain Meikleroid, the marine superintendent of the Anchor Line.

(From our own Correspondents.)

LIVERPOOL, 15th April, 1891.

The Furniture Wood Trade.—There is a good demand for all classes of mahogany, and the market continues firm. There is a good opening for Honduras, the market being poorly supplied. Sound straight logs of Tabasco are in good request, and, as the stock consists of only 125 logs, the prospects for future imports are good. Cargoes from Minatitlan and Cuba will meet with a ready sale at good prices, the inquiries having been large. Logs of St. Domingo of large and medium dimensions are in good request, but small curls under 3ft. long are not required; curls up to 5ft., of good growth, are in demand. There has been a large arrival of African mahogany, which has met with a ready sale at satisfactory prices. There is no stock of pencil cedar, but there is little or no demand. The stock of American walnut is light, although it has arrived very freely; the market has a downward tendency. There are no inquiries for Italian and Circassian, and prices are low. There is a fair demand for logs and planks of whitewood of good quality, and the prices do not fluctuate. There is no stock of Rio and Bahia rosewood, and a small parcel of Honduras has arrived. There has been no business in satinwood, and prices are falling.

The Vyrnwy Pipe Line.—Very little progress has been made with the tunnel under the Mersey at Fidler's Ferry, the contractors having met with serious difficulties in driving the heading. Much difficulty has also arisen in

Digitized by Google

connection with the temporary pipe line which it is proposed to lay across the bed of the river to serve as an auxiliary supply during the construction of the tunnel. It was necessary to obtain the consent of several authorities interested in the navigation of the Mersey before the pipe could be laid. The Corporation of Warrington have raised strong objections to the proposed plan, and have appealed to the Board of Trade to prevent the pipe being laid as proposed. They contend that, as the bed of the river changes its depth so often and so suddenly, if the pipes are not laid well below low-water line they may be washed clear of the bed of the river, and, if not broken by their own weight, they will, at any rate, seriously interfere with the navigation of the river. They wish to have the pipe laid from bank to bank, 7ft. below low-water level.

Liverpool Engineering Society.—At the last meeting of this Society, held at the Royal Institution on the 8th inst., Mr. Alexander Ross, M.Inst.C.E., chief engineer of the Manchester, Sheffield, and Lincolnshire Railway Company, read a paper on "Railway Signalling and Interlocking." The subject was exhaustively treated, the principal systems adopted from the earliest railway times to the present day being fully described and illustrated by wall diagrams.

NORTH STAFFORDSHIRE, 15th April, 1891.

The Iron Trade.—There are no signs of any change for the better in this industry. The quarterly meeting at Birmingham, on the 11th inst., was poorly attended, and there was little buying. Steps are being taken to obtain a reduction in the wages of blast furnacemen. The price of forge pig iron is now from 42s. 6d. to 45s. at works, according to quality, which leaves no margin of profit for manufacturers; on the other hand, blast furnacemen's wages are from 40 to 50 per cent. above the minimum, the last advance having been granted when pig iron was selling at 60s. per ton.

The Coal Trade.—The demand for coal for household purposes continues good. The consumption of fuel for manufacturing purposes is, however, limited, and prices begin to show a weaker tendency.

The Electric Lighting of Trains.—Messrs. Bumsted & Chandler, of Hednesford, have recently supplied a Chandler compound engine and dynamo to the Cape Railways for the electric lighting of the trains on those lines. This is the third set of engine and dynamos supplied to the Cape Railways, two sets having been at work for more than a year. The entire weight of engine, dynamo, and fittings, lamps, &c., for a train of fourteen coaches, having one hundred lights, does not exceed 14 cwt., and the steam consumption is not more than that required for a 6 horse-power engine.

DERBY, 15th April, 1891.

Railway Schemes.—It was stated, at a meeting held at Newark in support of the proposed Lancashire, Derbyshire, and East Coast Railway, that only about 1 per cent. of Derbyshire coal found its way for shipment, whereas 30 per cent. of the Yorkshire coal did so. The new line would stimulate the industry of coal getting, and develop many large manufactures. The proposed line could be constructed at an estimated cost of only £26,000 per mile. The Corporation of Lincoln are opposing the Bill. The inhabitants of Chapeltown have presented a memorial requesting the directors of the Midland Railway to reconsider their intention of constructing heavy stone bridges and an unsightly embankment on the new line from Wincobank. Instead of these structures, they urge that bridges of a light and graceful character should be adopted, whilst for the embankment they would substitute girder bridges, presumably something like those of the New York elevated railroads. Mr. G. H. Turner, the goods manager of the Midland Railway, has been appointed assistant general manager to help Mr. Noble in the increasing duties caused by recent railway legislation.

Electric Lighting.—Mr. Alderman Hobson has announced at a public meeting that the scheme for lighting the town by electricity, which Sir Frederick Bramwell has prepared after his recent visit to Derby, will shortly be laid before the Council, and Mr. Hobson has no doubt it will be adopted at least for the central part of the town.

CARDIFF, 15th April, 1891.

Coal and Coke.—The steam coal trade shows no further signs of weakness, and prices are well maintained. It is, however, necessary that the demand should continue large, as the output from new collieries is steadily increasing, and with the sinking operations now being carried on is likely to expand further. Steam coal is quoted as follows:—First quality, 14s. 3d. to 14s. 9d. f.o.b.; second quality, 13s. 3d. to 14s. f.o.b.; third quality, 12s. 9d. to 13s. f.o.b.; fourth quality, 12s. 3d. to 12s. 6d. f.o.b.; small steam, 5s. 3d. to 5s. 9d. In the house coal market there is little activity compared with the recent demand: best house coal realises 14s. 6d. to 15s.; No. 2 qualities, 12s. 6d. to 13s. 6d. There is only a quiet tone noticeable in the coke trade: furnace qualities are quoted at 17s. 6d. to 19s.; foundry, 20s. 6d. to 21s. 6d.; best foundry, 23s. to 25s.

Iron and Steel.—The result of the quarterly meetings has not been favourable to the manufactured iron and steel trades. The gloomy outlook in the tinplate trade affects the steel trade. Steel tinplate bars have been quoted by makers at £5 2s. 6d. For steel rails one or two contracts have been given out at £4 12s. 6d. to £4 15s. per ton for heavy sections, which is a drop of £3 in little more than twelve months. Tinplates realise 17s. to 17s. 6d. for Bessemer steel cokes. In the iron ore trade good Rubio realises 13s. 6d. to 14s. c.i.f. Cardiff and Newport, with 50 per cent. iron. The freight from Bilbao is 4s. 9d. as against 4s. 3d. a week ago.

Severn Navigation Scheme.—A deputation, comprising members of the Severn Commission, the Worcester Town Council, and Cardiff merchants, waited upon the Corporation on the 13th inst. with the view of inducing the Corporation to confirm the advance of £5,000 to the Severn Navigation Scheme. The Corporation agreed to confirm the advance of the money. The improvements will be at once commenced, and vessels of 400 tons burthen will thus be enabled to trade up the Severn with timber, iron ore, grain, and other imported produce, and to bring back manufactured iron and hardware goods.

BARROW-IN-FURNESS, 15th April, 1891.

Hematite.—Further depression is shown in the hematite pig iron trade this week by the marked absence of new business. There is no change to note in values, which are quoted at 47s. 6d. for warrant iron net cash, while makers are asking 49s. to 50s. for mixed Bessemer numbers f.o.b. Makers are proposing to blow out additional furnaces with the view of diminishing stocks, so as to be able to take advantage of improved trade when it arises. Stocks this week have been reduced 3,823 tons, leaving the aggregate of stocks 175,066 tons. Forty furnaces are in blast and thirty-six are standing idle.

Steel.—The steel trade is quiet, and there are few orders either for Bessemer or Siemens-Martin qualities. Rails are in fair request for heavy sections, but lighter rails are quiet. Heavy sections are still quoted at £4 12s. 6d. per ton net. Steel shipbuilding material is quiet, but good orders are expected from home as well as from general sources. Ship plates are quoted at £6 5s., angles at £6, and steel boiler plates at £6 15s. Orders are scarce for blooms, billets, slabs, and tinplate wire. Extensions are contemplated in the Siemens-Martin department of local steel works, and in the manufacture of steel wire, for which purpose it is intended to acquire large works which have been standing idle in the vicinity of the Barrow Steel Works.

Iron Ore.—Business in the iron ore trade is quiet, and metal is being stored at many mines, with little prospect of a speedy clearance. Prices are steady at 10s. to 10s. 6d. per ton. Some pits are closed temporarily.

A New Industry.—A new feature in the development of the bulk import petroleum trade of Barrow is the commencement of new oil and grease works at Barrow, under the auspices of Messrs. Goodall & Co. Already a large cargo of natural crude mineral oil has been imported, and new developments of this industry are expected.

Shipping.—There is a slight improvement in shipping this week, but the aggregate of metal shipments this year is 32,000 tons less than last year.

MIDDLESBROUGH, 15th April, 1891.

Pig Iron.—The iron market is somewhat more favourable in tone, and prices of pig iron have risen. More business was done on 'Change yesterday than has been done for some time past, though it was small at the best. The advance in Scotch warrants of 1s. 3d. per ton since the 9th inst. has had a good influence on buyers, though it has not much affected the price of Middlesbrough warrants. On 'Change yesterday makers and merchants were willing to take 38s. 3d. per ton for prompt f.o.b. deliveries of No. 3 G.M.B., and were able to get it, though as a rule buyers only offered 38s. Afterwards 38s. 6d. per ton was generally quoted, and buyers raised their offers to 38s. 3d. Some business was reported as having been done at 38s. 6d. by makers. Middlesbrough warrants are 38s. 3d. cash buyers and 38s. 6d. cash sellers. The stock in Connall's store was 119,954 tons on the 13th inst., a decrease of 2,740 tons this month up to date. Grey forge is now quoted at 37s. 3d., and some firms will not sell under 37s. 6d. East Coast hematite is 51s. per ton for mixed numbers.

Manufactured Iron and Steel.—The finished iron and steel industries are very quiet. Nevertheless quotations are fairly well maintained, because it is recognised that a reduction of prices would not lead to an increase of business at present. Common bars are quoted at £5 12s. 6d.; best bars, £6 2s. 6d.; best best bars, £7 2s. 6d.; iron ship plates, £5 12s. 6d.; iron boiler plates, £6 12s. 6d.; steel ship plates, £6 2s. 6d.; iron angles, £5 10s.; steel angles, £5 17s. 6d., all less 2½ per cent. f.o.b. Heavy steel rails are £4 12s. 6d. net.

Coke.—The price of blast furnace coke is the same as last week, 13s. 6d. per ton.

Shipments.—Shipments are improving, and were 28,602 tons up to the 13th inst., as against 30,005 tons to the 13th of last month. They promise to be large for the rest of the month. Of the 28,602 tons, 16,755 tons went to Scotland, 2,280 tons to England and Wales, and 9,567 tons to foreign parts.

Work and Wages.—The South Stockton Iron Works have recommenced operations this week, the directors having secured some specifications at remunerative prices. The representatives of the Cleveland ironstone miners met the members of the Cleveland Mineowners' Association on the 11th inst., in reference to a claim made by the latter for a reduction of 12½ per cent. on the men's wages. The men's representatives asked for an adjournment to enable them to put the matter before the men in the district, and the next interview was fixed for the 21st inst. The masters stated that they were not prepared to make a less reduction than 10 per cent., to date from the beginning of the ensuing week. However, if the men wished it, the masters would agree to submit the matter to arbitration, the question to be determined being whether the reduction should be more or less than 10 per cent. At meetings of the men held this week the opinion was expressed that, following so close on the recent reduction of 5 per cent., the demand of the masters is unreasonable, and should be strenuously opposed.

SUNDERLAND, 15th April, 1891.

The Shipping and Coal Trade.—During last week 72,972 tons of coal were shipped, an increase of 29,992 tons over the previous week. 46,596 tons went coastwise, and 26,376 tons to foreign ports, as well as 1,104 tons of coke. Other coastwise shipments were 680 tons of patent fuel, 240 tons of steel plates, 100 tons of pig iron, 20 tons of cement, 76 tons of lime, and 13,000 dozen glass bottles. The imports for the same period included ten cargoes of timber, besides iron ore, silver sand, and moss litter.

Shipbuilding.—There is a revival in the building of sailing vessels, both of medium and great burthen. Recently Messrs. John Blumer & Co., North Docks, entered into four contracts for sailing vessels, and Messrs. Robert Thompson & Sons, Southwick, are building four of the same class of vessels. Messrs. Wm. Pickersgill & Son, Southwick, are also engaged in this class of work, and Messrs. William Doxford & Sons, Pallion, are at present fitting out a large four-masted full-rigged ship. The new National Line steamer "Europe" has been dry docked at this port, as none of the graving docks on the Tyne were capable of accommodating such a large vessel. This vessel has been built by Messrs. Palmer's Shipbuilding and Iron Company, Limited.

NEWCASTLE, 15th April, 1891.

The Coal Trade.—The demand for manufacturing and gas coals continues satisfactory, and prices are well maintained. Milder weather has, however, lessened the demand for household coals. There is only a small demand for "bunker" coal, but the early resumption of trade with the Baltic ports will cause an increased demand. A Shipowners' Committee has been appointed for the purpose of preparing a scheme of "minimum freights" for the coal trade, and a report on the subject will shortly be submitted to a general meeting of North-East Coast shipowners. The shipments of coal and coke at Tyne Dock during last week amounted to 94,491 tons, being an increase of 13,865 tons as compared with the shipments for the corresponding week last year.

The "Fielding" Gas Engine.—A depôt for the sale of the "Fielding" gas engine, which is manufactured by Messrs. Fielding & Platt, hydraulic and general engineers, Gloucester, has been established at 32, Collingwood Street, under the management of Mr. Gilham, who was formerly the agent in Newcastle of Messrs. Crossley Brothers, Manchester. Though the "Fielding" gas engine has only lately been introduced, the demand is already far in excess of the capabilities of production. The patentees, however, are now erecting extensive premises for the manufacture of these engines. Several engines of this type have already been sold, including a 16 h.p. engine, purchased by Messrs. Clarke, Chapman, & Co., Gateshead.

Government Contract.—Messrs. George Angus & Co. have for the fourth time obtained the contract to supply the whole of the leather hose required by the Admiralty departments for the next twelve months.

North-East Coast Institution of Engineers and Shipbuilders.—At a meeting of this Institution on the 10th inst., under the presidency of Mr. W. Richardson, the discussion on Mr. W. C. Mountain's paper on "Electrical Engineering" was continued, and turned principally on the comparative advantages of the systems of double and single wiring for electric lighting of vessels. Mr. Newitt gave the result of experiments with the single wire on board one of the Elswick cruisers, and said that with a wire 3ft. in a horizontal direction from the compass there was a deflection of 58 deg. The double wire system was preferable for three reasons—(1) In the single wire system there is double the chance of a break-down; (2) more danger of fire through bad contact with the ship and exposed wire eaten away by the salt water; (3) the serious effect upon the compass. The extra cost of the alternating current to avoid all this would in an ordinary ship not exceed £60. Mr. W. Hök then read his second paper on "The Unsinkability of Cargo-carrying Vessels."

Electric Lighting.—Messrs. J. H. Holmes & Co.'s works, Portland Road, are very busy, and new orders continue to be received. The firm have completed a very large number of steamship installations this year, and have carred out some important work in connection with the electrical equipment of two Atlantic liners.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

Industries:

FRIDAY, 17TH APRIL, 1891.

THE RECENTLY APPOINTED LABOUR COMMISSION.

WHEN a Government desires to shelve an inconvenient question, the appointment of a Royal Commission is a favourite expedient. Such a plan provides a safety valve, by means of which those who are over-zealous in a particular direction may blow off surplus steam; to those who clamour for the Government to do something by way of remedy for real or supposed evils it offers the appearance of action, while to those who disapprove of Government interference it offers the too obvious reality of doing nothing. It is a little absurd to regard the appointment of a Labour Commission as a new departure. During the past three-quarters of a century we have hardly been free from labour commissions, not, perhaps, explicitly so-called; but still labour commissions to all intents and purposes. The Factory Commissions, the Commission on the Employment of Children and Women in Agriculture, the Trades Union Commission, even the Commission on Depression of Trade and Industry, were all in fact, if not in name, labour commissions. It must be admitted that, save the last named, these commissions produced some good results beyond the publication of ponderous Blue Books. The contents of these mainly exist now for the bewilderment of German economists, who search their pages for evidence in support of some economic theory, or with the less worthy object of making a pedantic array of foot-notes. The terms of reference of the Commission on Trade and Industry of 1885 were so vague, and the general character of the quest so hopeless, that there was no practical outcome of its labours. The same may be said, as yet at all events, of the Commission on the Precious Metals of 1887, and the same may also be said of the terms of reference and the quest of the Labour Commission of 1891. These terms are similar to those of the Trades Union Commission, except that the commissioners in that case were instructed to inquire into the relations between employers and employed as regards the specific matter of combinations. While it is open to question whether or not a new commission on this subject is needed, one might have been more hopeful of the result of such a commission than of one which is instructed to inquire into any and every subject connected with industry. An open charter might, under some circumstances, have been an advantage, but the composition of the Commission is at once too heterogeneous and not representative enough to encourage much hope in this connection. We do not make serious objection to any of the names on the Commission, though a considerable number of the members might more fittingly have given evidence as witnesses. With the exception of two or three names, there are none of first-rate eminence, and the Commission as a whole, therefore, lacks weight. The parade, too, which has been made of its representative character is hardly justified. The mechanical trades are inadequately represented, Sir Edward Harland being representative at once of the industries of Ireland and of shipbuilding and engineering generally. There are five representatives of the coal and iron trades, two of the cotton trade, two of shipping, two of dock labour, one of gas, one of political economy, and one of jurisprudence, while shipbuilding and mechanical engineering of all branches in England and Scotland are absolutely unrepresented. Only one representative has been chosen to act for this group of industries, and, though a man of distinction, his interests are more specially connected with Ireland. A few of the nine politicians might, perhaps, have been spared to make room for one or more engineers having special acquaintance with the conditions of the engineering industries in England and Scotland. Mr. William Mather, M.P., or some other prominent engineer who takes an interest in the labour question might even yet find a place upon the Commission with universal acceptance. We are not so much concerned about the precise character of the possible good to be done by the Commission as of the possible evil it may do. It may raise false hopes, and point the way to a delusive short cut to class well-being. Its strongly marked antagonisms, however—eight representatives of capital against eight of labour, with two professors and nine politicians to arbitrate in the fray—give small promise of any result being attained. Is it possible that the Government has so concocted the mixture that the elements will mutually neutralise and sterilise each other? If this be the case, it is possible that this amiable intention may be frustrated, and that many of the politicians may side with the labour section and clamour for legislation of such a character as would sweep away the remaining vestiges of individual liberty. Even if the Commission is to do nothing more than elicit information upon the various industries of the country, this can only be done efficiently by the inclusion of representatives of all the leading industries, and not merely of a few of them. The engineering artisans, who make no clamour, who seldom strike, and who quietly and successfully attend to their own affairs, have been left unrepresented, while the railway men, dock labourers, and miners, who never cease to trouble with a grievance of some kind, are fully represented. And in the same way English and Scottish engineering capital is left out in the cold, as if it did not sustain one of the most important industries in the country. There is, for obvious reasons, no special hardship in this neglect; but there is a certain disadvantage in the omission. Nothing characterises the great engineering establishments of the country so much as their excellent organisation, and the demonstration of this fact before the Commission would perhaps go far to explain why it is that there are so few strikes and so little discontent in the mechanical engineering trades. High technical skill is essential in the leader of an engineering establishment, and generally inspires respect and loyalty on the part of the workmen. Highly skilled workmen, whose ordinary work involves the surmounting of continual difficulties, are usually easily managed. Their knowledge and experience cause them to be fairly reasonable in their demands. Revolts arising from defects in organisation are very few, and thus a large class in the whole category of strikes is almost obliterated. General panaceas by sanction of Royal Commissions or otherwise are ineffectual; but it seems worth while to point out that the high development of technical skill brings out qualities both in masters and in men that go far to solve by their merely spontaneous action the difficulties of the labour question.

THE BRAKE QUESTION ON SOUTH AUSTRALIAN RAILWAYS.

In the early part of last year the Government of South Australia appointed a Railway Brakes Board, consisting of the following gentlemen—viz., Mr. L. Grayson, M.P. (chairman), Mr. Thomas Roberts, locomotive engineer South Australian Railways, Mr. J. Quan, manager Glenelg Railways, Mr. Allison D. Smith, acting locomotive engineer Victorian Railways, and Mr. D. H. Neale, New South Wales Railways. The Board was appointed to inquire into the respective merits of the Westinghouse, vacuum, and other brakes. The report of the Board has now been published, and will form an interesting document to engineers and railway officials.

The Board conclude their report by recommending the adoption of the Westinghouse quick-acting automatic brake as the standard brake for the colony, or any other that may afterwards be proved to be superior that will couple with it. The result of the invitation made by the Board was that four brake companies declared their intention to compete. Three of them, however, withdrew, leaving only the Westinghouse Brake Company in the field. The Board decided notwithstanding to go through with their programme, and put this company's brake to practical tests. These tests took place on the 9th, 10th, and 11th October, 1890, between Petersburg and Jamestown. In framing the trial tests the Board kept in view the necessity of making experiments under the severest conditions that a rapidly growing traffic would be likely to bring into operation, and endeavoured to conduct the trials so that they should fulfil the following essential conditions:—(1) The behaviour of the brake should, as far as possible, be tested under all the various conditions likely to arise in ordinary practice; (2) the brake should be tested so as to show its merits and defects under both ordinary and unfavourable circumstances; (3) the results obtained at the trials should be accurate, and checked by an electrical automatic indicator and by independent observations. The Board also specially directed its attention to the following points in regard to the Westinghouse brake:—(*a*) Complexity, especially of the triple valve, and consequent liability to become injured by dust and grit; (*b*) graduating power; (*c*) liability to become exhausted by repeated application; (*d*) time taken to release; (*e*) frequency of burst hose pipe; (*f*) liability of pump to fail. On the points (*b*), (*c*), and (*d*) the brake was subjected to the most severe tests.

Repeated trials proved that a train heavy enough to require three engines on an ascending gradient could be safely taken down the steepest gradient (1 in 61) by one engine, the brake-power being entirely under the control of the driver, who could regulate the speed and stop when required. The liability to become exhausted by repeated application was tried both by running down inclines and repeatedly applying the brake, and also by applying the brake at intervals of thirty seconds when the train was standing in a siding. In the former tests the pressure at the foot of the incline was invariably higher than at the summit, showing that the brake gained rather than lost in potential power. In the latter test the pressure in the train-pipe fell 5lb. in six minutes, and, on making a stop with the diminished pressure, the train was stopped in 570ft. when running down an incline of 1 in 80 at 34½ miles per hour, showing an ample reserve of power. The release was quickly effected, the brake-blocks coming off all the wheels and the train starting from a state of rest in three seconds after the driver moved his handle to the release position. The stopping power in an emergency on the longest trains at maximum speed, as shown by several tests, proved that the train could be stopped in less than one-fourth the distance on the level with continuous as against hand brakes. The figures being for Trials 20 and 21 on the level, the continuous brake stopped the train in 377ft. from 34·5 miles per hour, whilst the hand brakes required 1,683ft. to bring it to rest from 32 miles per hour. The equivalent distance in which a similar train could be stopped when travelling at 40 miles per hour down a gradient of 1 in 60 would be 634ft. for the continuous brake and 11,592ft. for the hand brakes. The times, distances, pressures, and speeds were taken by an automatic recording apparatus, which, by means of several Richards indicators, drew diagrams of the pressures and speeds on an endless paper band driven from an unbraked axle of the rear van.

The Board regrets that the quick-acting automatic vacuum brake was not brought forward for trial, and that therefore its performance could not be judged from actual observation. The agent for the Vacuum Brake Company appeared before the Board after the brake trials at Petersburg, and handed in a report of a trial of their quick-acting brake which took place on the Manchester, Sheffield, and Lincolnshire Railway on July 21st, 1889. The trials, the Board states, appear to have been of a somewhat informal character, and the results given are too meagre to enable the Board to form any definite opinion as to the suitability of this brake for use on the South Australian railways. Two members of the Board, whilst signing the report, dissent to certain portions of it. Mr. Roberts, whilst favouring, for the 5ft. 3in. gauge, the adoption of the Westinghouse automatic quick-acting brake, which is almost exclusively used in the United States, recommends that communication be opened with the railway authorities of Queensland, and, if considered desirable, with Western Australia, with a view to adopting a uniform brake for the 3ft. 6in. gauge lines. These colonies have adopted the automatic vacuum brake, so far as they have fitted continuous brakes, which is not to a great extent. To this inquiry the Premier of Queensland telegraphed the reply that "some engines and carriages are fitted with automatic vacuum brake, but are not thought suitable for working long mixed trains, Westinghouse being considered better adapted. A few vehicles are about to be fitted therewith for sake of comparison, but no competitive trials are proposed between the rival companies."

THE INFLAMMABLE LIQUIDS BILL.

The announcement made by the Home Secretary in Parliament on Monday, that "The Inflammable Liquids Bill," to which we alluded in our issue of the 20th ult., would be withdrawn, is only what was to be expected when we take into account the opposition which the measure has aroused in Parliament and throughout the country. More than fifty members of the House of Commons, representing all political parties, were pledged to move its rejection, and if they failed in that, and the Bill reached its Committee stage, there seemed to be a prospect of amendments being proposed for every clause. We observed in our previous notice of the Bill that many of its provisions were very drastic, and that the country shopkeepers and the mineral oil manufacturers were up in arms against it. It may be the case that our present regulations are defective in some points of importance, and fall short of those of other countries, but at the same time it is possible, by a sudden change, to cause great hardships and inconvenience. The opponents of the Bill admit that some further legislation is necessary, but they contend that the provisions of the Bill are needlessly stringent and complicated, and, if passed into law, would cause great damage to an important and increasing industry, without ensuring any corresponding advantage to the public. The chief points insisted upon by the Home Secretary and his advisers are the absence of regulations at present for controlling the storage or conveyance of mineral oil, and of powers of universal application for securing the safe keeping of inflammable liquids, the defective character of the regulations for the conveyance of these liquids, and, lastly, of defective provision as to control by the local authority. In defence of the proposals contained in the Bill the Home Secretary has issued a Parliamentary paper of about 120 pages, in which he reviews the past history of legislation on the subject, and explains the grounds on which he has brought forward the Bill. This paper will be of great value in educating public opinion on the subject, and we trust that it will form a basis of agreement among those interested in the matter, and that another Bill will soon be introduced, which will sufficiently protect the interests of the public without hampering trade and industry.

THE SHIPPING FEDERATION AND INSURANCE FOR SEAMEN.

A scheme for the insurance of seamen has lately been organised by the Shipping Federation in order to bring about more satisfactory relations between employers and employed. It was felt that the Employers' Liability Act could be applied with difficulty to the shipping trade, and a definite scheme has now been formulated as the result of a discussion by the more important branches of the Federation. Every seaman or fireman who takes out a Federation ticket—for which a shilling is charged by way of registration fee—will, by reason of his possession of that ticket, and without any further payment, effect thereby an insurance of £25 in case he should be killed or lost at sea while serving on a Federation ship. In the case of captains the insurance—on the same conditions—will be £100, first engineers £100, other engineers £50, and mates £50. In the event of a Federation ship being lost at sea with all hands, insurance money to the amount stated would be paid to the legal representative of every man on board. The ticket itself, duly stamped, will be the insurance policy, and on it, probably, the holder will write to whom this money shall be paid, a duplicate ticket being kept at the shipping office in case of need. If any seaman or officer should wish to be insured for a larger sum this can be arranged by the Federation; but he would be required to pay for any insurance over the £25, which—but for the ordinary registration fee of a shilling—will be given gratuitously. The funds of the Federation are to be held responsible for the payment of the insurance money, and the Federation hopes to secure the services of a better class of men, and to obtain other advantages, from the fact that on taking out a "Federation ticket" the holders would be pledged to work both with union and with non-union men. The Federation would, moreover, obtain some security for the efficient discharge of duty on the part of the seamen, by the fact that they would lose all benefit from the scheme if they should be dismissed for any good reason. The exact details of the scheme are now being fully worked out by a committee of representatives of important shipping associations. In a correspondence published in the *Times*, between Mr. Chamberlain and Mr. Martin, one of the members representing the Clyde district of the North of England Association, the former suggested that the proposed provision is not sufficient, but should include a superannuation or annuity after a certain age. Mr. Chamberlain pointed out that a plan of this sort has already been tried by the Great Eastern and other railway companies. Mr. Martin, in reply, points out that the nature of the service differs from that on railways. "A man may enter the employment of a railway company and work in its service for a lifetime, having his share of the annuity fund regularly deducted from his wages, whereas sailors are a floating population, seldom serving twice on board the same vessel, or for any length of time in the employment of the same shipowner." A suggestion has been made that the insurance of £25 should be so arranged as to include sick pay in case of disablement, but no definite decision on this point has been arrived at. Mr. Martin states that the Shipping Federation has an anxious desire to establish good relationships with its men, and no effort will be spared to establish a broad and liberal assurance scheme for the benefit of its employés.

COAL, IRON AND COGNATE INDUSTRIES.

Since our last review of these industries their general position has undergone a material change for the worse. Values in every branch have fallen, and it is generally recognised that iron manufacturers are now working at an absolute loss. In order to fully gauge the situation a brief retrospect is desirable. From December, 1888, to January, 1890, prices rose rapidly, wages being proportionately advanced. A reaction in values, however, occurred, to which no check has at present been experienced. Curiously enough, where no sliding scale was in operation, the organised forces of labour even during the reaction succeeded in obtaining higher rates of wages—two advances of 5 per cent. each being conceded to colliers and ironstone miners in March and August of last year. At the highest point pig iron was sold at 65s. to 72s. 6d. per ton; bar iron was worth £9 per ton, the value of these commodities affording a fair index to the general trade. In comparison, their present prices stand at 40s. to 45s. and £6 per ton respectively. The published balances of public companies connected with these industries showed that 1890 proved a fairly prosperous time for proprietors, the first half of that year reaping the full benefit of contracts entered at the highest rates. The present position is that, while prices all round have fallen to the extent already indicated, the cost of labour remains practically at the highest point. There appears little, if any, immediate prospect of a higher level of prices, and several works have been brought to a standstill through the anomalous relation of costs and selling values. The eventual outcome is inevitable; the cost of the raw materal must be reduced, and this can only be effected by a reduction in wages. The Board of Trade returns for March and the first quarter of the year clearly indicate the serious state of our export trade, and the quarterly meetings recently held are equally conclusive of the falling off in the home demand in connection with the industries under review. The question as to why this anomalous position is allowed to exist presents a curious social phenomenon. On the one hand, labour organisation has attained a high state of perfection, and Parliamentary sympathy with the working classes is very strong, while on the other hand combinations of capitalists and manufacturers are comparatively weak, and competition so keen, that in any struggle between the two forces the chance of victory is in favour of the former. The result is that with the exception of a few recent strikes, which have been fought at enormous cost, matters are being permitted to take their own course, the weakest firms are going to the wall, at nearly all works short time is adopted, and the trade of the coun-

Digitized by Google

try is becoming paralysed. At the present time the relative position of value and cost is worse than at the lowest state of the previous trade depression, and therefore we may regard the position as somewhat alarming.

The maintenance of high prices for coal for shipment has exercised a large influence in keeping wages up, but bearing in mind the enormous quantity of fuel raised in inland centres and utilised in the production of iron and steel, we feel convinced that a proportionate adjustment of the cost of labour to selling values of the finished product will shortly become a necessity.

THE BOILER INSPECTION AND REGISTRATION BILL.

On the 21st inst. an endeavour will be made to pass the second reading of a Bill for the Registration and Inspection of Boilers. This Bill has been introduced to the House by Sir William Houldsworth, Mr. Maclean, Mr. William Mather, and Mr. Burt. It is understood to have been prepared by the Steam Users' Association of Manchester, but from its character we should not assume that it has the approval of the members of that body, but merely that of its officials and committee. In fact, there is little doubt that if the majority of the members of that Association were fully alive to what is being done under their name they would object to the present Bill as a whole. Last year a Bill having the same support was introduced by Sir William Houldsworth, but, as it was pretty clear that its main object was simply an attack upon existing boiler insurance companies, it has been allowed to drop to make room for the present Bill.

Before any legislation is effected, it would be well to carefully inquire what is the necessity for a Bill of this kind, and what is the extent and importance of the support given to the suggested legislation. It appears from the returns of the Board of Trade that accidents to persons from explosions occurring to boilers, kiers, steam pipes, &c., have for the last few years been reduced to an annual average of about thirty-two killed and fifty-seven injured. Of these it appears, from an examination of the Board of Trade reports upon the causes of boiler explosions, that about one-third are due to what may be called non-preventable explosions, which no system of inspection could have averted. When the enormous extent of steam generating operations in this kingdom are considered, this death-rate is not alarming when compared with the number of accidents which occur in many branches of industry not nearly so extensive in their character. For instance, it would appear from the return of railway accidents that, for the year ending 31st December, 1889, there were (after deducting eighty-four suicides) no less than 992 persons killed and 4,386 injured. There were also, during the twelve months ending October 31st, 1889, no less than 443 persons killed and 7,524 injured in the various factories and workshops in the Kingdom. In various collieries and mines during 1890 there were 1,206 killed, exclusive of a large number injured. From private but reliable statistics, to which we are able to refer, it appears that among an average of 266,302 persons employed during each of the past ten years in workshops of various kinds, a total of 302 have been killed and 11,913 have been injured. Of these only three were killed and six injured from any accident arising from steam generators during the whole ten years, or one person killed per annum in every 887,000 persons employed. It would appear, therefore, from these figures that, with a view to reducing loss of life and injury to workpeople and other persons, further legislation is more urgently required in regard to the working of railways, collieries, mines, workshops, factories, &c., than with regard to the use of steam.

With regard to the extent and nature of the support given to the proposed boiler legislation, it would be found that it is of a comparatively unimportant character, and centralised in the officials and committee of the Steam Users' Association. There has been no decided public call for action in this direction. With trifling exceptions, no notice has been taken of the matter by the press of the country. The majority of the Chambers of Commerce which have considered the matter have pronounced against any further Government interference at present with the steam using public, notably the Oldham Chamber of Commerce, which has expressed its opinion, not only on the present Bill, but on former Bills, in unmistakable terms. In short, the Bill is suggestive of an attempt to extend the business of the boiler inspecting associations at the expense of the public by means of Parliamentary interference. If such a Bill were passed there would naturally be a very large number of boilers to be inspected, and as the matter would require immediate attention existing associations would be likely to obtain the business.

The Boiler Explosions Act of 1882 has only been completely put in force since August, 1889, and already the number of explosions has fallen to a large extent. A few years' further trial of the present Boiler Explosions Act, properly enforced, will probably effect all the improvement that is conveniently possible in this direction, and it is therefore undesirable that further legislation should impose unnecessary restriction upon the boiler owner or steam user either in regard to the design or working of steam boilers.

We are behind no one in demanding that public safety should receive all the aid that legislation can give, but we object altogether to vexatious and unnecessary measures which tend to harass industry. In short, the position we take up on this question is that expressed a short time ago by Sir Michael Hicks-Beach—namely, "that a continuance of the policy of Formal Investigations may render further legislation practically unnecessary. . . . At any rate, it was a policy which should be persevered in, and its results ascertained, before any further legislation was attempted. . . . Publicity and penalties would do more good than anything Parliament could do."

We have nothing to say against the registration part of the Bill, as it is possible that the returns obtained would be useful for statistical purposes.

Letters to the Editor.

THE USE AND ABUSE OF MATHEMATICS.

To the Editor of "Industries."

Sir,—When first I read "Electrician's" letter on this subject it seemed to me to have been written in a fit of splenetic humour, and to contain nothing more than a cynical depreciation of man in general, and the "college man" in particular. As, however, universal disparagement is a sure sign of mediocrity in its author, and as "Electrician" is evidently a man who combines in himself the qualities of the true theorist and practical man, it might be worth consideration whether there is not some foundation for the writer's criticism on mathematics and mathematicians. It might further be advisable to consider what practical steps can be taken to ensure that mathematicians shall be more in touch with the actual work and needs of engineers, and not merely concerned with investigations on such problems as deal with "an elephant without weight spinning on the point of a needle," &c.

In the first place, mathematics in its most developed branches is largely an inductive science, and its extension depends on habits of accurate observation and comparison; in short, the study of mathematics may be said to exercise all the faculties of the scientific mind. That such views as these of the nature of mathematical study are held by Sylvester and Cayley, and Henrici, and other eminent mathematicians, and may be found in their presidential addresses to Section A of the British Association, is a proof that the study is something more than "concentrated deductive reasoning about quantity," and is in reality "a very high intellectual exercise."

After some questioning of the superiority of Cambridge mathematicians, the writer hopes that "some one may write a book on practical mathematics which contains just those subjects which are necessary for engineers." Now, apart from the fact that "the useful is only a small part of the important," as Goethe somewhere remarks, I venture to think that the attempt to write such a book would only end in failure. Nature, as shown, for instance, in the working of a dynamo, is not simple, but highly complex, and as mathematics should be the symbolical representation of laws of nature, it follows that the practical mathematics recommended by "Electrician" would also be highly complex, and could not be entirely apprehended without a study of much that seems unpractical. In short, Euclid's remark that "there is no royal road to learning" remains as true now as it was two thousand years ago. As to the importance of graphical solutions of problems, the Cambridge man would probably agree with "Electrician."

It is, however, to the intended establishment of an engineering school at Cambridge, as advocated by Professor Stuart and by Professor Ewing, that we must look for help towards making mathematics more practical. This measure will have an important effect in various and, perhaps, unexpected directions. Intellectual activity is not incompatible with mechanical expertness—nay, it may possibly be assisted by it. The study of nature in her actual working is essential to the advancement of applied science, and will, perhaps, teach the "college man" that modesty, of which "Electrician" is so anxious to see him possessed, by showing him how difficult it is to find complete mathematical explanation of all the facts observed. The mathematician must become an engineer, and the engineer must become a mathematician.

Yours, &c.,
Ne Sutor Supra Crepidam.

London, 9th April, 1891.

To the Editor of "Industries."

Sir,—The letter from "Electrician," which appears in your issue of the 3rd inst., on the subject of "The Use and Abuse of Mathematics," sets forth a very sensible view of a subject which is of great importance to engineers, but if he had been, as I have been, a constant reader of your journal, he would have seen that the opinions he expresses agree with those which have appeared in the leading and educational articles which have appeared in *Industries* from the very first. You have always insisted on a combination of theoretical and practical knowledge, not only for the engineer, but also for the physicist and mathematician.

I believe that at the social meetings of a certain society in London the toast "Success to pure mathematics, and may it never have any application," is very often proposed amidst great enthusiasm, and I must say that to a certain extent I sympathise with the sentiment, which in this case may be carried to an extreme, but which generally means that knowledge should be sought for its own sake, and not for the pecuniary gains or practical applications which are likely to result. Some of the most valuable discoveries in the leading departments of industry have flowed either directly or indirectly from the researches of men who never allowed pecuniary or practical considerations to influence them in the smallest degree. The name of Faraday, for instance, only requires to be mentioned as an example of a man who had no time to make money, and who had no desire to be rich, and yet he laid the foundations of the modern science of electricity with its ever-increasing applications. He was almost entirely ignorant of mathematics, but he wrote and spoke in mathematical language, and, in fact, taught the mathematicians how to interpret their own expressions, and to clothe with living meaning the abstract formulæ which they had ground out of their mills by a mere mechanical process. But it cannot be doubted that even Faraday would have been a great deal the better for at least a certain amount of practical as well as mathematical training. It is well known that the most important developments in the theory of electricity have been the direct results of investigations made in connection with practical applications.

We cannot expect a scientific man, who devotes the greater part of his time to theoretical investigations, to keep himself acquainted with all the developments of practice, nor can we expect a practical man largely absorbed in business to know all about the latest theoretical investigations relating to his department, but each should try to keep up in the main lines of development. For the practical engineer there can be no doubt that Professor Kennedy was right when he said some years ago that he had "no hesitation in saying that a man's knowledge of mathematics ends exactly where his ability to work problems ends; anything beyond that is useless, so far as his profession goes, and is even liable to have, in certain cases, disastrous consequences."

Professor Osborne Reynolds, at a somewhat later date, put the matter very clearly when he said, "All the more useful branches of science are now within the reach of the student of engineering, and in the forms most suitable for him. So that as a step towards understanding the theory of machines, it is not now necessary for him to begin with the theory of astronomy or the doctrine of chances. The miserable form in which the only mathematics to be obtained was wrapped has compelled engineers to work out methods for themselves, and now that the demand for such knowledge has increased, we find that the first mathematicians in the land have, so to speak, patronised our system. And as is natural, the extension of the practical use of mathematics has infused new life into their study. Learnt as it now may be, with a special view to the application of practical mechanics, a knowledge of mathematics and science is much more useful than it was. But this is by no means all. This would not be much were it not that the accumulated experience of engineering work has to a great extent been systematised and reduced to a form capable of mathematical treatment."

These opinions express the proper use to be made of mathematics, and also indicate how the study of the subject has been abused by those who were engaged in it, and who underrated the importance of all others.

Yours, &c.,
Teacher.

Glasgow, 8th April, 1891.

THE ENGLISH ULTRAMARINE INDUSTRY.

To the Editor of "Industries."

Sir,—In your annual review of the Chemical Industry for 1890, in your issue of January 9th last, you recommended that attention should be given to the manufacture of ultramarine in this country. There is no doubt that this view of the English industry—at a time when all the German ultramarine manufacturers have formed a "ring," and are endeavouring to cultivate trade in all parts of the world—is a correct one, and in accordance with the spirit of the times. Why should England, who, as I show below, imports and consumes nearly half of the whole of the German production of ultramarine, not endeavour to supply its own wants and thus become independent of Germany? The necessary raw materials, such as china clay, sulphur, soda ash, and rosin, may all be obtained in England cheaper than in Germany, and the difference in wages paid in the two countries is not of importance. The belief that the English climate is not suitable for the manufacture of ultramarine is altogether a wrong one.

The following table gives the total exports of ultramarine from Germany in the years 1889 and 1890, and also shows the quantity imported into England from Germany:—

	1889.		1890.
German exports of ultramarine	5,283 tons.	...	5,258 tons.
Quantity exported from Germany to England.....	2,005 ,,	...	2,076 ,,

To this amount is to be added the imports from Austria, France, and Belgium, which are not altogether insignificant. Taking the price of ultramarine at £25 per ton, England pays annually to Germany about £51,900

I conclude this short letter with the hope that English chemical manufacturers will consider it to their advantage to give greater attention to the manufacture of ultramarine in this country.

Yours, &c.,
Ultramarine.

Hull, 9th April, 1891.

THE SHIPS AND ENGINES OF THE NAVY.

To the Editor of "Industries."

Sir,—I hope the suggestion made by a correspondent in your issue of the 3rd inst., regarding the information which might be supplied by the Admiralty about the ships and engines of the navy, will be taken up by some energetic M.P. who is able to take an intelligent interest in the matter, as I have long felt that engineers and shipbuilders might thus receive a great deal of information which would be most valuable to them. Lord Randolph Churchill has evidently been primed by someone regarding the necessity for the report mentioned by you a short time since, but your

correspondent in his letter indicates many other points which might be attended to with great advantage. For some years past I have been particularly interested in one department on which I find it impossible to obtain any definite information—I mean, the friction of the mechanism of marine engines. We have gone on improving the methods of using the steam in the cylinders and measuring the indicated horse-power, but we know little or nothing about the relation of that to the brake horse-power, or to what is generally called the effective horse-power in the case of a marine engine. Froude's figures, which he gave a good many years ago, were largely hypothetical, and, moreover, the types of engines and ships have been entirely changed. The only systematic experiments the results of which have been published are those by Taurines. These were made nearly thirty years ago, but it is only seven years since they were awarded a prize by the Academy of Sciences, which looked very much like an afterthought, possibly owing to the growing interest in the subject. They were thereafter printed and published by Gauthier-Villars, of Paris, and are very interesting in their way, but they are altogether out of date, both ships and engines having been revolutionised in the interval. The experiments were carried out at the expense of the French Government, and I am afraid, unless the British Government takes up the matter, it is too much to expect any private persons, or even any engineering association, to do so. What your correspondent says about life on board a man-of-war is quite true—there is not very much of an intellectual nature about it, and work of the kind suggested might be the means of attracting to the service and keeping them in it men who were not only good practical engineers, but who were also imbued with the true scientific spirit.

Yours, &c.,
London, 9th April, 1891. ANOTHER M.I.N.A.

"GUTTMANN'S" NITRIC ACID PLANT.

TO THE EDITOR OF "INDUSTRIES."

SIR,—Since the publication of your description of this plant in *Industries* of the 5th September, 1890, a twin battery of nitric acid condensers has been erected, and been in nearly constant work for more than two months. The working of these batteries has been purposely left entirely in the hands of the foreman and his workmen, in order to see how soon they would become accustomed to the altered method of working. It was found that on the second day the work went on without a hitch.

The above table summarises the results obtained.

At the dynamite factory where these results were obtained it is most important that the acid should have a maximum of monohydrate, whilst 1 to 2 per cent., more or less, of hyponitric acid is of no importance, so that no precautions have been taken to keep the percentage of this down to a minimum. At the same time it is essential that the battery should exclusively condense acid of the highest concentration, and weak acid should only be produced in the tower.

The average loss of 7 per cent. is composed of—(*a*) the acid remaining in the nitre cake; (*b*) the hyponitric acid formed; (*c*) the acid from the tower; (*d*) the small remainder which escapes into the chimney.

The tower acid has no value at the factory above mentioned, and it is therefore not collected, but in factories where weak acid (of between 1·300 to 1·400 sp. gr.) can be sold, nearly the whole of the quantity shown under "loss" can be recovered, since the Lunge tower only allows traces of gases to escape uncondensed. It depends, of course, upon the attention of the workmen how large the loss is, and, with greater care in working, the average mentioned here will be found to be much too high.

The influence of the Lunge tower upon the yield was forcibly shown, when, in consequence of an exceptional frost, the water pipe leading to the tower burst, and could not be repaired for some time. Of course, the draught on the battery became, in consequence, much larger, and it was, in spite of every precaution, impossible to heat so slowly as to prevent part of the gases from escaping uncondensed into the chimney. Under these adverse conditions, only 4½ per cent. more than usual was lost, and the amount of hyponitric acid present rose but slightly.

The time for the distillation has now been reduced to ten to eleven hours for a charge of 12 cwt. The pottery material used by the manufacturer of this plant (Mr. Ludwig Rohrmann, of Krauschwitz, near Muskau) permits the tubes to be made with a thickness of $\frac{3}{8}$in. (9mm.) only, in spite of their great length of 8ft. 4in. (2·50m.). The battery has, in consequence of these very thin tubes, a largely increased condensing power. It is also evident from the experience gained that these tubes withstand high temperatures much better than those of the ordinary thickness; on some occasions the fire was by accident continued so long that only sulphuric acid condensed in the batteries, and the charge was finished in nine hours or less. Such a short duration is not desirable, on account of the large wear it entails upon the retorts, and the distillation is now simply regulated by leaving the last tube cold and the last but one warm. In this case a minimum of gases escape into the tower, and the time of distillation is, as before mentioned, ten to eleven hours.

The joints behave in a very satisfactory manner, and, as they are all either vertical or at an inclination of 45 degrees, there is no dripping. The battery is so mounted that the long tubes can expand quite freely.

The acid obtained on different days has been repeatedly analysed by Messrs. Bate and Sandford, and has always proved to be free from chlorine, iodine, sulphates, &c. The residue calcined after careful evaporation was always $\frac{30}{100000}$ per cent., consisting of $\frac{2}{100000}$ per cent. PbO and $\frac{28}{100000}$ per cent. Fe_2O_3. The excellent quality of the acid may be seen from the fact that, after having removed the hyponitric acid, this acid is used with very good results as chemically pure nitric acid in the laboratory.

Yours, &c.,
OSCAR GUTTMANN.

Dunster House, Mark Lane, London, E.C.,
9th April, 1891.

THE LATE MR. BENJAMIN WALKER.

WE regret to record the death of Mr. Benjamin Walker. Mr. Walker died on Tuesday, the 14th inst., in his 71st year. He was a member of the Institution of Civil Engineers, a member of the Council of the Institution of Mechanical Engineers, and of the Iron and Steel Institute. In 1862 he started an engineering works in Leeds, which has since become one of the largest establishments of the kind in the world, and became the head of the firm well known as Messrs. Tannett, Walker, & Co. His earliest training as an engineer was undergone in Leeds, and at the age of twenty he was foreman to Messrs. Kitson, Hewitson, & Thompson, of Leeds, who were among the very earliest builders of locomotives. Subsequently he was engaged to start the works at Belfast now known as Messrs. Combe, Barbour, & Combe's. His career as an inventor began by his bringing out a self-acting motion for steam hammers and the wrought-iron wheel now universally used for traction engines, instead of the old-fashioned wooden wheel with a metal tyre. The slotting machine was also patented by him. Mr. Walker, at a very early period, became associated with the Bessemer process. In 1863 he proposed to a Sheffield firm of steel producers the use of a forging press instead of the steam hammer, but nothing came of the suggestion until a few years ago, when some more potent means of dealing with great masses of steel were necessary than those which had heretofore been used. The use of such forging presses has made the work of manipulation now comparatively easy. These presses have been made by the late Mr. Walker's firm for all the European Governments, and are employed in forging guns and doing other heavy work in several arsenals.

Legal Proceedings.

TUCKER *v.* KAYE.

IN our issue of the 27th ult. we reported this case, and in doing so remarked that the learned Judge—Mr. Justice Romer—who tried it had apparently taken a severe view of the patent, inasmuch as he decided against the plaintiff upon the double ground that the patent was invalid and the alleged infringement unproved, although the latter ground alone would have been sufficient to support the decision, and appeared to be, as we then observed, unassailably strong. The case has now been considered by the Court of Appeal, the plaintiff having decided to carry his complaint before that tribunal. He was represented, as in the Court below, by Mr. Bousfield, Q.C., and Mr. Reid; Mr. Aston, Q.C., Mr. H. Greenwood, and Mr. Waugh appearing for the respondent.

The decision at which the Court of Appeal has arrived confirms quite curiously in detail the view which we at the time expressed. We then remarked that the strong view taken by the Judge, which led him to pronounce, without any pressing need to do so upon the validity of the patent, was, in comparison with the practice of his judicial brethren, somewhat unusual. The Court of Appeal appear to have taken the same view, for, although the respondents were not called upon to answer the arguments of the appellant's counsel. Lord Justice Lindley, in giving judgment in their favour, expressed a guarded opinion upon the question of the validity of the patent, and said that he preferred to base his judgment upon the ground of non-infringement. Lord Justice Bowen concurred in this judgment, so that, although Lord Justice Kay expressed an opinion that the other grounds on which the action had been resisted were equally well founded—that is to say, that the patent sued upon was invalid for want of novelty, and particularly by reason of Wilson's anticipation of its principle—it is nevertheless clear that the weight of judicial authority is in favour of that tender treatment of patent rights of which we spoke as characteristic of our present jurisprudence. This favourable inclination towards an inventor is, we think, the right attitude of mind for the judicature to assume in such matters. The risks of patenting are serious enough as matters stand. The patent law would ill serve the public interest if it were administered in a hostile temper towards the rights which it creates, and, although it is of prime importance that patentees should not be put in a position to harass their neighbours with groundless or vexatious charges of infringement, it is a matter of importance only second, if second, to this that the patentee's rights, when acquired, should be both substantial and secure.

THE SKILLED LABOUR MARKET.

ACCORDING to the returns sent in to the Board of Trade by twenty-two unions of skilled workmen, with an aggregate membership of 245,772, 7,000 men, or 2·8 per cent., were out of work in the month of March, as compared with 6,149, or 2·6 per cent., in the preceding month. In March of last year the percentage of unemployed was 1·7. The number of strikes in February was 116, whilst in March there were only 53, of which 17 occurred in the cotton trade and 8 in the coal trade. The demand for skilled labour is generally less strong, but the building trade shows an improvement as compared with a year ago. The shipbuilding trade also continues firm, which must be accounted for by the large amount of repairing and converting work now being carried out. The reduced amount of new shipping would otherwise have caused a falling off. The engineering trades remain fairly steady, and the proportion of men out of work has only slightly increased. In the general iron trade more men are out of work than there were a few months ago.

Reviews.

ELECTRIC LIGHT INSTALLATIONS. By Sir David Salomons. London: WHITTAKER & Co. 1891.

This is the sixth edition, and is very much the same as the fifth. There is an additional chapter, and an introduction, which is a reprint of a magazine article. There are still many slips, and it would be wise for the author to have his proofs read before publishing, on the principle that two heads are better than one. The slips are not, however, generally important, and the book is full of practical points.

THE ELECTRICAL TRANSMISSION OF ENERGY. By Gisbert Kapp. London: WHITTAKER & Co. 1890.

This is the third edition of Mr. Kapp's well-known work. It would be difficult for anyone to guess the contents of a book with the present title; but most of the work is outside the limits of the subject proper. This is, however, no fault, and the book contains a great deal of valuable information about dynamo design and kindred matters. If such a thing could be done, we would suggest that when the next edition is called for, as we think it soon will be, Mr. Kapp should alter the title, and make it a book on dynamos and motors.

MAY'S POPULAR INSTRUCTOR FOR THE MANAGEMENT OF ELECTRIC LIGHTING PLANT. By Dr. Oscar May. Frankfort. 1891.

This is a little book containing succinct and clear instructions to the practical man who has to look after dynamos, secondary batteries, and private installations generally, and, if he absorbs all the information in this small work, and follows all the recommendations given in it, he will do very well. The translation from the German has been placed in the able hands of Mr. O. Berend, and the printing has been done in Germany. The "Electrician" Publishing Company are agents for England.

TREATISE ON CHEMISTRY. Vol. III. ORGANIC CHEMISTRY. Part III. By Roscoe and Schorlemmer. London: MACMILLAN & Co. 1891.

The authors of this well-known treatise are determined to keep their book well up to date. The present volume has been prepared by Dr. H. G. Colman, and consists of a revised edition of the old volume on "Aromatic Chemistry." It includes an admirable introduction to aromatic compounds, discussing the modern views of isomerism and the simple derivatives of benzene, including the recent researches of Nietzki and his assistants on the higher substitution products of this hydrocarbon.

VENTILATION, AIR TESTING, &c. By W. P. Buchan. London: CROSBY LOCKWOOD & SONS. 1891.

This little volume is one of considerable value and interest, and places before its readers, first, the various means by which the atmosphere may become contaminated in our dwellings. It then describes the older and more faulty systems of ventilation, and, finally, those now adopted in schools, workhouses, dwellings, and hospitals. Upon the whole, the author advocates natural in preference to mechanical systems of ventilation, but he is by no means biassed, and he places the good and bad points of each system fairly before his readers. It may be thought unfortunate that he has in several instances, perhaps unduly, praised apparatus of his own invention. In the section upon the ventilation of drains the system shown is of a much more elaborate character than is necessary, rendering it most complicated and expensive, although nothing can well be said against its efficiency. A chapter upon railway carriage ventilation, and another upon the methods of examining the air of buildings for impurities, will be read with considerable interest.

AIDS TO PRACTICAL GEOLOGY. By Grenville A. J. Cole, F.G.S. London: C. GRIFFIN & Co.

This book is intended by Professor Cole as a companion to the ordinary text-books of geology, and he hopes that it may be of special service to the student for determining the results of his excursions into the field. In our opinion, it will not only do this, but it will also be of the greatest possible use to travellers, to explorers, and to miners and prospectors in their search after ores and minerals. All theoretical matters are excluded, and the work is solely confined to the practical side of geology. The book is divided into four sections:—(1) The sampling of the earth's crust; (2) the examination of minerals; (3) the examination of rocks; and (4) the examination of fossils. The first part deals with field operations generally and the treatment of specimens; this section may fairly be said to bristle with useful "wrinkles." The examination of minerals with wet reagents, with the blowpipe, and by the other usual means is dealt with sufficiently fully to enable all the ordinarily occurring minerals to be identified. Micro-chemical reactions also take a prominent position. The examination of rocks is similarly dealt with. Directions are given for determining their physical properties and for isolating their constituents. A condensed list of minerals and of the several varieties of rocks are given in such a form that, for the purpose of the prospector, all other books might easily be dispensed with. The last section in the book is devoted to fossils, and here the author gives such a description of the hard parts of fossil invertebrates that the determination of most fossils is rendered practical as far as necessary for approximating to the age of the strata. The book is replete with practical hints, and contains an enormous amount of useful matter condensed within its pages, the whole being written in a thoroughly clear and scholarly manner, and elucidated by the aid of numerous well-drawn diagrams. A valuable feature is the addition of a short bibliography to each section.

PROPOSED NEW WATER SUPPLY FOR BIRMINGHAM.

IT has been determined by the Water Department Committee of the Birmingham City Council to apply for powers to carry out a very extensive new scheme of pure water supply from the Welsh mountains surrounding the upper basin of the Wye. The population of Birmingham has grown so fast, and its consumption of water is increasing so rapidly, that the Engineer of the Water Department, Mr. J. W. Gray, reports that the present sources will become inadequate to meet the demand in three or four years, even if they be developed to the fullest extent they are capable of. In 1876 the average consumption throughout the year was 8·30 millions of gallons per day; in 1881 it was 11·42; in 1886 it became 12·95, and went up to 14·28 in 1889. At present the maximum daily consumption goes up to very nearly 20 million gallons.

The present supply is from five watersheds, all situate in the comparatively flat and low-lying country to the east and north-east of the city. The total area of these is 111 square miles, and in this are built no less than thirteen reservoirs, with a total storage capacity of 618 million gallons. It is pumped up to a certain level, from which it flows by gravitation to the lower part of the city, and is thence pumped in two stages to the higher levels. An additional supply is obtained by pumping from seven deep wells in the New Red Sandstone. The minimum yield of these sources is 17½ million gallons per day, and as years go by the quality is sure to deteriorate, partly from being overworked and partly from the steady increase of population and farming industry spread over this district. So long ago as 1871 Sir Robert Rawlinson, who was consulted at that time by the Corporation, pointed out that these works could not be given a character such as to permanently supply the needs of Birmingham, and suggested the desirability of going west of the Severn Valley for a supply, the purity of which could be depended on as permanent, and the quantity of which might meet the demands for the next fifty years and more. The Corporation has now come to the conclusion that it would be wasteful expenditure to further bolster up the existing works, seeing that in all probability they will at no very distant future date have to be abandoned, either partially or wholly, at least so far as the supply to Birmingham itself is concerned.

The new gathering ground now selected has to its nearest point a distance of rather over eighty miles from Birmingham. It is the same as was recommended by Sir Robert Rawlinson in 1871. At that time Mr. J. Mansergh was Sir Robert's assistant in this investigation, and it is Mr. Mansergh who has now been consulted by the Corporation, and has recommended the present scheme. Bewdley lies about twenty miles west of Birmingham on the Severn. Almost exactly due west of Bewdley at fifty miles distance the river Elan joins the Wye in Radnorshire. At the junction the Elan flows nearly due east, and three miles above this junction with the Wye it is joined by the River Claerwen. These two drain an area available for Birmingham supply of 39,700 acres of almost uninhabited mountain-land (at present there are 180 persons living on it), the elevation of which varies from 800ft. to 2,100ft. above mean sea level. This height is sufficient to run the water by gravitation for eighty miles to the Monument Road Reservoir in Birmingham, the height of which is 532ft. above sea level, and from this service reservoir the water flows easily to nearly the whole of the city, the Aston reservoir, which is in the lowest part, being 235ft. lower. For the higher district of Edgbaston, the water is pumped from Monument Lane to a small covered service reservoir 70ft. higher. The quality of the water from the new district is the finest possible, containing less than 8 parts in 100,000 of total solids, only ·017 in 100,000 of organic nitrogen, the ammonia and sewage contamination being nil, and the hardness only 2·3 grains of bicarbonate of lime per gallon. Samples of the water have been tested by various experts, and it is found not to be injuriously affected by lead, so that no difficulty with the ordinary kind of service pipes will arise.

According to Rawlinson's plan, the highest reservoir to be constructed on this district would be 960ft. above O.D., and would store 540 million gallons; two others, at slightly lower levels, would store 1,160 millions; and yet two more would store 840 millions. These together give 2,540 million gallons. According to a rough estimate made by Mr. Mansergh, who is now asked to prepare a scheme for a larger supply than that contemplated in 1871, a site for a single large reservoir storing something like 4,000 million gallons exists in the valley of the Elan the dam being placed at a point 700ft. above O.D. This would be a compensation reservoir, and supply reservoirs would be constructed at various higher levels as the increasing demands of the city necessitated. The mean annual rainfall from a gauge near the lowest levels is 64in., this being taken from twenty years' observations. Mr. Mansergh puts the average at 66in. over the whole area, and calculates that at least 40in. could be collected. The 40in. over 39,700 acres gives an annual supply of 36,000 million gallons, or an average daily supply of 98·6 million gallons, from which has to be deducted a percentage for compensation, and a further percentage for evaporation and other waste. In 1890 the supply was 5,740 million gallons, and the rental about £133,000.

The present scheme is being laid out on the supposition that fifty years hence the needs of the city will have increased to 60 million gallons per day, the present rate of growth of the consumption being about 3 per cent. per annum. To finance the scheme it is calculated that the water rental, which is now £133,000, would by its natural growth be double this amount in the year 1913. An addition to the water rates is proposed which would make the water rental amount to £164,000 in 1892, and increase to just over £300,000 in 1913. A first rough estimate of the cost of carrying out the new scheme is given by Mr. Mansergh—viz., £4,000,000—and this expenditure would be spread over not less than ten years from 1892 to 1902. The proposed income would exceed the expenditure up to about 1898; from that time until about 1908 there would be a deficiency of income; and after that date there would be a rapidly increasing surplus of income. This calculation includes payment of interest on the expended capital and provision for the paying off of each portion of the debt thus created within sixty years of its being contracted.

The conduit is not yet designed in any detail, but throughout the higher parts of the line the water will flow in a masonry culvert of section sufficient for 60 million gallons per day. The length of this is estimated at about 44½ miles, of which 8¾ miles will be tunnel. Where the line descends into valleys and crosses rivers the water will be conveyed by steel pipes, and about 34½ miles of these will be necessary. There will be five such pipes, each 45in. in diameter, only two of which will be laid on the first construction of the works, the others being added as they become needed. At some point about half-way between the Elan and Birmingham, a reservoir of 100 million gallons capacity will be constructed. The chief rivers to be crossed on the route are the Wye, the Ithon, the Teme, the Severn, and the Stour. No opposition to the scheme has manifested itself, and the vote of the City Council to be taken on the 21st inst. is expected to be unanimous in its favour.

ELECTRIC CRANES.

MR. W. D. SANDWELL recently read a short but interesting paper on this subject before the South Staffordshire Institute of Iron and Steel Works' Managers. Electric cranes only want exploiting, like most electric motor work. With few exceptions nothing can be worse, from the point of view of cost and efficiency, than the ordinary form of travelling or overhead crane. In a works, such, for instance, as an erecting shop, the crane is generally driven by an endless rope or by shafting and bevel wheels, with more or less complicated bearing arrangements. Even when lifting a very heavy weight such an arrangement is very inefficient; but a crane is actually lifting heavy weights only a very small percentage of the whole time it is at work, and there is a great deal of power taken merely to keep the rope gear or shafting in motion during the whole of the time. Electricity at once sweeps away all complications and allows a perfect system. The power can be conveyed to a moving hoist without any complications; and it is needed only when work is actually being done. Where the crane is out of doors, and, as at present arranged, has a small engine and boiler of its own, the saving in first cost and in working is enormous. Mr. Sandwell mentions the case of Mr. Hermans, of Limehouse, who put in Crompton cranes, thus saving £250 a year in insurance alone, apart from the economy of working. We strongly recommend works managers to look into this matter. They will find a great deal of sound information in Mr. Sandwell's paper.

NOTES ON THE DESIGN OF MULTI-POLAR DYNAMOS.*

(*Concluded from page* 354.)

OUTPUT OF ALTERNATING CURRENT ARMATURES.

THE armature loads for alternators, though producing a cross magnetisation, as in direct-current machines, raise no considerations, of course, as regards sparking. But on account of the greater proximity of the poles, and the greater stray field resulting, it is desirable to make the layer of copper on the armature core as thin, and the air gaps as short, as possible. As a consequence, probably, of the increased ratio of stray to useful field, the induction is less in the gaps of alternating than in those of direct-current machines. Some comparisons have been made of the output of direct and alternating machines of the same weight, but these, in the nature of things, must be misleading. The two types are quite unlike in their proportions, as Figs. 1 and 2 show, and no one would think of making them the same. Fig. 1 represents the magnetic system of a four-pole direct and Fig. 2 that of a twelve-pole alternating machine of the same output; and while it will be observed that the iron parts—core and yoke-rings—are much heavier in the former, it will be noticed that the copper in the magnet coils is much heavier in the latter. In fact, though the iron in the alternator is only 55 per cent. of that in the direct-current machine, the copper required is no less than 250 per cent. It is difficult, then, to understand what useful purpose is served by comparisons such as I have alluded to.

RELATION OF AIR GAP TO DIAMETER OF ARMATURE AND NUMBER OF POLES IN DIRECT-CURRENT MACHINES.

Having established the proportionality of the volume and diameter, it is easy to find the relation which must exist between the diameter and length of air gap for any particular angle of embrace in order that sparking may not occur.

But, as is also seen from the equation, the gap required for any particular volume is proportional to the angle of embrace, and if we substitute for two poles a greater number, of correspondingly less angular width, working with an increased diameter and volume without a proportionally increased gap is made possible. This is where the advantage of the four, six, or even eight pole machine comes in.

DIMENSIONS OF THE ARMATURE.

It has been observed that the output of an armature is proportional to d^2 L; and the induction being the same, the weight of the core for a given number of poles must be proportional to the output, the radial depth increasing directly as the diameter, so that a proportionally increased field may be carried. The number of poles being fixed, the weight of the core for a given output may be taken, therefore, as approximately constant, whatever the ratio of L to d.

The power wasted in hysteresis is proportional to the weight of iron magnetised, and to the number of reversals per second. The weight being inversely, and the reversals directly, as the number of poles, the power wasted is for a given output the same.

So much for the core; let us now consider the copper part. Taking Gramme-wound armatures having an interior opening equal to ·66, or two-thirds of the core diameter, it is found—the output, speed, and temperature being predetermined—that the ratio of L to d may vary through a considerable range without making any great difference in the weight of copper or efficiency.

All the above facts go to prove that if there is anything to be gained, as regards the production of the field, by increasing the diameter of the armature and the number of poles, there is nothing, considering the armature by itself, to be lost by it. It may, in fact, be rather an advantage, because the weight of the iron core is reduced. It is true the peripheral velocity is increased; but this does not matter in the least, provided a certain limit is not exceeded. Opinions differ as to what the limit should be, some machines working at 50ft. per second, others at 100ft., and a few as high as 125ft.

DIMENSIONS OF THE FIELD MAGNETS.

It will be apparent, from the foregoing considerations, that the employment of two or more than two poles for direct-current machines of moderate dimensions resolves itself mainly into a deliberation regarding the most economical shape to give to the field magnets.

I have said that for the prevention of sparking it is necessary that, the induction per square centimetre remaining the same, the air gap increases proportionally to the diameter, whether the space is necessary for conductors and clearance or not, but that the coefficient by which the diameter has to be multiplied to

* Abstract of a paper read by Mr. W. B. Esson before the Institution of Electrical Engineers on the 9th inst.

NOTES ON THE DESIGN OF MULTIPOLAR DYNAMOS.

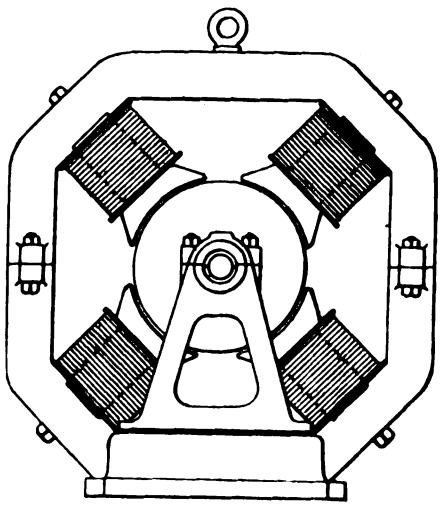

FIG. 7.

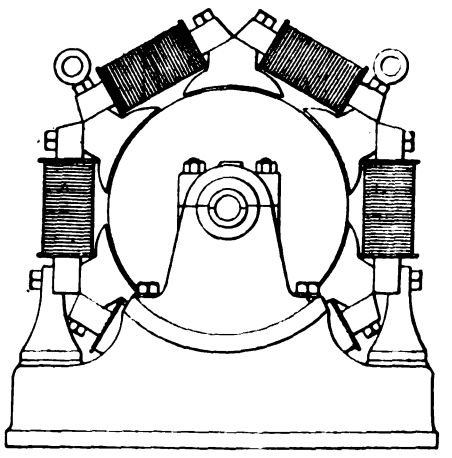

FIG. 8.

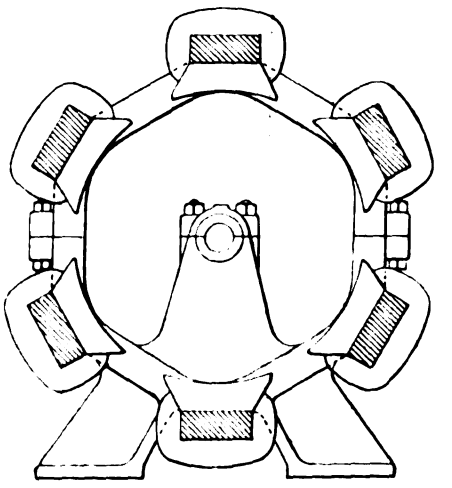

FIG. 9.

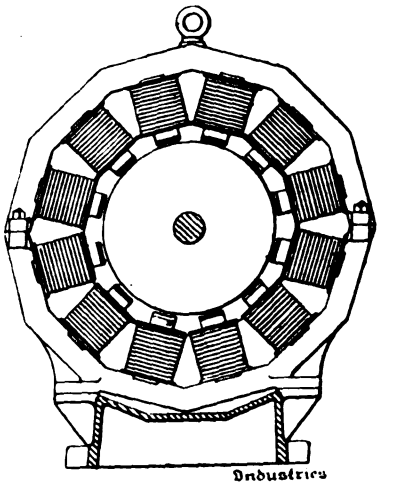

FIG. 10.

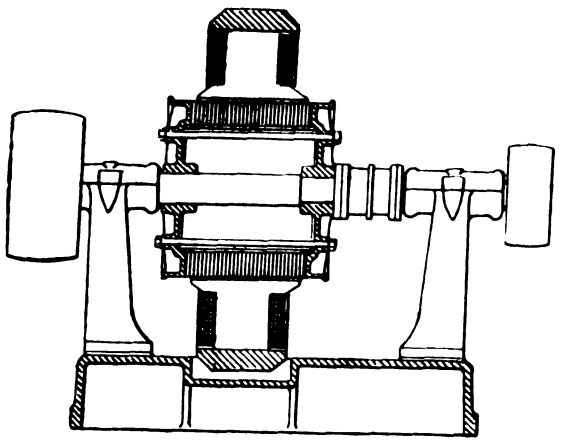

FIG. 11.

give the length of the gap necessary to prevent sparking diminishes directly as the pole angle. In comparing the magnetic system of a four or six-pole machine with that of a two-pole one, it is necessary to adopt dimensions for the armature in accordance with the considerations already mentioned; hence, if the two-pole armature had a length of core equal to one and a half times its diameter, in a four-pole one the length should be about half the diameter. The diagrams (Figs. 3 and 4) show the cross sections of two such machines. The diameter of the four-pole armature is 1·4, and its length ·5 times that of the two-pole one, consequently both machines give the same output. The weight of the two horse-shoe magnets in the four-pole machine comes to 56 per cent. of the weight of the single horse-shoe magnet, which indicates in this particular case a considerable saving in wrought iron. In taking the copper weight it is necessary to bear in mind that this does not vary simply as the length of the wire if the machines are of the same efficiency, but as the square of the length; so in this particular comparison the copper on the two horse-shoes would be, roughly, 30 per cent. more than on the single horse-shoe, assuming the length of the air gaps to be the same.

When we come to machines of a certain size there is undoubtedly a gain in employing more than two poles, while very large machines become impossible of construction with two poles only. But to go beyond four poles in many cases would be a mistake. Increasing the poles always results in an actual increase of copper, unless at the same time the power spent in the gap is reduced, and this latter must be effected without reducing the thickness of the armature winding.

Having discussed the design of multipolar machines as influenced by both theory and practice, it remains to conclude this communication by calling attention to some of the ordinary forms of multipolar fields. The double wrought iron horse-shoe (Fig. 4) is not very frequently used, being rather costly; but a similar machine with magnets of cast iron, lately made by my firm for the National Line s.s. "America," is shown in Fig. 6. This design, introduced by Gramme in 1869, generally gives place to the arrangement shown in Fig. 5, a form designed by the same inventor in 1885, and since adopted for cylinder-wound armatures by many makers, including Mr. Jaspar, in Belgium; Mr. Brown, of the Oërlikon Works, in Switzerland; and Messrs. Paterson & Cooper, in England. Fig. 7 represents a similar field in which the magnet cores are of wrought iron, fitted with cast-iron pole-pieces, as used by Mr. Kapp. The decision as to whether cast iron or wrought iron should be used is arrived at in a very simple manner—by comparing the excess of copper required on one hand with the extra machining required on the other.

All these are examples of single magnetic circuits, where the lines of force from each pole remain undivided in their paths through the magnetising coils; but in Figs. 8 and 9 are shown examples of double magnetic circuits, in which the lines from each pole take two paths through separate coils. Fig. 8 is a type of magnet used by Sautter-Lemmonier, of Paris, for Gramme-wound armatures, and by Cuenod-Sautter, of Geneva, for armatures having a Siemens winding as modified by Thury. It looks at first sight as if the weight of copper were not very different in the two types, but in this respect appearances are deceptive, for, as a matter of fact, the field of a four-pole machine made to Fig. 8 would require about 125 per cent. more copper than if made according to Fig. 7. It will be observed, however, that the magnet cores and pole pieces, which are made throughout of the softest wrought iron, are very light. In Fig. 9 the magnets are a series of wrought-iron bars lying parallel to the armature, each fitted with a cast pole-piece in the middle of its length, and having two magnetising coils, one on each side of this piece. It is a structure which may be frequently met with, though not precisely in the form shown, and the observations regarding the copper made with reference to Fig. 8 apply equally here.

The fields of alternators may be similarly divided into those having single and those having double magnetic circuits; the former requiring, as in the fields of direct-current machines, much less copper than the latter. Amongst those having single magnetic circuits are the machines of Siemens, Ferranti, Mordey, Westinghouse, Elwell-Parker, and Paterson & Cooper. Mr. Kapp possesses the distinction of having the only alternator with double magnetic circuits. The "Phœnix" alternator, shown in Figs. 10 and 11, possesses some features which may be of interest as illustrating the way in which the commercial aspect of designing has to be considered.

THE MANUFACTURE OF SOAP.

By W. Lawrence Gadd, F.I.C., F.C.S.

(*Continued from page* 355.)

IV.

After the contents of the boiling pan have remained at rest for some time (usually during the night), the supernatant spent lye is withdrawn from under the soap by means of a pipe at the bottom of the pan, and is then dealt with, in a manner to be subsequently described, for the recovery of the glycerine. As the lye is withdrawn the soap sinks down in the pan, until the escape of a small quantity from the lye pipe is the signal for shutting the tap, showing that all the lye has been drawn off and only soap remains in the pan. A little water is now poured in, and the steam turned on for the second or rosin "boil."

The rosin barrels are usually raised to the boiling house by a hydraulic or steam lift, and brought to the pan side, where they are broken open and the block of rosin smashed into small pieces, which are shovelled into the pan. At the same time, caustic lye is gradually allowed to run in until the whole of the rosin is completely saponified, and a slight taste of caustic remains in the separated lye. Salt is then thrown into the pan and the boiling continued until the soap is cut open and perfectly separated from the excess of spent lye, when the steam is shut off and the contents left to settle as before. The amount of rosin used in the manufacture of household yellow soaps varies, but usually it is about 5 cwt. to 7 cwt. to each ton of fat employed. When much oil is used, such as cocoanut, palmnut, cotton seed, or palm oils, the quantity of rosin must be reduced below that which could be safely added to a tallow soap.

After drawing off the spent lye from the rosin boil, the soap is ready for the third operation, or "boiling on strength." This consists in boiling the soap with a strong solution of caustic soda, in order to ensure the complete saponification of the fat, oil, or rosin used, and to free the soap still further from impurities which have escaped being carried away with the spent lye of the preceding operations. For this purpose it is not sufficient to add a quantity of strong lye to the soap at once, and to boil for four or five hours, as is commonly done, because the strong caustic often fails, under those conditions, to combine with small quantities of unsaponified fat, and, furthermore, the finished soap is very likely to contain an objectionable amount of free caustic soda. The grain soap should, in this operation, be first "closed," by boiling with water alone, and then the strong lye be run gradually in, until the soap is well cut open by the excess of caustic soda. The boiling is then continued for two or three hours longer, and, finally, the contents of the pan are left at rest to allow the curd soap to separate from the strongly alkaline lye.

If the object of the manufacture be a curd soap, the pan is at once covered with a lid, and felt or sacking placed upon it, to retain the heat, and it is left at rest for a length of time varying from about thirty-six hours to several days, according to the size of the pan, when the soap is either skimmed off the surface of the lye by means of ladles, or drawn off, or pumped through a pipe, which can be lowered into the soap in such manner as to remove it without disturbing the supernatant lye, whereupon it is placed in the frames to cool.

Ordinary household soap, other than curd, passes through a further operation before it is ready for running into the frames. The object of this finishing boil—technically called "fitting"—is to combine the curd soap with water, and so obtain a close homogeneous product, as well as to improve the colour.

The alkaline lye, after boiling on strength—called "half-spent lye"—is drawn out of the pan, and stored separately from the spent lye, to be used again in a first or rosin operation, or for the manufacture of brown soap; and the soap remaining in the pan is melted and boiled by means of the steam coils. Sometimes the water condensed from the steam itself is sufficient to close the soap, but generally a little water must be added. The addition of water (preferably sprinkled all over the soap as fine rain) is continued until the opaque, thick soap becomes comparatively thin, smooth, glossy, and semi-transparent, and falls at once from the trowel, in two or three large flakes. There are several signs of the soap being in the right condition, but which can only be learned by experience. On continuation of the boiling from this point, the soap expands and swells up considerably, on which the steam is shut off, the pan covered closely, and left at rest from two to five days, the exact time depending on the bulk of the charge.

At the end of that period the soap is found to have separated into three well-defined layers or strata. The uppermost one, called "fob," consists of light frothy scum, or soap impregnated with such, which varies in thickness from ½in. to 6in. or more, depending largely on the amount of water added in the "fitting" operation, and on the character of the soap. The second layer forms the bulk of the pan's contents, and is composed of the good soap, while the bottom layer consists of inferior, dark-coloured, thin soap, containing an excess of water, and technically called "nigre" or "niger." This last is left in the pan, while, after skimming off the "fob," the neat soap is drawn or pumped out and conveyed to the crutching machine, or direct to the frames, where it is allowed to cool.

Many household soaps, not made principally from oil, are what is called "run" with substances more or less detergent in character, to increase the yield, and so

Digitized by Google

cheapen the product. Among these, silicate of soda is the most important, and commonly used; but the carbonates and sulphates of soda and potash, silicate of magnesia, or French chalk, gypsum, starch, and many other materials, are also used, a large number of which must be regarded merely as so much adulteration, many being added to the soap solely with the object of increasing its weight; and with all of them a considerable proportion of water is introduced.

Silicate of soda, or soluble glass, is prepared by fusing together fine sand and soda ash in suitable furnaces, and is obtained in the form of irregular lumps of transparent glass-like material. In some soap works the solid pieces are prepared, or obtained from regular makers, and dissolved in water to form the required strength of solution. This is usually effected by placing the lumps of silicate on a perforated false bottom or tray, which is suspended in a tank of boiling water. The silicate dissolves in the water, and the heavy solution sinks through the perforated tray and is drawn out by a tap at the bottom of the tank. In the majority of soap works, however, the silicate is obtained, from regular makers, in a convenient form, as a strong solution, packed in barrels. This solution is thick and viscous, of a specific gravity, in some makes, of about 1·70° or 140° Tw.; in others, of 1·50° or 100° Tw., the former containing about 53 per cent. of solid matter. On diluting with hot water, the solution has a tendency to deposit silica on cooling, the larger quantity being deposited from the stronger solutions.

The following analysis gives the composition of a sample of thick silicate of soda solution:—

SILICATE OF SODA SOLUTION—140° Tw.

	Per Cent.
Silica	34·29
Soda (Na_2O)	18·01
Sulphate of soda	·29
Sodium chloride	·37
Carbon dioxide	·17
Oxide of iron and alumina	·27
Water	46·60
	100·00

For running the soap, the thick solution of silicate is diluted with boiling water, in suitable tanks provided with steam coils, to the requisite strength, which varies very greatly for different soaps, and according to the proportion of solution added to them.

(To be continued.)

THE "DONALD" PROCESS FOR THE MANUFACTURE OF CHLORINE.

RUMOURS of new processes which were to revolutionise the business of the chlorine manufactories have from time to time awakened the interest of those concerned in the chemical industries, and, at the present time, when nitrate is so cheap, nitric acid is apparently a more economical oxidising agent than manganese, which has hitherto almost universally been employed.

The "Donald" process is the same as that by Weldon in the first and last stages—viz., the saltcake furnace and the bleach chambers. It is in the second stage, and in dealing with the hydrochloric acid in the gaseous state, that the Donald process seeks to effect improvements, combining economy with efficiency. The hydrochloric acid gas as it issues from the saltcake furnace is not liquefied as in the Weldon process, but is conveyed in a gaseous state through a series of tanks containing nitric acid, by which the chlorine (the whole of it) is eliminated, and passes on pure and dry direct to the bleach chambers. There is, therefore, practically no loss of chlorine, and consequently, for the present make of bleaching powder, less than one-third of the present consumption of raw material will be required. The acids employed are not deteriorated by use, and can be used over and over again with only a small percentage of loss. The plant required is simple and inexpensive, and, the action of the nitric acid being speedy and direct, the process may be arranged to give a continuous yield. The Donald process has been favourably reported on by Professor Mills, and has likewise been examined and commended by Messrs. Tatlock, Garman, and Rawan. Estimates have been made of the cost of working the new process, which, after ample allowance for all necessary expenditure and a wide margin for contingencies, indicate a substantial return on the outlay. A limited company was accordingly started in Glasgow at the close of last year to carry out the new process. Works will be built forthwith capable of manufacturing 100 tons of bleaching powder weekly, the plans being so arranged that a portion of the buildings and plant will first be erected without expending more than half the estimated cost of the works, ample provision being made for extension when required.

Notes.

EXHIBITION AT RHODE ISLAND, U.S.A.

THE movement to open in Providence an exposition of Rhode Island products seems at last in a fair way to assume definite form, as steps have been taken by energetic business men to awaken general interest. There has never been anything of the kind in Rhode Island, and yet it is one of the leading manufacturing communities of the United States. It has been suggested to have as one feature an exhibition of all the processes of manufacture, from the raw state to the finished product. Some of the processes of worsted, iron, steel, rubber, leather, and jewellery manufacture could be shown in this manner, and would make the Exhibition a powerful educational influence, as well as a success financially.

PORT MELBOURNE DRAINAGE.

ALTHOUGH the plant is not yet complete, a trial of the Port Melbourne drainage pumping scheme has been made with satisfactory results. The machinery includes five engines, working powerful centrifugal pumps, two of the sets being equal to a discharge of 2,600 gallons per minute, while the other three can work up to 5,500 gallons. The sewerage is collected, states the *Australasian Builder*, at the pumps by a large sewer and lifted into an outlet sewer which discharges it into the bay. During the trial of one of the smaller sets, a quantity of between 30,000 and 40,000 gallons was put through in a quarter of an hour, and it is calculated that the capacity of the whole plant will more than deal with the drainage of Port Melbourne.

RAILWAYS IN GREECE.

THE contract for the Piræus-Larissa Railway, given out in July, 1889, allowed of a period of twelve months for the preparation of the necessary plans. Owing, however, to the French engineers attached to the Greek Government insisting upon a deviation from the route originally fixed upon, the period was found too short for a line, which, with the Chalchis and Lamia branches, is 390 kilometres in length. The line starts from the Piræus, where it will be in direct communication with the harbour and with the vessels lying along the quay close to the railway siding; passes through Athens, Boyáti, Thebes, Livadia, Dádi Scarmitza, Ofana to Larissa. The branch from Chalchis joins the main line 30 kilometres south of Thebes, and that from Lamia at Liano Kládhi. The rails and locomotives are being supplied from England, but the carriages are being built in Belgium.

A NEW DOCK AT BOMBAY.

THE new graving dock constructed by the Bombay Port Trust, and called the Merewether Dock, was opened last month by Lord Harris. The dock, which communicates directly with Prince's Dock, was to have been completed within two years from the commencement, but the work has been done in far less time. It measures 500ft. on the floor, but the length available for docking is 530ft. The width at the coping is 90ft., and on the floor 62ft. The depth at the head is 33ft., at the stern 34ft., and the available depth of water for docking at high water of spring tides is 28ft. 7in. A sill at the entrance has been determined on at an extra low level to accommodate ships of the Royal Navy up to the second class. The dock is fitted with three 36in. centrifugal pumps, capable of pumping 60,000 gallons per minute, so that the dock can be pumped dry in three hours. The average number of men employed in the construction was 2,000.

A NEW LIQUID FUEL GAS PROCESS.

AT the gasworks of Saratoga, U.S.A., a plant has recently been erected by Mr. Andrews for the manufacture of gas from liquid fuel. By the Andrews process the oil (crude or Lima being used) is heated in two superheaters in each bench, which subject it to great heat and gasify it previous to its introduction to the pipe retorts, thus obviating the deposition of graphite in them and preventing the possibility of their clogging, at the same time steam is superheated to about 1,700 degrees before it reaches the retorts. The retorts, states the *American Manufacturer*, consist of double pipes, the outer one of cast iron and the inner one of copper. Notwithstanding the fact that both oil and steam have practically been converted into the gaseous form before they reach the retorts, they are not permitted to mingle until they have travelled several times to and fro on the bench, when the inner pipe terminates and the two gases mingle. A fixed hydrocarbon gas is the result, which may be piped any distance, and when subjected to the greatest cold shows no condensation. The gas has great heating properties, and is a splendid illuminant, being used in the town of Saratoga for both lighting and heating. The gas has also been applied to a furnace specially built for heating and melting iron, in which connection it has given the most satisfactory results. Iron, steel, and copper have been heated and melted in remarkably quick time, the flame produced being mellow, but intensely hot. The illuminating gas is of 28 candle-power, and requires no purification after it leaves the retorts.

BORING WITH POWER DRILLS AT THE ST. ANDREASBERG MINES.

AT the St. Andreasberg silver mines in the Harz, rock drills worked by compressed air have recently been introduced. The air compressor is placed underground, and is driven by a Girard turbine. The special point of interest in connection with this installation is the regulator, which consists of an air reservoir hewn in the solid rock. By the employment of power drills, it is found that in driving levels there is a saving in cost of 58·2 per cent., whilst 4·04 times as much work is done as that accomplished by manual labour. The cost of stoping by hand was 16s. as compared with 8s. 6d. by machine per cubic metre of ore won. In the case of shaft sinking, the cost with machine, inclusive of explosives, was £4 per running metre, as compared with £7 10s. with manual labour.

A NEW MINERAL.

MR. H. A. MIERS, in the *Mineralogical Magazine*, describes a new mineral, which has been named "Sanguinite." It was observed on specimens of argentine from Chañarcillo, and is probably a hexagonal sulpharsenite silver, allied to proustite. To the naked eye the mineral appeared to be göthite, but examination with the microscope revealed its different character. It has lustre, like earthy hematite; colour, bronze-red by reflected light, and blood-red by transmitted light; streak, dark, purplish brown. No quantitative examination was made, on account of the small quantity of material; a qualitative analysis, however, showed the presence of silver, arsenic, and sulphur. The physical characters, as a whole, prevent the mineral from being referred to proustite or xanthoconite, the mineral being nearer like the former in its physical characters. The specific gravity and hardness have not been determined.

IRON AND HARDWARE IN AUSTRALIA.

THE total value, expressed in dollars, of iron and iron manufactures imported by Australia is over $30,000,000 per annum. Nearly all these imports are admitted free into New South Wales. Rich deposits of iron ores are diffused throughout that colony, but are almost wholly neglected. There are many iron foundries in the colony engaged in the manufacture of steam engines, railway material, and agricultural implements, for which material is imported. The great bulk of the iron imports comes from Great Britain. The value of iron and steel imported by New South Wales during 1889, excluding machinery and hardware, was $2,138,278, the leading items being:—Pig iron, $147,270; iron and steel pipes, $596,555; other castings, $65,975; bar, rod, plates, and sheet iron, $706,485 bolts, nuts, rivets, and screws, $102,630; other wrought iron, $401,345; iron and steel tanks, $67,945; safes and doors, $70,220; wire, $512,785; galvanised manufactures, $363,930; wire netting, $15,735. The value of hardware imported by New South Wales in 1889 was $2,382,205, against $2,142,290 for the preceding year. Great Britain shipped direct to the value of $1,82,005, besides a considerable quantity by way of Victoria. The United States furnished, direct, hardware valued at $396,980. There were 350 establishments in New South Wales, states *Hardware*, during 1889 engaged in various kinds of iron-work, giving employment to between 8,000 and 9,000 hands, with a larger number of establishments and hands in the colony of Victoria, where more attention is paid to manufactures of all kinds than in New South Wales.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

31st March, 1891.

5506. Weston, G. H. ..... Rotary engines.
5511. Brierley, W. ..... Carding engines (*Moog*).
5517. O'Connor, P. ..... Pipe couplings.
5520. Phillips, S. G. ..... Apparatus for drying bricks.
5522. Hollingworth, L. ..... Cloth guiding machines.
5524. Reeves, Stamp, & Houghton ..... Jacquard machines.
5527. Mallaband, T. H. ..... Melting furnaces.
5528. Tomlinson, J. D. ..... Flyers for spinning and twisting asbestos yarn.
5529. Sawrey & Collet..... Apparatus for separating liquids from solid matters.
5534. Grove, J. ..... Shaft couplings.
5535. Grove, J. ..... Couplings for shafts.
5536. Blakeney, W. H. ..... Pneumatic tube conveying apparatus.
5537. Thompson, W. B. ..... Fly wheels for motors.
5538. Blakeney, W. H ..... Water cock or valve.
5540. Hogg, Bowie, & Prentice ..... Steam boilers.
5543. Klatte, O. ..... Permanent way of railways.
5549. Whittaker, W. ..... Railway signalling apparatus.
5553. Pape & Henneberg ..... Centrifugal sorting machines.
5555. Haddan, R. ..... Evaporators (*Evans*).
5561. Gehre, M. ..... Apparatus for determining the quantity of liquid in steam.
5564. Thompson, W. P. ..... Shaft couplings (*Gaveron*).
5567. Lardeur, A. E. ..... Mitreing machines.
5568. Skinner & Connolly ... Looms.
5569. Rapieff, J. ..... Pneumatic ordnance.
5575. Donnelly & The Patent Stamped Steel Railway Axle Box Company, Ld. ..... Axle boxes.
5578. Clinton, McNamara, McIntire, Smith, & Livermore ..... Typewriting machines.
5581. Edwards, E. ..... Pumps (*Roessler*).
5587. Naylor, W. ..... Railway vehicle couplings.
5589. Smyser, H. E..... Weighing, package making, and filling machinery.
5593. Lake, H. H..... Projectiles (*Roth*).
5594. Lake, H. H..... Pipe couplings (*Linzee, Jun.*).
5597. Selkirk, A..... Apparatus for disintegrating fibrous materials.

1st April, 1891.

5600. Hart, G. W..... Steam boilers.
5601. Ormerod, Crook, & Galloway ..... Looms.
5607. Higgins, C. P. ..... Riveting machines.
5612. Hook, G. ..... Folding machines.
5614. Pratt, C. T. ..... Drill chucks.
5618. Wrigley, M. H..... Rotary engines.
5620. Kirby, J..... Fluid pressure engines.
5621. Lockwood & Storey ... Looms.
5625. Davey, H. ..... Steam boiler feed apparatus.
5628. Woodhouse, J. H..... Drilling machines.
5631. Blakeney, W. H. ..... Engines and pumping apparatus.
5640. Griffiths, W. B. ..... Bottle washing machines.
5645. Munns, W. H. ..... Automatic car brake and brake governor (*Kellog*).
5649. Munns, W. H. ..... Pumps (*Frost*).
5654. Walsworth, J. B..... Apparatus for clearing, lowering, and disengaging ships' boats.
5658. Moncrieff, R. W..... Jacquard design, reading, and card punching machines.
5659. John Brinton & Co., Ld., Bedford, & Pearse... Machinery for the manufacture of chenille or chenille fur.
5660. Jacométy & Lenicque... Apparatus for treating ores.
5663. Fachris, J. B..... Motive power engine.

2nd April, 1891.

5668. Rose, B..... Manufacture of metallic tubes.
5672. Mann, Smith, & Read... Differential speed gearing.
5674. Roots, J. ..... Gas engines.
5677. Holt, J. ..... Looms.
5697. Schmidt, W. ..... Apparatus for superheating steam.
5701. Ketchum, O. W..... Gas producers.
5705. Warrington & Warrington ..... Puddling furnaces.
5710. Mills, C. K. ..... Tubing steam boilers and tools therefor (*Caraman Vassel & Cie.*).
5711. Thame, J. R. ..... Manufacture of seamless tubes or conduits.
5724. Schwörer, E..... Apparatus for superheating steam.

3rd April, 1891.

5728. Brindle, Reade, & Taylor ..... Apparatus for washing, bleaching, dyeing, and drying yarn in the cop.
5730. Watmough, T. ..... Steam boiler furnaces.
5738. Newton, C. B. ..... Differential pump gearing.
5739. Benyon, G. W. ..... Interlocking railway signals, points, and block telegraph instruments.
5742. Judson, Longbottom, & Hudson ..... Steam engine valve gear.
5747. Skene, R..... Gas engine governor.
5757. Fairbrother & Damon Machine for bending wire wall ties.
5768. Stuart, C. ..... Air compressors.
5772. Huelser, C..... Clay presses for making tiles (*Fröhlich, Sen.*).
5775. Johnston, D. ..... Water heaters.
5776. Hagaus, C. ..... Locomotives.
5783. Mudd, T..... Apparatus for superheating steam.

4th April, 1891.

5793. Holgate, J..... Looms.
5796. Williams & Morris..... Machinery for cleaning tin or terne plates.
5798. Bersin, N. ..... Axle and shaft bearings.
5808. Wotherspoon & A. & J. Stewart & Clydesdale, Ld..... Machines for the manufacture of tubes.
5814. Oldfield, T. ..... Lathe beds.
5817. Earsdon, Day, & Day... Lathes.
5820. Morton, A. ..... Steam engines.
5826. Taylor, G. H. ..... Manufacture of chains and machinery therefor.
5848. Rauser, Wieber, & Sokoloff ..... Apparatus for automatically controlling the supply of water to steam boilers.

ELECTRICITY.

31st March, 1891.

5508. Hemming, T. L. ..... Method of electro-plating wire.
5518. Ayrton & Ayrton ..... Electric meters.
5539. Stuart, F. E..... Street fire alarms and their combination with telephones.
5547. Kellner, C..... Apparatus for electrolytic decomposition.
5548. Bishop, J. D. ..... Electric conductors.
5580. McEvoy, C. A. ..... Circuit closers for torpedoes and submarine mining apparatus.
5595. Dewey, M. W. ..... Electric heating apparatus.

1st April, 1891.

5617. McGeoch, Jun., & McGeoch ..... Electrical meters.
5637. Barker, R. W. ..... Converters (*Farmer*).
5638. Crowdus, W. A. ..... Batteries. (7th October, 1890.)
5641. Angold, A. E. ..... Arc lamps.

2nd April, 1891.

5679. Strenberg, R. ..... Telephones.
5690. Bull, H. C..... Batteries.
5712-13-14-15. Pitt, S. ..... Insulating electrical conductors (*Davidson*).

3rd April, 1891.

5766. Philpott & Hammond... Apparatus for use as a current meter or as a motor.
5780. McMahan, J. M. ..... Cut-out for electric circuits.
5790. Boehm & Bailey ..... Incandescent lamps.

4th April, 1891.

5802. McGeoch, Jun., & McGeoch ..... Incandescent lamps.
5824. Pitkin, J..... Filaments for incandescent lamps.
5834. Wilkinson, G. ..... Measuring instruments.
5835 Jones, A. D. ..... Measuring or indicating instruments.

CHEMISTRY.

31st March, 1891.

5519. Beylikgy, Everett, & Collins ..... Alkalino-magnesian silicate compound.

3rd April, 1891.

5748. Moss & Newton..... Production of carbonic acid gas.
5777. Bruce, W. T. ..... Manufacture of sulphuric acid and apparatus therefor.
5788. Feld, W. ..... Manufacture of sodium and potassium carbonates, sulphur, and sulphuric acid.

4th April, 1891.

5821. Curtis & André ..... Explosives.

MISCELLANEOUS.

31st March, 1891.

5513. Fenton & Fenton..... Joining woven and other machine bands.
5551. Tresidder, T. J. ..... Armour plates.
5574. Haire & Turner ..... Wrenches.

1st April, 1891.

5623. Thompson, W. P. ..... Packing rings for flange joints (*Schonleber & Knauss*).
5629. Lucas, Lucas, & Bishop Adjustable spanners.
5642. Sowerby & Casper ..... Casting metals.

3rd April, 1891.

5749. Johnson, J..... Refractory linings for furnaces (*Blair, Jun.*).

4th April, 1891.

5828. Poole, W. H. ..... Metallic packings for piston rods, &c.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1890.

8267. Marsden.
4999. Bayley & Cooper.
5100. Morfitt.
5239. Blum.
5330. Anderson.
5733. Imray (*Hogan Engineering Company*).
6502. Lake (*Swift*).
6647. Hawes.
6749. Cochrane.
6840. Rigby.
7253. Hodge.
7264. Stones & Stones.
7564. Bachmann & Pieper.
7666. Thorne.
7846. Byers.
7901. Hoffmann.
7984. Cooke.
8038. Kelly.
8212. Muir.
8290. Mills.
8337. Simon.
8368. Price.
8418. Barnes.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

CRUSHING AND GRINDING MACHINES.—*M. H. Simonet, Quintin (Cotes-du-Nord), France.*—The machine embraced by this invention is constructed as follows:—A double cylindrical casing has journaled in each end of it the spindles of two cylinders which revolve inside the casing, and have formed on their periphery helical projecting ribs, the number of which increase towards the delivery end of the machine. Inside the double cylindrical casing are arranged two cylindrical shells concentrically with the revolving cylinders, and provided on their inner surfaces with concentric projecting ribs. At the point of intersection of the double casing containing the cylinders is a groove, which contains a longitudinal adjustable blade forming a knife, which bears against the whole length of the two cylinders, and cuts the substance introduced into the machine. Claims: (1) A crushing, grinding, or mixing machine, comprising a double cylindrical box or case provided with two movable adjustable shells having ribs on their inner sides for crushing or grinding the material in connection with two cylinders, also provided with ribs; (2) in a machine as above claimed the use of a longitudinal knife or blade for cutting and separating the substance drawn through the cylinders; (3) the machine substantially as described.—No. 4153. March 17th, 1890. 6*d*.

CAR COUPLINGS.—*A. C. McCord, Minneapolis, Minnesota, U.S.A.*—Fig. 1 in the annexed illustrations is a perspective view of a car coupling embraced by the invention, Fig. 2 is a sectional plan, and Fig. 3 shows the swinging jaw. Pivoted in two projecting arms of the main body A formed with an inclined face, as shown, is the swinging jaw B, in the front part of which is pivoted the locking pin actuating plate C, the front end of which projects slightly beyond the end of B. The jaw B is provided with two arms B^1 (Fig. 3) adapted to slide respectively under and over a projecting tongue (Fig. 2) in the slot in A. Pivoted at E in the upper arm of B is the locking bolt F, the lower end of which is connected to the inner end of C, and is arranged to swing in a slot in the second arm of B. A tail on B limits the outward

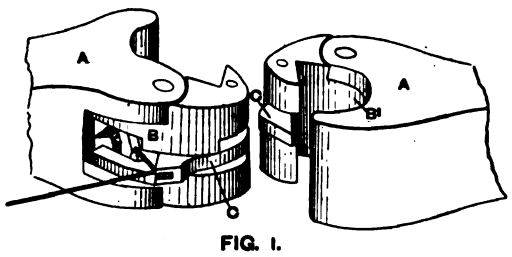

FIG. 1.

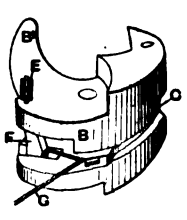

FIG. 3.

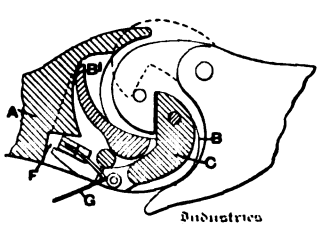

FIG. 2.

swing of the latter. It will thus be seen that when the jaws are brought together into the coupling position, they will be locked by the bolt F, owing to its tendency to regain the vertical position, swinging forward and locking the swing jaws. When, however, one or both of the swing jaws is already locked, they will be released to allow of their being brought into the coupling position by the forward end of C being struck by the opposite jaw, so drawing F out of engagement with D. A rod G connected to C allows of the unlocking of the jaws from the side of the car. Nine claims are made.—No. 18373. November 4th, 1890. 8*d*.

BRICK MOULDS.—*E. Cammiss, Cowpen, Bewley, Durham.*—The invention embraces a method of forming the interior of the dies so as to avoid roughened edges of the bricks pressed, and to ensure a more perfect lubrication thereof. The die is made with a casing of wood, and is lined inside with narrow strips of metal secured to the casing only along their upper edges. These strips are arranged to overlap each other, so that the lubricant used may ooze out from behind them. A series of conduits are formed behind these strips in the casing to allow of the passage of the lubricant, said recesses or conduits being connected with a feed hole in one side of the mould. The die is constructed with tapered side and ends, the opening next the machine, which is constructed with its corners rounded, being of greater dimensions than that of the opening at the finishing side, which is constructed to form a true rectangle. Claim: In moulds or dies to be used in the manufacture of bricks the general construction and arrangement of parts for facilitating the moulding of the clay with smooth surfaces and sharp clean edges, and consisting of the internal shape or configuration of the mould combined with the means employed for lubricating the clay as described.—No. 3798. March 11th, 1890. 8*d*.

STEAM BOILER FURNACES.—*W. H. Wilson & J. Welsh, both of Hayfield, Derby.*—The invention embraces an arrangement for using oil or hydrocarbon fluids in connection with a coal fire. The oil is conveyed from a tank placed at a higher level than the boiler by a pipe into a chamber of brass. This chamber is in the form of a bulb on a steam pipe connected to the boiler, and leading to a number of perforated pipes placed above the coal fire in the furnace; the lower end of the oil pipe enters the steam pipe in the form of a nozzle just below the bulb or chamber, so that the steam acts as an injector, so carrying the oil with it through the perforations in the pipes into the furnace. Claims: The improved apparatus for burning oils or other hydrocarbon fluid in connection with a coal fire, by the combination of an oil supply pipe and a steam jet with branch pipes, and a curved perforated distributing pipe, substantially as described.—No. 5117. April 2nd, 1890. 8*d*.

APPARATUS FOR GRINDING CARDING ENGINE FLATS.—*S. H. Brooks, West Gorton, & J. Edge, Gorton, Manchester.*—The invention embraces improvements in apparatus for grinding revolving flats of carding engines without removing them. In the accompanying illustrations Fig. 2 is a side elevation of part of the bend of a carding engine and grinding bracket and roller with the apparatus embraced by the invention affixed thereto, and Fig. 1 is a front elevation of same with the "bend" in section. The

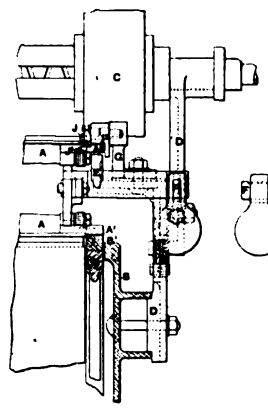

FIG. 1.

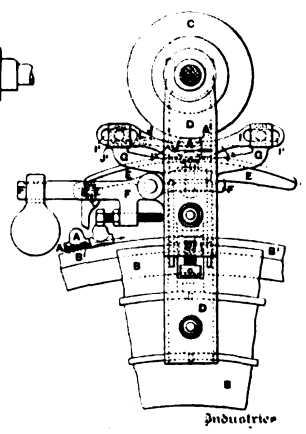

FIG. 2.

flats A, the bend B, the flexible bend B^1, the grinding roller C, the grinding bracket D, the horned bracket E, over which the flats travel, and the pivoted and weighted lever F, which successively lifts up each flat while being ground, may be of any ordinary construction. Fixed to D is a bracket G, which supports the grinding block I by means of two pins H carrying anti-friction rollers in the former, projecting into slot I^1 in the latter, said slots being inclined to a degree equivalent to the amount of "heel" required upon the flats. A planed surface I^2 is provided on the underside of I, against which the working surface A^1 of A is brought to bear as it is raised by F. On one side of I is pivoted a tumbler J, against the end of which the flat strikes as it is moved forward, so causing the flat and block I to move forward together until the bevelled end J^1 of J is sufficiently depressed by the stud H to release the flat, when I is forced back to its normal position by gravity or by means of a spring or weight. Claims: (1) An apparatus for grinding the revolving flats of carding engines when *in situ*, having a sliding grinding block, against which the working surface of the flat rests, and which on studs or slides moves along and carries the flat along a path inclined to the radius of the grinding roller, as described; (2) a sliding grinding block, against which the working surface of the flat rests, having inclined slots or inclined ends, which as it moves forward give the required inclination to the flat, as described; (3) the combination with a grinding roller C, grinding bracket D, horned bracket E, and pivoted lever F, each of ordinary construction, of the fixed and stationary bracket G and the sliding grinding block or bracket I, constructed as shown.—No. 4081. March 15th, 1890. 11*d*.

STEAM ENGINE REVERSING GEAR.—*D. A. Frazer & G. W. Cosford, both of Mancelona, Michigan State, U.S.A.*—In the annexed illustrations Fig. 1 is a longitudinal vertical section, Fig. 2 a sectional plan, and Fig. 3 a transverse section on line X X of Fig. 2 of a double-acting engine with the reversing gear embraced by this invention applied thereto. Beneath the steam chest A is placed a rotary valve B (Fig. 4) having an annular exhaust

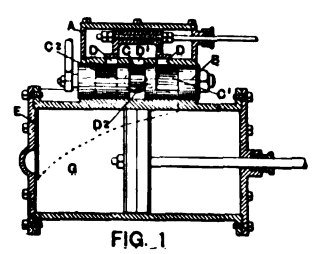

FIG. 1

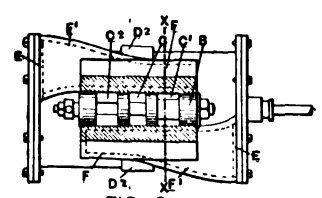

FIG. 2

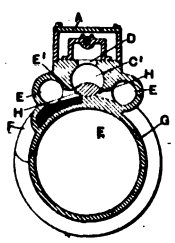

FIG. 3

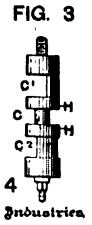

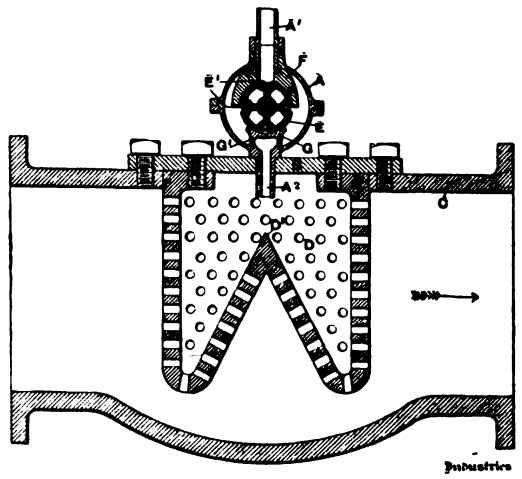

FIG. 4

passage C beneath and connecting the exhaust port D^1 with the exhaust pipe D^2. The openings C^1 C^2 serve to connect the live steam ports D with ports E^1 at each side of said passages which open into the chambers E. The latter are extended in opposite directions as shown at F F^1, and communicate with the respective ends of the cylinder G. H are air vents consisting of channels between the live steam and exhaust ports; these channels are cut part way in the valve chamber and the remainder in the valve, and are connected and open when in line, which occurs when all ports E are cut off. The operation of the device is as follows:—Live steam is alternately admitted to the ports D, and exhausted through D^1 in the usual manner. If, now, the upper side of the valve B is turned to the right, steam passing into C^1 will pass into the right hand chamber E, and thence into the forward end of G, and steam passing into C^2 will pass through the opening in the bottom into the left hand chamber E, and thence into the rear of G, and the engine will run in one direction. If, however, the upper side of the valve B be turned to the left, the steam will now pass in the opposite direction, the steam from G^1 passing into the left hand chamber E and to the rear end of G, and the steam from C^2 into the right hand chamber E and into the forward end of the cylinder G, thus causing the engine to run in the opposite direction; by turning the valve B toward the middle position the steam will be throttled and the air vents opened. Three claims are made.—No. 1436. January 27th, 1891. 6*d*.

METAL PRESSES.—*G. T. Aston, W. H. Aston, & C. T. Aston, all of London.*—The invention relates to presses in which the stamping die is actuated by an eccentric or crank and a connecting rod. For facilitating the adjustment of the stamping die the bearings of the crank shaft are fixed in eccentrics at each side working round in the solid framing. The eccentrics have each a projecting lever, by which they can be turned in the framing. These levers are connected by a cross-bar, in which is a swivelling nut. A screw, on which is a hand-wheel, runs in this nut, being attached to the framing below in a swivelling centre. Thus, by rotating the screw, the whole crank shaft may be raised or lowered. The clutch for governing the motion of the crank shaft is made with two horns opposite to each other, but working in exterior and interior circles. They can, therefore, only fall into gear when both are opposite their own catches, so that the strain is on both sides of this shaft. The treadle for actuating the clutch does not act directly upon it, but on a bell-crank lever through an intermediate shaft carrying two discs. From one of these discs proceeds a rod connected to the treadle, whilst from the second disc proceeds a second rod, connected to one arm of a second bell-crank lever, a projection on the other arm of which enters a hole in one arm of the first-mentioned bell-crank lever, and the other end of which actuates the clutch. Five claims are made.—No. 4516. March 22nd, 1890. 8*d*.

LUBRICATORS.—*F. Williamson, Tilbury, Essex.*—Referring to the annexed illustration, which is a vertical section of the improved lubricator applied to the steam pipe of a locomotive or other engine, the spherical box A is furnished with a supply pipe A^1 and a delivery pipe A^2, the pipe A^1 being connected to any suitable oil reservoir, while the pipe A^2 is screwed through

Industries

the plate B bolted to the pipe C and to the flanges of the perforated casing D having the shape shown in the figure, and the edges of which are raised inwardly to form a cone, the apex D^1 of which is in a line with the axis of the pipe A^2. The pipe C is inserted between two sections of the steam pipe of an engine in front of the stop valve. Journaled in A is the spindle of a disc E, one end of which spindle passes through A and is connected with suitable actuating mechanism (not shown). The disc E, which has formed in it recesses E^1, adjustable in size by means of screws, the heads of which form the bottoms of said recesses, revolves between bearings F G, the latter of which is made resilient by means of springs G^1. It will thus be seen that, as E revolves, the recesses will be filled with oil, which is then delivered to the interior of A, passes through A^2, and, falling on the apex D^1, is divided into a number of minute particles dashed into D, through which they are carried by the incoming steam to the parts to be lubricated. A modification of the lubricator as applied to marine engines is also described. In three claims the inventor includes the lubricator as described, together with modifications.—No. 6593. April 29th, 1890. 8*d*.

SLIDE VALVES.—*J. Marshall & R. Wigram, both of Leeds.*—The invention relates to expansion valves working in connection with main valves, and used in controlling the inlet and outlet of steam to and from the cylinders of any engine, the object being to relieve said main and expansion valve from friction caused by steam pressure. For this purpose the main valve is made of a box section. The steam ports on the back of the valve are made at right angles to, or at any angle relative to, the centre line of the spindle. The expansion valve is also of a box section. The steam ports of this valve are formed in one face only of the box. The balance or relief of this valve is obtained by admitting the steam used in working the engine through the valve between two larger faces either through the ends or sides of the box. The steam-chest cover has its inner base grooved, and into this groove is received a packing capable of adjustment. The inner face of the packing bears upon the back of the expansion valve. The space enclosed between the slide valve steam-chest cover and the packing is connected either with the condenser or receiver of the engine or with the atmosphere, to relieve the pressure on the back of the valve. Two claims are made embracing the construction of slide valve substantially as described.—No. 7141. May 7th, 1890. 8*d*.

Digitized by Google

SHAPING MACHINES.—*H. Greenwood, Leeds.*—The machine embraced by this invention is especially designed for the purpose of shaping the teeth of bevel and spur wheels. Referring to the annexed illustrations, Fig. 1 is a plan, Fig. 2 a side elevation, and Figs. 3 and 4 views of details of the actuating mechanism for the automatic feed motion of a machine constructed on the principle of this invention. Sliding on a slide on the bed-plate A about a pivot B is a segmental plate C, shown partially in dotted lines (Fig. 2), on which is carried the work to be operated upon and the dividing mechanism. On the surface of C is fixed bracket D and an adjustable bracket D^1, operated from screw D^2. These brackets carry the shaft

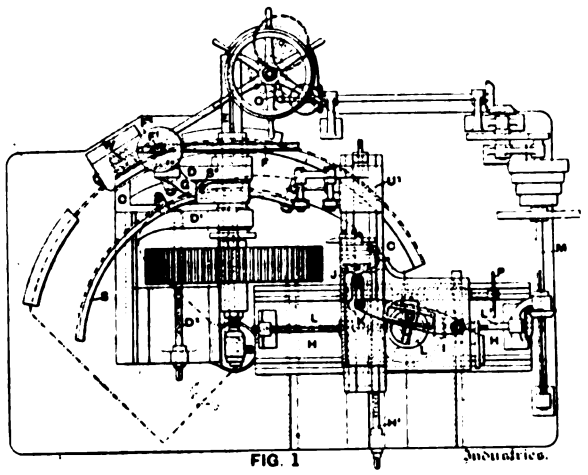

FIG. 1

E, on which is a dividing wheel F gearing with a worm on a shaft F^1, a spring arm on which is arranged to revolve over the surface of a dividing plate F^2. The shaft F^1 and plate F^2 are carried in a bracket G arranged to move in a vertical plane on a sleeve on shaft E capable of sliding and revolving therewith. One end of the spindle carrying the wheel to be operated upon is fixed to the end of E, the other end being pivoted at the axis of rotation of C. Moving in a slideway in A is a slide H, adjustable from screw H^1, on the face of which is a second slide I, adjustable at right angles to H, and on the slide moves the tool-holder J, which receives a reciprocating motion from a rocking lever K operated by eccentric L receiving its motion, by means of suitable bevel gearing and shaft L^1 from the driving shaft M. The feed of the tool towards the axis of the wheel to be operated upon is effected as follows, reference being made to Fig. 4. The actuating screw of slide I carries a ratchet wheel N, which is revolved by means of a pawl on a lever O actuated as shown from shaft L^1. A gear wheel (not shown) also on L^1 gears with a wheel P, a stop on which, when the tool has been advanced to the root of the tooth being shaped, strikes a catch Q, so allowing a spring to actuate a bell crank lever R, one arm of which then strikes a pin on the pawl on O, so disengaging it. The slide I is then moved back to its starting position by hand and the operation repeated. To cause the tool to follow the shape of the teeth being shaped, the wheel being operated on is rocked by the following mechanism:—Supported by and sliding in bracket G is a segmental rock bar S, operated by a pinion S^1 on the end of which is carried a "former" T (Fig. 2), of a shape similar to that of the teeth being shaped. This "former" is arranged to be pressed on to two contact pieces U U^1 (Fig. 3) carried by a bracket U^2 adjustable on slide of face I. Fixed to the end of S is a cord V carrying a suitable weight. When said cord is placed over pulleys, as shown, it causes T to press on the contact piece U, but if in the position shown by dotted lines (Fig. 2), T

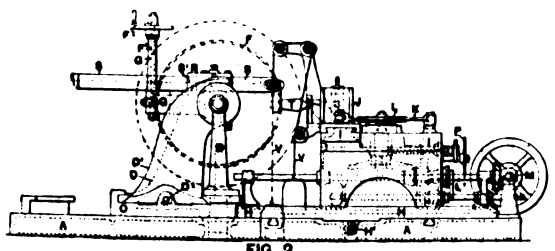

FIG. 2

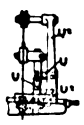

FIG. 3

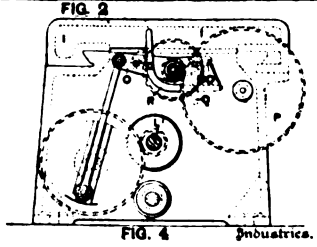

FIG. 4

will be pressed on U^1. It will thus be seen that as the tool and slide I is advanced the shaft E, and consequently the wheel, being operated upon will be rocked according to the shape of T. The above-described feed motion is used only when the teeth of spur wheels are being shaped. When, however, bevel wheels are shaped the work is fed to the tool by means of a worm W engaging rack teeth on the circumferential edge of C, the said worm being operated from shaft M by means of an automatic feed motion similar in all respects to that applied to slide I and suitable intermediate gearing. Claims: The arrangement of machinery above described for shaping the teeth of bevel and spur wheels, wherein an automatic feed and stop motion is provided for bringing the traversing tool to the work, or the work to the traversing tool, and arresting the action of the machine, and wherein also the axial motion of the work is controlled (independently of the dividing wheel control) by means of a "former" or "copy," for the purpose of giving the requisite profile form to the teeth.—No. 6669. April 30th, 1890. 1*s.* 1*d.*

WATER GAUGES FOR STEAM BOILERS.—*J. Dewrance & G. H. Wall, London.*—The invention embraces the use of a ball valve in the top arm of a water gauge to prevent the rush of steam should the gauge glass break. The valve is contained in a chamber connected to the screw plug which closes the opening through which the glass is introduced. The upper part of this valve box fits into a diaphragm formed in the body of the water gauge, and between the valve box and the end of the screw of the plug there are suitable openings for the passage of the steam to the valve box. The passage for the steam from the boiler is above the diaphragm and above the top of the valve box. Underneath the diaphragm is a circular cavity larger and deeper than the valve box communicating with the glass, and there is a hole in the side of the valve box below the diaphragm for the passage of the steam to the glass. The floor of the valve box is inclined so that the ball normally rests at the opposite side away from the hole in the side thereof. The ball is, however, forced against the hole in the side of the valve chamber when the rush of steam increases. Claims: The improved apparatus and arrangements whereby an automatic valve is put into and taken out of the top arm of a water gauge.—No. 4924. March 29th, 1890. 6*d.*

MULTITUBULAR BOILERS.—*P. E. J. & G. A. L. Niclausse, both of Paris, France.*—The invention has for its object a multitubular steam generator, the tubes of which can be separately removed, and are in equilibrium. In the annexed illustrations Fig. 1 is a

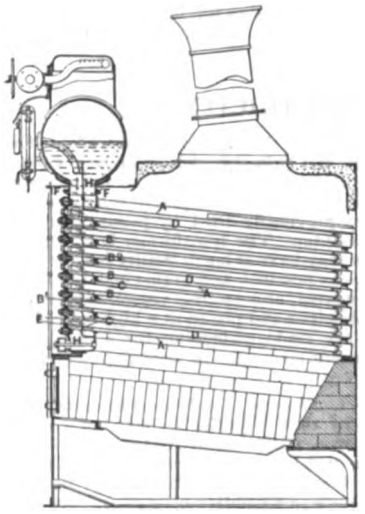

FIG. 1

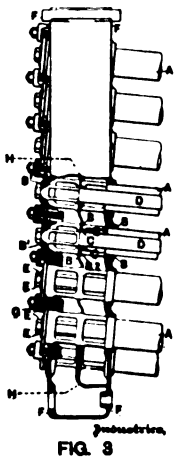

FIG. 3

side sectional elevation of such a boiler, Figs. 2 and 3 being enlarged details showing the connections of the tubes. This boiler is composed of one or more boiler tubes and circulating tubes substantially as shown, the connections of said tubes being as follows:—The boiler tube A is fixed upon a piece B of malleable iron of lantern-like form slightly conical on the outside and closed at B^1 and having a partition at B^2. Upon the part B^1 is fixed a piece C, which carries the circulating tube D. A plug E is screwed into the end of A, and, extending as far as the partition B^2, is connected to the end of D, the said extension having openings formed in it. These tubes are fixed in a collector F, in the opposite sides of which are made conical openings, which

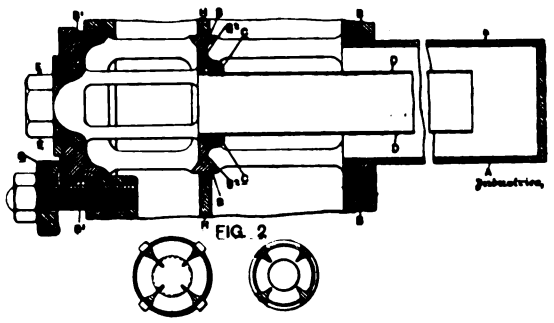

FIG. 2

correspond with the conical faces of the lantern-piece B, said pieces, and so the boiler and circulating tubes, being held in place by means of a safety fixing-bar G. The interior of F is divided longitudinally by partition H, so that the tubes are in equilibrium. Claims: (1) The new arrangement of steam boiler, substantially as described and shown; (2) the combination in a generator of two concentric tubes mounted on one or several collectors; (3) the arrangement, which permits each of these generators placed in a collector to be in perfect equilibrium and to be capable of being dismounted wholly or in part entirely at the front of the generator, all substantially as described and shown.—No. 1052. January 20th, 1891. 8*d.*

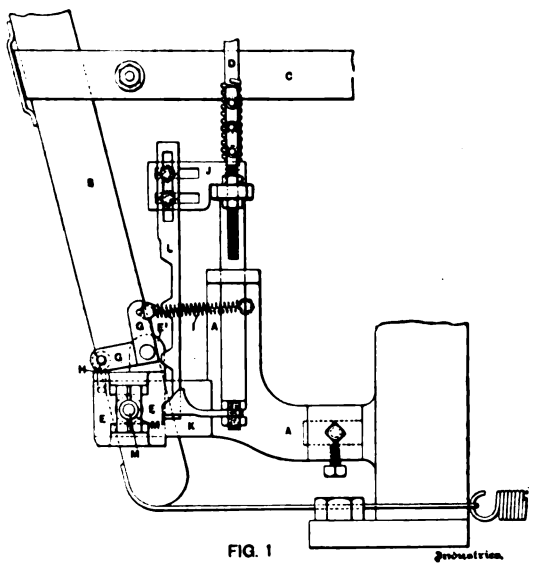
SHAPING MACHINE TABLES.—*J. R. Robinson & E. Rhodes, both of Leeds.*—The invention relates to an apparatus for holding the material to be operated upon. The apparatus is applicable to the jaws of parallel vices used for holding the metal whilst being cut, or it may be independent of the vice and secured to the machine table, and consists in forming on each vice jaw, or on separate blocks, a hinged jaw, centred on a pin acting as a fulcrum, the jaw being provided with a cut facing for holding the material to be operated upon. On nipping the material to some extent between the jaws by the vice screw, or placing it between the separate blocks secured to the table, the material is finally secured by tightening screws passing through some portion of the hinged jaw, by which the face of the screw is caused to grip the material, and at the same time press it downwards on to the table. Claims: A block or other support, to which is hinged on a fulcrum a vice jaw in such a manner that the material is secured between the jaws by a screw passing through a lug, all substantially as described.—No. 17588. November 1st, 1890. 6*d.*

PILE DRIVING MACHINES.—*W. Hood, Pernambuco, Brazil.*—To the chain is attached a frame carrying two or preferably three pawl levers with their lower ends latch-shaped, these levers being arranged radially round the centre of the frame and loaded so that their latch ends lie inwards towards the centre; the upper ends of the levers are curved a little inwards. To the top of the "monkey" is attached a stem carrying a cone, the base of which forms a shoulder round the stem. At or near the top of the frame of the machine is suspended a bell-shaped casing through which the chain passes, and this bell can be raised or lowered according as a greater or less descent of the "monkey" is desired. The operation is as follows:—On lowering the chain the pawl levers, encountering the cone of the "monkey," latch over it and catch under the shoulder at its base. On now raising the chain, the "monkey" is raised until the ends of the pawl levers enter the bell and are pressed inwards, thus withdrawing the lower ends from under the shoulder of the "monkey" cone, so allowing the latter to fall. Claims: In a pile driving machine the combination of the stem shoulder and conoidal head of the "monkey," the frame suspended from the chain with latch levers pivoted thereon, and the hollow cone to receive the upper ends of the latch lever substantially as described.—No. 7797. May 19th, 1890. 6*d.*

RAILS, FISH-PLATES, AND CHAIRS.—*J. Edwards, Folkestone, Kent.*—According to this invention the rail is made reversible, the groove between the two flanges on each side of the rail being rectangular. A projection on the upper end of the inside fixed jaw enters the rectangular slot on one side of the rail, whilst a similar projection in the form of a rabbit on a second and loose jaw partly enters the groove on the other side of the rail. This jaw, as well as the outside fixed jaw, is so formed that it can be held between the latter and the rail. One half of the fish-plate is made to fit the section of rails in use at present, the other half being made to fit the improved section of rail. Claims: (1) The use of a reversible rail; (2) a loose jaw shaped substantially as described.—No. 4722. March 26th, 1890. 6*d.*

DOUBLE-HEADED SPLIT BOLT.—*W. Marsh, London.*—The invention relates to bolts or pins for connecting together shackles of chains, &c., and is constructed as follows:—A bolt having a head at either end, one end of which is split in such a manner as to allow it to close while passing through the hole, the two parts of the split end of the bolt being pressed through the hole, but springing back to their normal position immediately after passing through, and the bolt being prevented passing back again. In modifications, the pin is tapered at the split end so that the head on that end is about the same diameter as the solid part of the pin, the two parts of the split being forced apart after it has been inserted by screwing a tapered pin into the slot. Four claims are made, embracing the double-headed split pin constructed substantially as described, with several modifications.—No. 7133. May 7th, 1890. 8*d.*

LOOMS.—*I. S. Lodge & G. Littlewood, both of Huddersfield.*—The invention embraces a method of preventing the breakage of picking sticks of looms when the shuttle box either becomes wedged while changing or does not complete a change. Fig. 1 of the accompanying illustrations is a front elevation, and Fig. 2 a side elevation partly in section of a picking stick bracket, a portion of the box-lifter rod and picking stick, to which the present improvements are applied. The picking stick bracket A, picking stick B, picking strap C, and box-lifter rod D are of the usual construction. Fixed to A is a box-shaped bracket E,



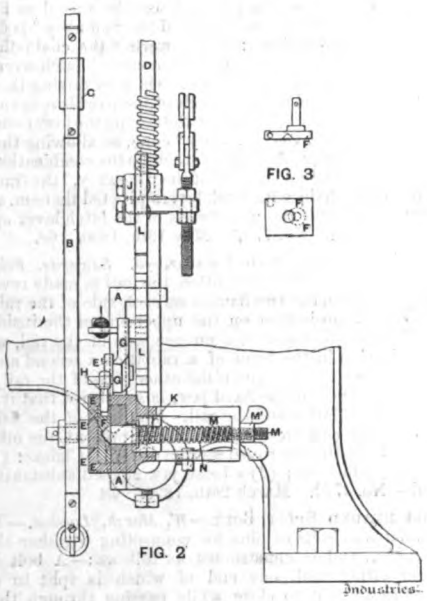


FIG. 1

within which slides a plate F (Fig. 3) carrying the picking stick stud projecting through a horizontal slot in E. Pivoted on a projection E^1 on E is a bell-crank lever G, on one end of which is suspended a pin H, whilst the other end is connected by a helical spring I to A. This pin, when the parts are in their normal positions, projects through a hole in E into a recess in the edge of F. Mounted on the box-lifter rod D, above the ordinary heavy sleeve, is a bracket J, and between the lock nuts is a forked bracket K, between which is mounted a bar L capable of horizontal and vertical adjustment, as shown. This bar is provided with V-shaped projections corresponding in number and distance apart from centre to centre to the number and distance apart of the shuttle boxes. Against the bar is pressed a V-shaped projection on the lever G by spring I. To prevent the accidental displacement of F a bolt M, supported by a bracket on E pressed forward by spring N, passes through E, and the point thereof enters a shallow counter-sink in F; said bolt is made adjustable by means of wing nut M^1. From the above, it will be seen that the plate F will be locked in position by pin H when each change of the shuttle box is complete, but will be free when the changes take place. Should the shuttle boxes be arrested therefore, in any intermediate position so that the pick cannot take place, the plate F, being unlocked, will be free to be thrown out by the pull

Digitized by Google

of the picking strap and breakage of the picking stick will be thus prevented. Claims: (1) In a loom, the employment of a dislodgeable slide carrying the picking stick stud, which slide is locked when the shuttle boxes have completed a change but is unlocked when the shuttle boxes occupy an intermediate position, and is then free to be thrown out by the pull of the picking strap, as specified; (2) the means for locking and unlocking the said dislodgable slide by the up and down movement of the box-lifter rod,

applicable to looms with any number of shuttle boxes, as described; (3) the device for retaining the dislodgable slide in position when unlocked to prevent accidental displacement thereof,; (4) a modification of the locking device applicable for two-box looms; (5) the apparatus constructed and operated substantially as and for the purpose specified.—No. 7100. May 7th, 1890. 11*d*.

Apparatus for the Manufacture of Illuminating Gas.—*R. Mannesman, Landore, R. S. O., South Wales.*—The object of the invention is to effect the heating from within the retorts by burning a portion thereof, and storing up the heat generated in incandescent coke, the heat of which is transmitted by means of the produced gas itself to the fresh gaseous coal. Referring to the annexed illustrations, Fig. 1 is a vertical section and Fig. 2 a sectional plan of an apparatus for this purpose, in which two retorts A A¹ are employed in combination with one gas main B and one chimney flue C. The charging hopper D, for feeding fuel periodically into the producer, is closed by a valve E, and the upper end of the producer communicates by a branch tube F, with a tube G common to both producers, communicating at its lower end by two branches H with the ashpit of the producer. At I the producer has an annular cavity, which communicates by a tube J with a valve chamber K, communicating by a pipe C with a chimney flue, the openings of the tubes J in the valve chamber K being controlled by one and the same valve M, carried by an arm M¹, which in one position closes the communication between the producer A¹ and the chimney flue C, leaving the communication between A and the chimney open, while when in the opposite position said communications are reversed.

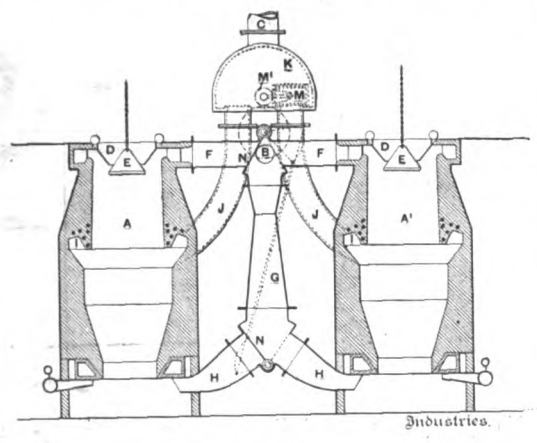

FIG. 1.

In the tube G are arranged two flap valves N, mounted on spindles, by turning which they are made alternately to open the communication between A¹ and the tube G, as also with the gas main B, and to close the communications with A, as shown in the illustration, while in the opposite position of the valves the said communications will be reversed. O are pipes for leading air under pressure to the lower ends of the producers. The action is as follows, reference being made, however, to only one of the retorts, the action of the second retort being similar, only in reverse order. After the retort is charged with coal and is ignited at the lower end, air is periodically admitted to the ashpit, and at the same time the flue leading to the chimney is opened. The fire so extends upwards, at the same time converting the lowest part of the charge into incandescent coke. The air supply to the ashpit is then closed, as is also the chimney flue, and the gas outlet and the communicating channel between the upper and lower ends of the producer are opened, whereupon a portion of the gas produced is caused to pass, by suitable means, from the top to the ashpit. A portion of the illuminating gas is thus forced to pass through the incandescent coke, so taking up heat therefrom, and in ascending it gives off such heat again to the upper cold part of the charge, thus heating the same, and eventually distilling off the volatile constituents. A portion of the gas thus produced is again drawn off, as before, for effecting a second circulation for the transmission of heat from the coke into the upper part of the charge, while the remaining

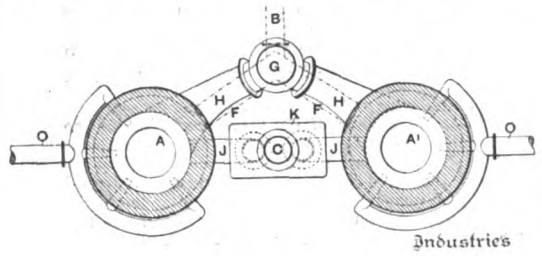

FIG. 2.

portion is led off into the gas main, and is there cooled, purified, or otherwise treated, in the usual manner. Three claims are made, embracing the method and apparatus for the production of illuminating gas substantially as described.—No. 1237. January 23rd, 1890. 8*d*.

ELECTRICITY.

Transformers.—*L. Pyke & H. T. Barnett, both of London.*—The different layers of the primary and secondary coils are separated by means of porous paper, and the whole is suspended in a glass vessel, in which circulates a liquid insulator, such as paraffin, which has been previously dried by passing through a filter of powdered potassium. The transformer is so arranged that the liquid insulator may have as much facility for circulating round and through same as possible, and to this end the surface of the container is corrugated, or a cooling vessel, connected to the container by suitable pipes and placed at a higher level, may be used. Five claims are made, embracing the method of insulating and cooling transformer coils as described.—No. 3900. March 12th, 1890. 6*d*.

Transformers.—*J. A. Kingdon, London.*—The cores of the transformers embraced by this invention are made of a number of thin plates of soft iron piled one above the other. These plates are of the same width, but at intervals one or two are longer than the rest. Insulating material is wrapt round the pile of plates, and primary and secondary coils of insulated wire wound outside said insulating material. The primary and secondary coils are preferably split up into a number of sections placed alternately and separated by insulating material. Outside the coils and separated from them by insulating material or an air space are wound a number of coils of thin iron strip. These coils are in contact with and wound round the projecting ends of the iron cores and are at right angles to the wire coil. Bolts pass through the ends of the longer plates and hold the whole together, which is then cemented in a metal box. Claims: (1) An electrical transformer having its core constructed of iron plates, some of which are longer than and project beyond the rest, and having its magnetic circuit completed by winding iron tape or wire outside the primary and secondary coils between the projecting iron plates as described; (2) the combination in a transformer of short iron plates with primary and secondary coils, long iron plates, and coils of iron tape; (3) the combination of short iron plates separated at intervals by long iron plates with coils of iron tape and coils of copper wire; (4) the core of a transformer as described; (5) cementing a transformer into a metal box; (6) the combination of a transformer and metal box as described.—No. 7624. May 16th, 1890. 8*d*.

Electric Meters.—*S. Z. de Ferranti, London.*—The invention relates to meters in which a bath of mercury is caused to rotate by a passing current, which rotation operates recording mechanism, as described in prior patents, No. 5926 of 1883 and No. 701 of 1887. A meter of this description is shown in the annexed illustrations, of which Fig. 1 is a vertical section, Fig. 2 a side

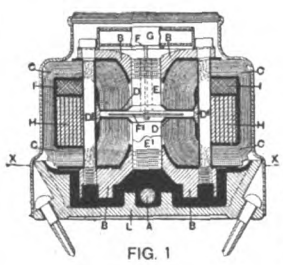

FIG. 1

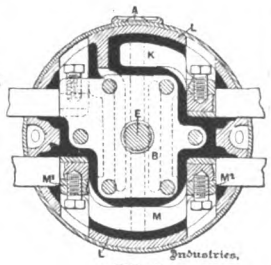

FIG. 3

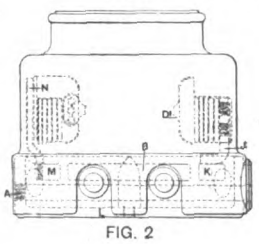

FIG. 2

elevation, and Fig. 3 a horizontal section on line X X, Fig. 1. Held together by means of bolts A and clamping plate B are two annular troughs C formed of a number of stamped sheets of tin plate, which when placed together are heated sufficiently to cause the tin coverings to unite. These troughs hold between them the mercury bath formed of two discs D connected together at their peripheries by clamping ring D¹. Screwed into the centre of the discs D are the ends of screws E E¹, the other ends of which are screwed into the centres of the plates B. The screw E is hollow, and the spindle F of the disc F¹ which is immersed in the mercury rises up through the hollow to the recording mechanism contained in a casing G. Between the troughs C are also held the main coil H, formed of strips of metal, and an additional coil I, through which a branch circuit from the mains is allowed to pass as described in patent No. 701 of 1887. A vertical division for preventing circular currents is formed across one side of the annular casing formed by the thin iron troughs. A vertical division is also formed partially through the opposite side of the trough. At one side the vertical division is utilised by placing in it the conductor J leading to the outer end of H. The conductor is led downwards and connected to a bar K, embedded in sulphur in the iron casing L of the meter, in which is formed a socket to receive one of the conducting wires leading to or from the meter. On the opposite side of the casing the conductor to the outer end of the shunt coil I is made to lie in the division. The bottom clip plate B is also embedded in sulphur in the centre of the cast-iron base L. It is formed with a socket in which the end of one of the pair of conductors of the supply main may be attached. The end of the other conductor of the supply main is similarly clamped in a socket M¹ formed in a conducting bar M which is also embedded in the sulphur. At the opposite end of the bar is another socket M² in which the end of one of the conductors of the main to be supplied is held. In this way when current passes to the bottom clamp plate B from the supply main it passes by the clamp screws A to the top clamp B, and from both clamp plates through the screws E, which pass to the centre of the mercury bath and through the mercury to the outer ring D¹ of the mercury bath and from there to the inner end of the main coil H and through the coil to the conductor bar J which is attached to it, and so to the bar K and the main to be supplied. The outer end of the additional or shunt coil I is connected by the conductor N to the conductor M, which has one end of the supply main and of the main to be supplied attached to it. The inner end of the shunt coil I is connected to the outer ring D¹ of the mercury bath. Twelve claims are made.—No. 3096. February 26th, 1890. 11*d*.

Dynamos.—*W. Emmott & J. H. Rider, both of Halifax.*—The improvements relate to the winding of armatures of alternate current dynamos, the core of the armature being of the drum or ring type. A number of conductors are laid side by side upon the outside of the armature in a direction parallel to the spindle. They are then bent under an insulating piece on the end plate of the armature and returned on the outside of the armature, and near to the first set. This process is continued until the winding is completed, the bands of conductors forming in plan a sinuous curve. The ends of the conductors are brought out near each other on one side of the armature, and are then connected, the final ends being carried to the collecting rings. The spaces between the windings on their periphery may be filled with non-conducting material and the whole secured by wire binding. Five claims are made.—No. 5562. April 12th, 1890. 8*d*.

CHEMISTRY.

Treatment of Metal Bearing Bodies.—*W. C. Loe, London*—This invention embraces a method of recovering metals from their matrices, especially of precious metals. In dealing with free milling matrices, or only gold-bearing materials pulverised, the bulk is calcined with about 1-40th part of potassium or any other suitable alkaline agent and 1-80th part of sulphur to a dull red even heat, and so maintained for two to four hours. By using sulphur and potassium, persulphide of potassium is formed, which takes up the metals. After the material has been washed in a slight solution of persulphide of potassium at about 200°, the solution is drawn off and the persulphide of gold precipitated and refined in the usual manner. In dealing with refractory or complex ores, the materials, pulverised, are mixed to pug consistency with a saturated solution of proto-sulphate of iron, dumped, calcined, and again saturated with a solution of sulphide of potassium, and allowed to remain about forty-eight or sixty hours. The metal-bearing materials now part with the iron and gold, which are taken up with the sulphur, and form sulphides of metals. The treated material is then washed in water at 200°, and, when settled, the solution is drawn off. The potassium acting on the silicious matter releases the metals, and they are then precipitated with a saturated solution of sulphide of lime, which takes up the metals and forms an intense black slime. This, on being washed, disengages all sulphurous gases, when the said slime may be fluxed and refined in the ordinary way. Claims: The described means and process for the extraction and recovery of metals from metal-bearing bodies (without the use of agents such as mercury, chlorine, or electricity) by regulating the necessary agents to set up chemical conception whereby the metals are released from their bodies and form sulphides.—No. 5937. April 18th, 1890. 6*d*.

MISCELLANEOUS.

Manufacture of Iron and Steel.—*A. Turner, Greenock, & A. & M. B. Baird, both of Glasgow.*—The process embraced by this invention is as follows:—A quantity of the crude metal is reduced to a molten state in a furnace and a quantity of pure metal reduced by electricity then added. The reduction of the pure metal is effected by placing it in proximity to the furnace containing the crude molten metal and the passing through it a current of electricity. Claims: The improved process of manufacturing iron and steel, substantially as described.—No. 5545. April 12th, 1890. 4*d*.

Copies of the British specifications may be obtained on application to H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.*

SIMPSON'S TRAIN INDICATOR.

We give illustrations herewith of a train indicator which has been very largely adopted by the Lancashire and Yorkshire and several other railway companies. As will be seen, it consists of a wooden frame, which is fitted with drums and oscillating shutters, to enable the names of the stations at which a train will stop and the time of its departure to be displayed. The aim of the invention is to provide a ready means by which a number of combinations of names can be easily shown, and there is hardly a limit to the number obtainable from a small-sized machine. At the upper portion of the frame a special compartment is formed, in which three drums are placed. One of these is numbered on its periphery with figures from 1 to 12, representing the hours; the second one is numbered 1 to 5, and the third from 0 to 9, the two latter representing minutes. By bringing any one of these series of figures behind an aperture cut in the front of the compartment containing the drums it becomes visible to intending travellers. The mode of setting these drums is as follows:—On the axis of each drum is a small pinion A gearing with a toothed rack B fastened at the upper end of a rod of timber C, which at its lower end has a ratchet D fixed. The teeth of the ratchet are so pitched that by moving the rod one tooth the drum is rotated a distance equal to the distance apart of the figures. When the rod is lifted, as it can be by hand, it is retained in position by the spring pawl E, shown. This arrangement of drums is shown in Fig. 1 in front elevation, in Fig. 2 in side elevation with the cover removed, in Fig. 3 in sectional plan through the line X X, and in Fig. 4 in sectional plan through Z Z.

Referring now to Fig. 2, each name board F is hinged on a centre, and is triangular in section, as shown. On one flat only of the board the name of a station is painted, and a pin or tail G projects backwards from the board. With this tail a pin H, which is fixed to one of the vertical rods J, engages, when thrust through the rod sufficiently far, and it is obvious that the number of boards which will be affected by any of the rods depends upon the number of pins in it which engage with the tails at the back of the boards. Thus it is possible to fix the pins in any of the bars or rods so that all the name boards will be affected, or only one may be engaged. To meet the need for several combinations a number of vertical rods, as shown in Fig. 4, are used, these corresponding in number to the combinations required. The pins are fixed as desired, access being obtained from the back of the case for this purpose. A rocking shaft M, in which a long key is fastened, is connected with the door L of the frame, shown open in Fig. 2, by the levers indicated, and sliding on the key is an adjustable arm or lever, which can be moved along under any of the rods according to the combination required. After this is done the mere closing of the door raises the rod and oscillates the name boards, making the names of the stations it is desired to show visible from the outside.

There are many methods of arranging this indicator. It can be made single or double faced, and two can be placed side by side so as to indicate the trains leaving adjacent platforms. We can testify to the convenience which the indicator affords to the travelling public, and to further this a full list of the trains departing from the platform can be placed in a glass-fronted case below the name boards, and a hand arranged to point to the departure platform. The inventor is Mr. D. K. Simpson, St. George's Crescent, Liverpool.

ARTS AND CRAFTS AT THE GLASGOW EAST END EXHIBITION.

The East End Exhibition at Glasgow has, throughout its course, been extremely successful in point of attendance. There are few exhibits of special novelty so far as mechanical interests are concerned, but there is one department upon which much care and thought have been expended, and which is exceptionally instructive and interesting. This is an Arts and Crafts Exhibition, somewhat on the model of the now well-known annual exhibitions held under that title in London. Although Glasgow is associated in the minds of most people with the heavier processes of manufacture—with iron smelting, steel making, shipbuilding, and the like—there is, nevertheless, great variety of the finer industries involving the exercise of artistic skill both in design and in craftsmanship. Thus, Glasgow divides with Manchester the trade of cotton printing, and with Kidderminster the trade of carpet weaving, and with London and Lancashire the trade of wall paper printing. All these industries involve the application of art to designs as well as of highly developed technical skill in the choice of materials. In all of these branches the products of the Glasgow factories bear a high reputation. In addition to these large industries are the relatively smaller, but still important, crafts of wrought iron and hammered metal work, artistic glass making, glass painting and staining. The remarkable and satisfactory feature about the development of these industries in Glasgow is that the lines upon which they have grown are not merely imitative. The artists and craftsmen who have been engaged in this development are really by degrees effecting an indigenous artistic growth. The Scottish artists and handicraftsmen are able to supply from their studios and workshops in Glasgow and Edinburgh native works of art which will bear comparison with the products of other cities whose artistic wares have a reputation of longer standing. Hitherto, examples of artistic work have for the most part been sent for exhibition to London. About two years ago a small exhibition of work was held at Edinburgh, and some objects appeared at all the recent international exhibitions; but the whole matter has been much more thoroughly developed at the East End Exhibition. Among Glasgow exhibits which have appeared in London may be mentioned the large designs in cast metal by Mr. Kellock Brown, a Glasgow sculptor, executed by him for the Savoy Hotel. Though the designs were made in Glasgow, the work was cast in London. As an example of an opposite course, the greater part of the metal work for the Church of the Holy Trinity at Chelsea, though designed in London, was cast by the Glasgow firm of Messrs. Wm. Sherriffs & Co.

A steady and increasing demand has been noticeable for some time for wrought iron, chiefly in the form of objects for domestic use and ornament. This industry has grown up in Glasgow during the last few years, and has effected somewhat of an attack upon the place previously occupied by cast iron. There is thus a chance of wrought iron resuming the position it held as a material in frequent use under the hands of the artist workmen in the Georgian period. Railings and gates are now being made in Glasgow quite as fine as one may find in cities like Bath, which have survived the change of fashion.

Digitized by Google

The attempt made in the East End Exhibition to bring together a representative collection of work designed by Glasgow artists and executed by Glasgow workmen has been a conspicuous success. The success has, indeed, been so encouraging, that those who originated and carried out the idea hope soon to be able to promote a special Exhibition on a more extended scale. A suggestion has been made that the Corporation of Glasgow should promote an exhibition of the artistic handicrafts of Scotland, and there seems some probability of such a design being carried out. Among the present exhibits perhaps the most interesting are the works in wrought iron. The examples shown by Mr. James Adam possess qualities of design and workmanship of a very high order. A panel designed for the new offices of the Fairfield Shipbuilding Company by their architect, Mr. John Keppie (of Messrs. Honeyman & Keppie), and a flower stand, with delicate and intricate foliage, are among the best examples of this class. Mr. Kellock Brown exhibits a great variety of hammered metal work, consisting of sconces, friezes, plaques, and salvers. Several examples of metal casting by "cire perdu," or the lost wax, process are shown by Messrs. Wm. Sheriffs & Co. This method of bronze casting was formerly confined to Belgium, and is one of the most recent additions to the artistic industries of Glasgow. The tradition followed has been that of Scotch sixteenth century work, though a free treatment of the styles is not absent. The art of glass staining is represented by the work of Messrs. J. & W. Guthrie and Stephen Adam & Co. The work of the first is specially noticeable for its specialised colour treatment, and for the absence of that German Gothic feeling which animates so much of our ecclesiastical glass. Mr. Stephen Adam confines himself more closely to the following of traditional treatments, save in some of his smaller products, where there is evidence of a more definitely artistic feeling. Decorators have submitted schemes for internal decoration by paint and paper. The more noticeable of these exhibits are those of Messrs. George Walton & Co., and the examples of stamped leather designed by well-known men, and manufactured by the Lionsdale Patent Leather Company. The Messrs. Templeton send two rugs and one large carpet, all animated by the spirit of the old work of India and Persia in point of design, but restrained by the somewhat dull and depressed schemes of colour which this firm affects. Messrs. T. & D. Wilson & Co. and Inglis & Wakefield are represented by chenille and harness muslin curtains. A very complex piece of wood carving, by Mr. James Crawford, represents this class of work. Special mention should be made of the very remarkable plaster work sent by Messrs. MacGillvray & Ferris. This firm has really effected a revolution in the trade, their highly artistic work having demanded and secured general recognition.

Supplementing all these practical exhibits, and showing how a real link can be made between the work of design students in a school and their future work when acting in a commercial capacity, come the examples of students' works sent in by the Glasgow School of Art and Haldane Academy. The tendency shown in these studies seems to be the right one—namely, that of educating a designer for future rather than for present use. Acting upon the basis that no school should produce designs, but rather designers, a maximum amount of knowledge is imparted to the student, and thus, the largest future demand being met, all other demands naturally fall within the student's powers. The examples are designs for carpets and other textile fabrics, wall papers, metal work, stained glass, and pottery, together with the preparatory and coincident studies in painting work from the antique and life and modelling necessary for the purpose. Three gold medal studies—two for carpets and one for a printed hanging—are noticeable, together with other premiated works in modelling, textile fabrics, and stained glass, which, from the awards made them, seem to have taken a good place in the national competition. Just now, when the cry is all for technical education and practical utility in school work, these studies from the School of Art should prove that Glasgow at least is becoming alive to the real meaning of these terms.

THE PALERMO EXHIBITION.

In our issue of the 20th February last, we referred to the Exhibition which is to be held at Palermo from the 1st November next until the 31st May, 1892, and we mentioned the various sections which the Exhibition will comprise. We now give on the opposite page a general view of the buildings which are at present being constructed for this Exhibition, and which have been designed by Professor Ernesto Basile. In the grounds illuminated fountains are to be erected, while the tower shown in the illustration will be used as an astronomical observatory. The Exhibition and grounds will be lighted throughout electrically. No charge for space is being made in this Exhibition, and applications for space by intending English exhibitors should be sent to the Italian Chamber of Commerce in London, 4, St. Mary Axe, E.C., not later than the 30th inst. We are indebted to *Palermo e l'Esposizione Nazionale* for our illustration.

BOILER DEPOSITS.*

(*Concluded from page* 364.)

The next point I attempted to determine was the effect which these oily deposits had in allowing excessive heating of the plates to take place, and retarded the heating of the water. A clean iron vessel was taken, and a known volume of water placed in it, and heated by a carefully regulated Bunsen flame, the water being raised to the boiling point in ten minutes; this experiment was repeated a second time with the same result, and the vessel was then lined with a coating of deposit found in the bottom of the boilers which had collapsed, and rendered binding by admixture with a small trace more valvoline. This coating was laid on $\frac{1}{16}$in. in thickness, and the former experiment repeated, the same flame being used and the same volume of water taken, with the result that it took fifteen minutes before the boiling point was reached, showing that, even if no damage resulted to the plates from overheating, such a deposit would cause a large increase in the fuel used.

In attempting to ascertain to what extent extra heating of the plate took place from this cause, I employed a series of substances of known igniting and melting point, raised the water in the various vessels to the boiling point, and then brought the clean bottom of the vessel in quick contact with the test substance, and took the results as indicating the temperature of the exterior of the plates.

Clean vessel ...	Sulphur did not melt ...	below 115° C.	= 239° F.
Coated vessel...	Sulphur melted but did not inflame	above 115° C.	= 239° F.
		below 250° C.	= 482° F.
	Guncotton ignited	above 200° C.	= 392° F.

So that the $\frac{1}{16}$th of deposit caused with a slow heat a rise in temperature of the plate from under 115° C. or 239° F. to over 200° C. or 392° F. It is manifest, however, that the fiercer the heat the more marked will this overheating become, and in the next series of experiments the Bunsen flame was replaced by an atmospheric blowpipe, and the temperature attained, tested in the same way as before.

Clean vessel ...	Sulphur did not melt...	below 115° C.	= 239° F.
Coated vessel...	Guncotton ignites.....	above 200° C.	= 392° F.
	Tin melts	,, 228° C.	= 444·4° F.
	Sulphur ignites.....	,, 250° C.	= 482° F.
	Lead melts.....	,, 334° C.	= 633° F.
	Zinc melts (just)	,, 423° C.	= 793·4° F.

Whilst, on replacing the atmospheric burner by an oxy-coal gas flame, I found no difficulty in fusing a hole in the bottom of the vessel, which was made of thin wrought-iron plate, showing that a temperature of 1,500° C. = 2,732° F. had been attained, and it is therefore manifest that, with the fierce heat existing in the boiler furnaces, given an oily deposit only $\frac{1}{16}$in. in thickness, the plates will readily be heated to a temperature at which they are totally unable to withstand a pressure of 80lb. of steam, and collapse of the furnace crowns must follow.

The great points to be sought in a good lubricating oil are that it shall be a pure mineral oil, and that its boiling point shall be well above any temperature likely to be attained in the cylinder. Oils satisfying these requirements can readily be obtained, but users of lubricants must remember that, in order to obtain them free from any constituents of dangerously low boiling point, expensive processes have to be resorted to, which must of necessity increase the price of the oil, and that it is useless to expect to obtain a really good lubricant at a low figure. The great advantages of a good mineral oil cannot be too strongly insisted on, and any lubricant containing animal or vegetable oils to give it body should be unhesitatingly discarded. The mineral oils are not fats, but hydrocarbons—compounds of carbon and hydrogen—and the portions used for lubricants are those left after the more volatile constituents have been distilled off, and they differ widely from animal and vegetable oils, which contain so-called fatty acids, which are liberated from them by the action of superheated steam, and these acids attack iron, copper, and copper alloys with the greatest readiness, forming metallic soaps, which are compounds of the fatty acids with the oxides of the metals, and so cause serious damage to both boilers and fittings. The animal and vegetable oils, in contact with air, especially when heated, take up oxygen, and become gummy and resinous, and gradually so stiff that frequent cleaning becomes necessary, a trouble entirely avoided with mineral oils.

In dealing with the prevention of such deposits, it seems to me that the most feasible plan is to pass the feed water through a long tube filled with clean coke in pieces the size of walnuts, which would act as a scrubber, and would free the greasy water from the traces of oil, and prevent their going forward to the boiler. I have already pointed out that the collapse of furnaces from the presence of oily deposits almost invariably takes place in boilers fed with fresh water, and that oil, when it goes into the boiler, floats, because it is specifically lighter than water, until solid particles of calcium compounds coming in contact with it and imbedding themselves in it so increase its weight, that, reaching the same density as the water, it commences to circulate with the convection currents in the water, and is so drawn down, and attaches itself to tubes and furnace crowns, causing, eventually, damage. In the case of a transatlantic liner using fresh water only it takes at least four days' hard steaming to bring the density up to $\frac{1}{32}$nd, whilst if sea water had been used the density would have started at this and would never, after the first few days, have been much below $\frac{3}{32}$nds, and the oil would have remained as a scum, and have reached the furnace crowns.

In my last paper on boiler incrustations I pointed out that it was quite possible to prepare sea water in such a way as to practically prevent any serious deposit forming from it, and the same process would prevent the trouble I have now been describing to you. In the summer of last year Mr. Biles, who is always to the front when he thinks there is a chance of improving marine engineering, kindly gave me the opportunity of trying the effect of prepared sea water upon a crane boiler at the Naval Construction Works, at Southampton, and, after a few preliminary experiments to determine the best form in which to work the "precipitator," the boiler was worked continuously for a month with water drawn from the Itchen half an hour before high tide, at which period analysis showed that the water was to all intents and purposes sea water, plus a fair amount of suspended mud; this, after preparation in the "precipitator," was fed into the boiler, and on opening it in the presence of Mr. Milton, Mr. W. H. Riley, R.N., Mr. Biles, Mr. Gearing, and Mr. Dusantoy, it was found perfectly clean, the surfaces looking as if they had been given the thinnest possible coat of whitewash.

The process employed was to add to the sea water a known quantity of precipitator powder, consisting chiefly of soda ash, and, having done this in a closed vessel, to heat the mixture by blowing into it waste steam, until a pressure of from 5lb. to 10lb. was created, and under these circumstances practically all the magnesium and calcium salts separate from the water and are easily got rid of by filtering it under pressure into the hot well. I had proposed in the first case to heat the liquid by blowing the steam through a coil in the precipitator, but practical experiments soon showed that the heating surface was not nearly enough, and so the waste steam was simply blown in, allowance being made in the precipitator for the water due to the condensation. I also found it aided the reaction to heat the water first just to boiling point before adding the precipitator powder, as under these circumstances the deposit settled more quickly and threw less strain upon the filters. The precipitator was 6ft. 4in. high and 3ft. in diameter, and held a ton of water, and the time taken, from the first running the sea water in to its delivery into the hot well, was 1 hour 15 minutes, so that in practice, giving plenty of time between the makes, it would be perfectly easy to prepare 8 to 12 tons in the 24 hours with a small precipitator of the size used. The prepared water has a density of $\frac{1}{32}$nd, and may with safety be evaporated until its density is $\frac{5}{32}$nds, the salts present not crystallising out until a density of from $\frac{6}{32}$nds to $\frac{7}{32}$nds is reached.

Professor Doremus, of the College of the City of New York, proposes to use sodic fluoride as a precipitant for the scale-forming constituents of sea water, as a smaller weight is required, and the action is more rapid and more perfect. The great objection has, up to the present time, been its cost, but I am informed that this has now been so far reduced as to bring it within the scope of extended commercial use; and, should it be used on a larger scale, the price could be readily brought much lower. Professor Doremus claims that the precipitation of the calcium and magnesium salts takes place with very great rapidity, that the sediment shows no tendency to cake or adhere to the sides of a hot vessel, and that it is less bulky than the precipitate formed by soda ash. In preparing sea water in the way I have proposed, every precaution must be taken to add slightly less of the precipitant than is necessary to entirely throw down the calcium and magnesium salts, as it is manifestly impossible in practice to guard against small quantities of sea water finding their way into the boiler either from leaky condensers or else being fed in by the engineer during some emergency, and, if under these conditions any excess of the precipitant were present in the boiler, a bulky precipitate would be thrown down and cause trouble, although it would not bind into a solid scale. There is no doubt that, if Professor Doremus can so reduce the price of sodic fluoride as to enable it to be used for this purpose, it would be of great use, as the fluoride undoubtedly completes its action on the salts of magnesium and calcium more rapidly and thoroughly than the soda ash, and it would be easier therefore to so regulate the quantity added as to remove, say, five-sixths of the injurious constituents from the sea water without allowing any precipitant to enter the boiler.

In conclusion, I will briefly recapitulate the means which seem to me best adapted for preventing the formation of the dangerous organic and oily deposits I have considered in this paper, and these are:—

I.—Filtration of condenser water through a coke column.
II.—Free use of the scum cocks.
III.—The use of water of considerable density rather than of fresh water.
IV.—The use of pure mineral oil lubricants in the smallest possible quantity.

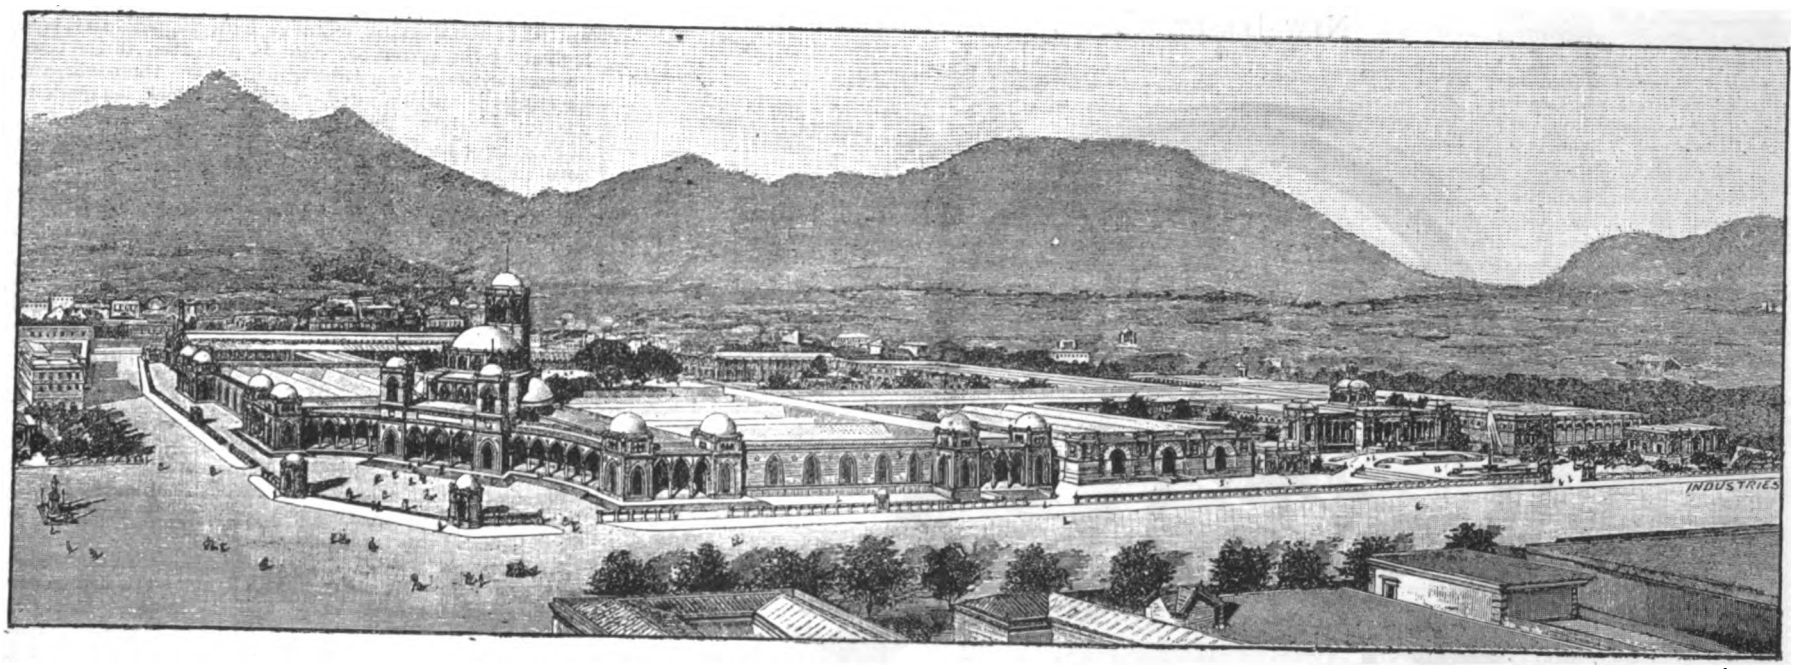
EXPERIMENTS ON THE FRICTION OF A PIVOT BEARING.*

The experiments on the friction of a footstep bearing, which form the subject of the present report, were tried in July, 1890, at Messrs. Simpson and Co.'s works, Pimlico.



Description of the Apparatus.—The apparatus employed in these experiments is shown complete in the accompanying illustration, Fig. 1; and in enlarged detail in Figs. 2 to 4. The bearing experimented on was flat ended and 3in. diameter (Fig. 3). The vertical shaft carrying the footstep F was geared to a horizontal shaft (Fig. 1), which was driven by a belt from the shafting of the works. Variations of speed were obtained by keying pulleys of various diameters on the horizontal shaft. The bearing B was pressed upwards against the footstep by an oil press P with a plunger 6in. diameter. This plunger was made a good but perfectly free fit in its cylinder for a length of 9in., a number of grooves being turned in the cylinder throughout its whole length at close intervals. The pressure was applied by means of a small hand pump, provided with an air-vessel, pumping oil out of a tank into the press. It was found that the

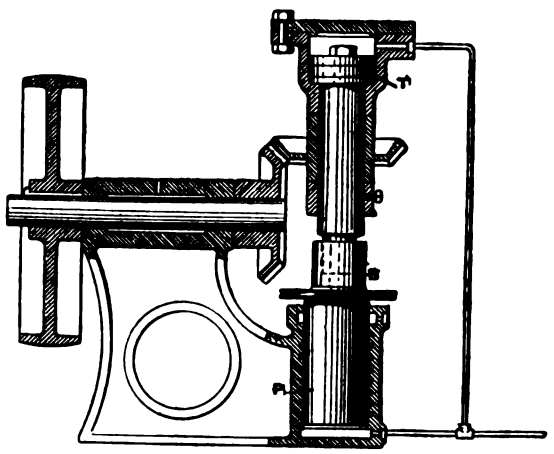
General View of Exhibition Buildings.

leakage of the oil past the plunger, even with the highest pressures, was exceedingly slow, requiring only an occasional stroke of the pump to keep the pressure constant; and at the same time the friction was practically nil. Into the top of the plunger was let a piece of hard steel (Fig. 3) having a conical depression or centre pop, wherein rested a hard steel conical centre, which was formed on the bottom of the plate L that carried the bearing. This plate was circular (Fig. 2) and had a groove turned in its



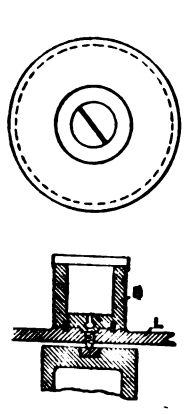


Fig. 1.

Figs. 2 and 3.

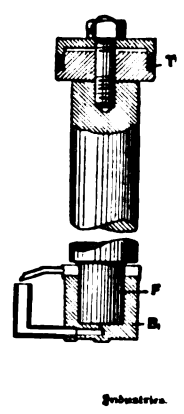

Fig. 4.

periphery; a small chain was fastened to the plate and lay in the groove round a portion of the circumference, from whence it led off to a spring balance attached to the fixed frame of the apparatus; so that the rotation of the plate stretched the spring balance, and the force tending to turn the plate was thereby indicated. The upper end of the vertical shaft that carried the footstep F had a piston T fixed on it (Fig. 4), which revolved in a cylinder 6in. diameter. This upper cylinder was connected by a pipe with the cylinder of the lower press P (Fig. 1), so that, whatever oil pressure there was in the lower cylinder pressing the bearing upwards, there was the same in the upper cylinder pressing the footstep downwards. This was a convenient way of providing for taking the upward thrust upon the experimental bearing. The footstep having been set running at the desired speed, the hand pump was worked until the pressure gauge on the oil press P indicated the desired pressure; and the friction was then read off the spring balance connected with the bearing plate L. The load could be quickly removed from the bearing by opening a cock for discharging the oil from the air vessel of the pump. This method of applying the load was found to be exceedingly convenient, and to be much superior in that respect to any of the methods used for this purpose in the former experiments made by the committee.

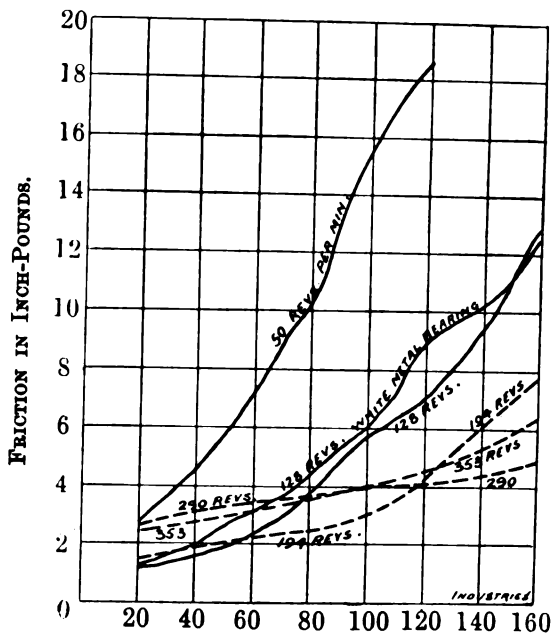

Fig. 5.—Load in Lbs. per Square Inch.

Lubrication.—The first method of lubrication tried was by introducing the oil through a hole in the centre of the bearing (Figs. 2 and 4), and distributing it through two radial grooves extending from the central hole to within $\frac{1}{8}$in. of the periphery of the bearing surface; these two radial grooves were opposite each other, so that they lay on the same diameter. A pipe and a passage drilled in the brass connected an ordinary lubricator with the central hole. When the experiments were started, it was found that the bearing took oil out of the lubricator pipe very fast, and delivered it out at the top of the bearing. This suggested the removal of the lubricator, and the soldering of a piece of sheet brass round the top of the bearing (Fig. 4) so as to collect the oil and return it by means of a small overflow pipe into the lubricating pipe. There was a sufficient space between these pipes to allow the dripping of the oil to be seen, so that the quantity passing could thereby be estimated. Thus the bearing proved to be a most efficient pump, causing a rapid circulation of oil through itself. At first, before the surfaces were worn down to a proper bearing, the oil was observed to be dirty, and charged with particles of brass; as long as this continued, the oil was diverted from the overflow pipe, and run to waste, while fresh clean oil was supplied to the lubricating pipe. When after running a few hours the oil from the overflow pipe was observed to be clean, it was turned into the lubricating pipe, and the bearing was then self-lubricating, and continued using the same oil over and over again.

TABLE I.—Experiments on the Friction of a Pivot Bearing. Steel Footstep on Manganese-Bronze Bearing.

The friction given is that of one face of the flat circular bearing surfaces, at the effective radius of the face—namely, 1in.

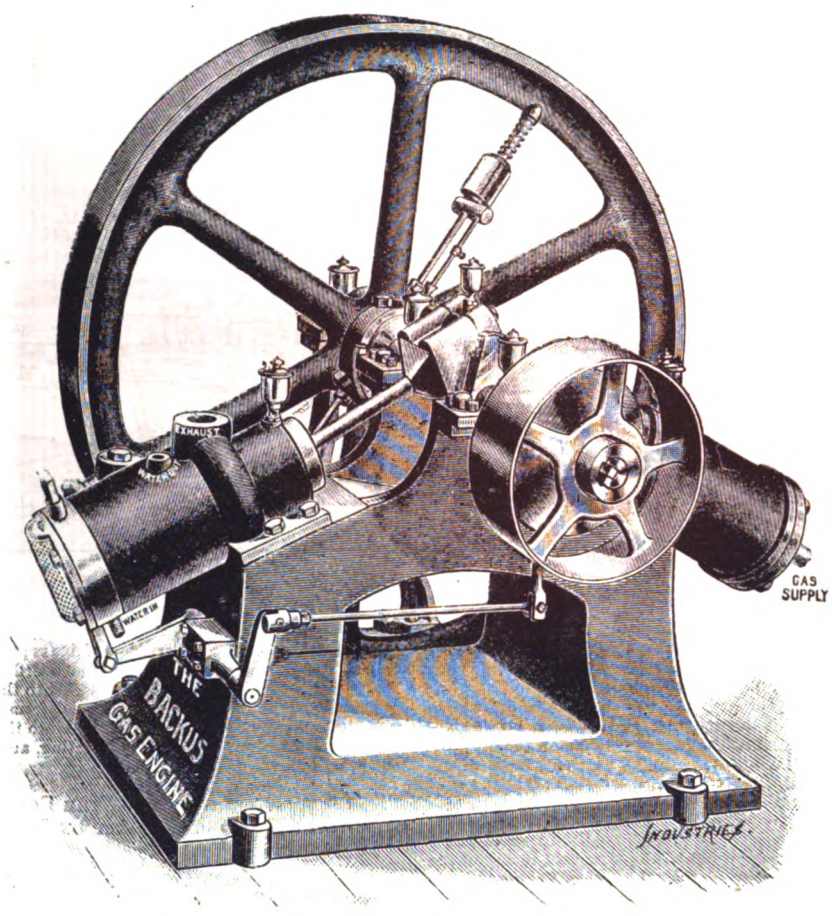

FIG. 1.

50, 128, 194, 290, and 353 revolutions per minute, as shown in Table I. (page 387), and in the diagram (Fig. 5) in which the load is given in lbs. per square inch of bearing surface, and the friction is in inch-lbs. The coefficient of friction is obtained by dividing the friction in inch-lbs. by the product of the load multiplied by the area of the bearing. The radius of 1in. is taken because it is two-thirds of the radius of the bearing. If the flat disc of bearing surface be imagined to be made up of a great number of sectors or triangles radiating from the centre of the circle, the centre of area of any one of these triangles or sectors is at two-thirds of the distance from the apex or centre to the base or circumference. Supposing any one of these triangles to be pulled along in a straight line over a plane surface, the line of force pulling it would pass through its centre of area, because it must be assumed that the friction per unit of surface is the same in all parts of the area of the triangle. It therefore seems reasonable to take two-thirds of the radius of the bearing as the radius at which the force of friction acts, for the purpose of calculating a coefficient of friction which will serve as a comparison between this and the other forms of bearings tried in previous experiments. Of course this view implies the assumption that the pressure is uniform over the entire surface, and that the friction is independent of the velocity. After these experiments with the steel footstep on manganese-bronze, a white-metal bearing surface was substituted for the manganese-bronze, the methods of grooving and lubrication being kept the same. A set of experiments were taken at 128 revolutions per minute, the results of which are shown in Table II., and in the diagram (Fig. 5). It will be seen that the coefficient of friction is a little larger with the white-metal than with the manganese-bronze, but the difference is so small that the results may be looked upon as practically identical; for when the friction is mainly between oil and metal, it should be independent of the nature of the metal. Probably the white-metal bearing was tried before it was worn down to quite as true a surface as the manganese-bronze.

An examination of the tables and of the diagram (Fig. 5) shows that at the higher speeds the coefficient of friction is less, owing to the more perfect lubrication, as shown by the more rapid circulation of the oil. That the lubrication and condition at the surfaces were fairly perfect is shown by the low coefficient of friction, which at the higher speeds with medium loads was in several cases under 0·0050 or $\frac{1}{200}$th.

After the completion of these experiments, the manganese-bronze and the white-metal bearings were tested for endurance at 128 revolutions per minute. The manganese-bronze bearing heated and seized on one occasion with a load of 260lb., and on another occasion with 300lb. per square inch. The white-metal bearing under similar conditions heated and seized with a load of 240lb. per square inch Besides the experiments of which the results are here given, the steel footstep on manganese-bronze was varied by lubricating with three and with four radial grooves; but the friction was from one and a half times to twice as great as with only the two grooves. This fact was carefully ascertained; and the plan shown in Fig. 2 of two opposite radial grooves—or, as they may be called, a single diametrical groove—was adopted for experiment as being decidedly the best.

GENERAL CONCLUSIONS.—These experiments show conclusively that a bearing of this character is capable of very perfect automatic lubrication, if provision is made for allowing the oil which overflows at the top of the brass to find its way back to the bearing surface at the bottom. Also that a single diametrical groove is better than any other plan. The perfection of the lubrication by this arrangement is proved by the low coefficient, which more nearly approaches the low values obtained in the first experiments, on a cylindrical journal running in an oil bath, than any since obtained.

THE "BACKUS" GAS ENGINE.

THE accompanying illustrations, Figs. 1, 2, and 3, for which we are indebted to our contemporary, the *American Machinist*, represent a general view and longitudinal and transverse sections respectively of a new gas engine, which will be found to contain some points of interest. As will be seen by the engravings, the frame of the engine is of a modified A form, with the crank-shaft at the top, and there are two cylinders of equal size, which are inclined, the one at the left being the working cylinder, while the one at the right is a pump in which the mixture of gas and air is first received and compressed by the pump piston, after which it passes through a large pipe connecting the two cylinders, and is admitted to the working cylinder by a poppet valve, controlled by the governor. Gas is admitted to the compressing cylinder by a pipe which enters the cover, and air enters through a number of holes which are made in the cover around the pipe, as shown by the end view of this cover at the right of Fig. 3. The air holes are covered by a valve which is opened by atmospheric pressure, and seated by the pressure within the cylinder. The proportions of gas and air are controllable by a valve in the gas supply pipe. Near the working cylinder, and in the large pipe which joins the two cylinders, is a poppet valve, having a stem projecting through a stuffing-box below. This valve is kept seated by a spiral spring, and is lifted to admit the explosive mixture to the cylinder by a lever, which is pivoted to the side of the frame, and receives its motion from an eccentric placed inside the fly-wheel, as shown in section at Fig. 3. This eccentric is made in two parts joined together by a hinge-joint at one side, one of the parts being secured to the end of the hub of the fly-wheel by screws as shown, while the other is free to move upon the hinge-joint to give greater or less eccentricity, its tendency to fly outwards being resisted by a spiral spring.

The amount of eccentricity is controlled by the wedge seen under the eccentric in Fig. 3, and attached to one of the arms of the fly-wheel, and its distance from the centre of the shaft is controlled by the opposing forces of the spiral spring shown behind it, on the one hand, which tends to force it inwards and open the eccentric, while upon the other the centrifugal force of the weight under the spring tends to withdraw the wedge and allow the eccentric to close. A half strap fits in the groove of the eccentric below, from which, by suitable connections, the valve is moved, and admits more or less of the mixture to the cylinder, according to the power required, an explosion taking place at every revolution when necessary.

There is no exhaust valve; near the upper end of the cylinder has a narrow opening or port, which passes entirely around the inside of the cylinder, and connects with the large passage seen, which also extends around the cylinder, and at the top is connected with the exhaust pipe as shown. The piston passes over this port at the end of the stroke, and exhaust takes place. The igniter is seen at the left of the working cylinder (Fig. 1), and is operated by a cam placed on the crank-shaft just inside the belt pulley, shown in Fig. 1. A small jet of gas is kept burning, and a cylindrical valve operates to give communication with the contents of the cylinder at the beginning of the stroke. Provision is made for cooling the cylinder by circulation of water, as shown, and also for thorough lubrication.

It has been found by experiment that the regulation is satisfactory, and there is no trouble in starting this engine. It is built in various sizes by the Backus Water Motor Company, Newark, New Jersey, U.S.A.

THE ANNEALING OF COPPER.

IN an article on the Elmore copper process, in our issue of the 27th February, mention is made of the injury that may result from the exposure of copper to the complicated products of the combustion of gaseous or solid fuel in the process of annealing. In connection with this it is interesting to note that a new process of annealing copper and its alloys has been recently developed in America by Mr. G. Wyckoff Cummins, Ph.D., M.D., whereby copper during annealing is allowed to come in contact neither with products of combustion nor with the air. By this process the annealing is performed in upright annealers or horizontal retorts of cast iron, and the exclusion of furnace gases and air is effected by keeping the annealing vessel continually filled with steam at atmospheric pressure. The steam serves simply as a packing, and is to be considered in no sense as a heating agent. The retort with the contained copper is heated by any desired fuel, while, by present methods, carefully selected fuel must be used to prevent injurious gases from coming in contact with the heated copper.

As is well known, when copper is annealed in the ordinary manner in a muffle, the surface is oxidised to a greater or less extent, and if care be not taken in the heating, the copper is readily "burnt," to use the common expression. Burnt copper is so exceedingly brittle that it can scarcely be bent once at a right angle without breaking. When coarse copper wire is improperly heated in a muffle only the surface is burnt, while the interior

Digitized by Google

THE "BACKUS" GAS ENGINE.

CONSTRUCTED BY THE BACKUS WATER MOTOR COMPANY, NEWARK, NEW JERSEY, U.S.A.

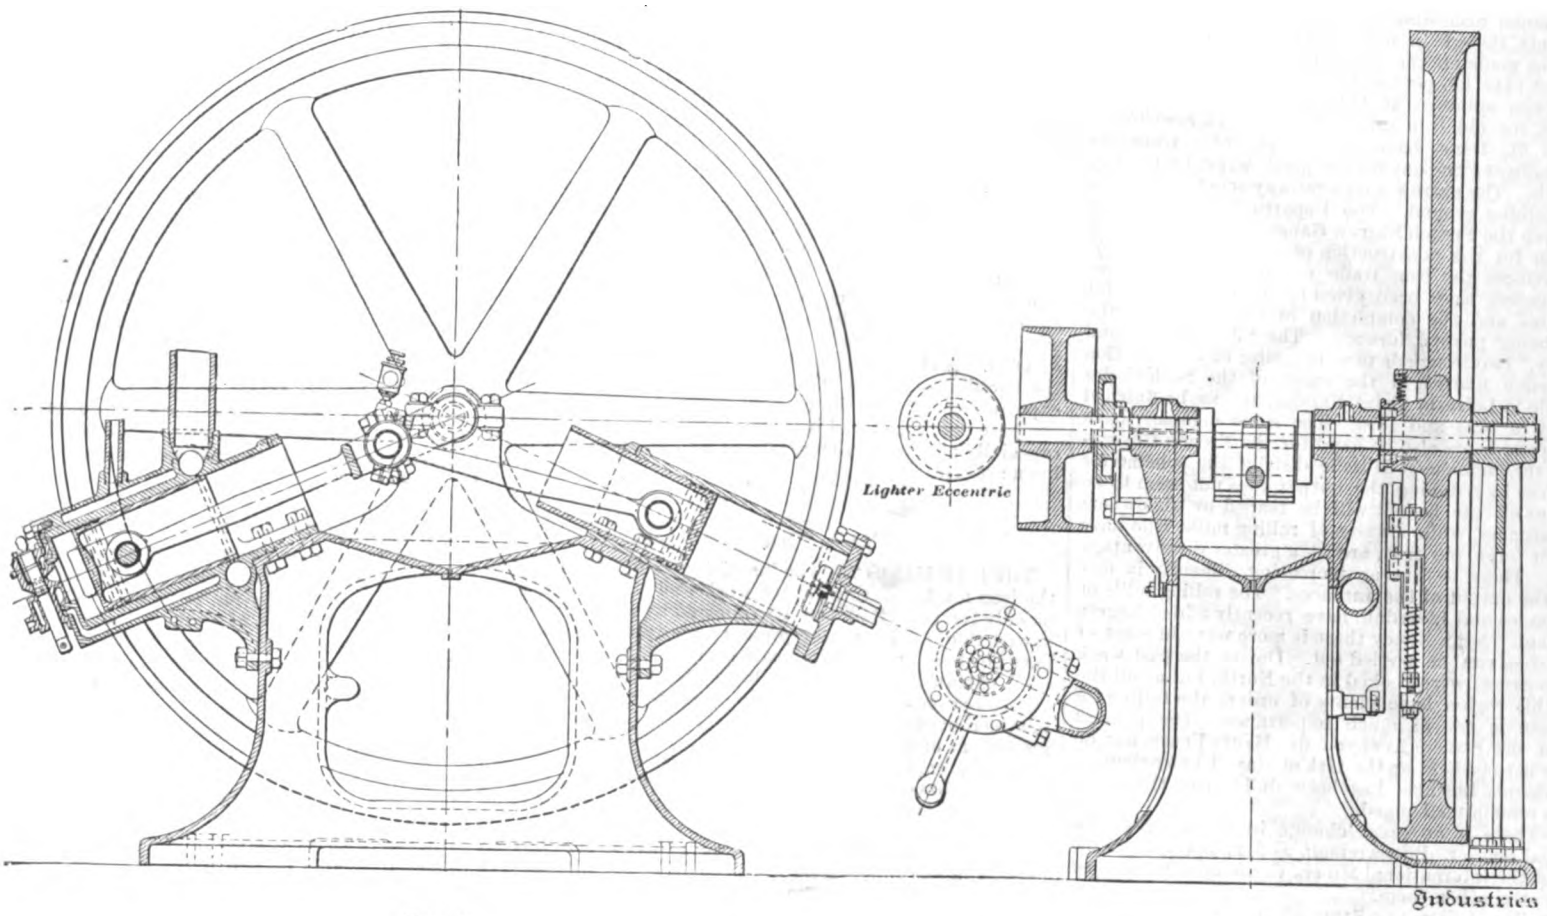

FIG. 2.

FIG. 3.

is damaged to a far less extent. This causes the exterior to crack and split loose from the interior on bending, thus giving the appearance of a brittle copper tube, with a wire neatly fitted into it. Burnt copper possesses decreased electrical conductivity, and it is quite possible to decrease this by 5 or more per cent. by burning copper wire to so slight a degree as scarcely to affect its other physical properties.

Various theories have been advanced to explain what occurs in the burning of copper. Carbon and carbon monoxide are known to combine with copper to the extent of a fraction of 1 per cent., and cause it to have some of the properties of burnt copper, and the presence of its suboxide causes copper to be quite brittle. But by far the most widely accepted view of burning is that the small amount of oxygen usually present in refined copper as oxide of some impurity is removed, and an impurity, such as arsenic, antimony, or lead, is left free to form a brittle alloy with the copper. It is probable that two or more of these reactions may occur simultaneously in the production of burnt copper. That the change is chemical, and not merely physical, is evidenced by the fact that if, by any means, chemical change is prevented ordinary heating will not produce burnt copper. The addition of oxygen, or the removal of the trace of oxygen usually present in even the highest grades of refined copper, causes copper so treated to suffer a deterioration of most of its desirable properties—viz., malleability, ductility, tensile strength, and electrical conductivity. It is apparent, therefore, that a perfect annealing process will allow neither oxidation nor deoxidation of copper to occur. Steam has no chemical action on copper at any temperature below its melting point, so that copper annealed in an atmosphere of steam does not suffer the loss of any desirable property. It has been found that the purer forms of copper are far less liable to be damaged during annealing than samples containing even a trace of impurity. When annealed in steam, this difference is not apparent. This enables a cheaper grade of copper to be used for purposes to which only the highest grades of refined copper have hitherto been suitable. The steam method of annealing copper, in addition, gives a perfectly bright product with no loss of metal as scale, and no necessity for "pickling" before further working, while the metal may be heated sufficiently to make it "dead soft" without danger of burning. The steam annealing process is, we understand, less expensive than the present method.

THE ATLANTIC RACE.

IN our issue of the 27th ult. we considered some of the probable characteristics of "The Ships of the Future," looking chiefly at the subject from the point of view of construction. There can be little doubt that the race across the Atlantic will be one of the most important factors in the production of the first-class passenger ship of the future, and in the development of its construction and increase of its speed. Since the first of the Atlantic "greyhounds" was built, and accomplished the voyage from Liverpool to New York in seven days, shipbuilders have always kept in view the problem which they were certain would soon be placed before them, of designing and building ships which would accomplish the voyage more quickly, and from time to time various designs were reported to have been made which were intended to be great advances on all that preceded them. But the British shipowner is naturally very cautious, and rightly so, and although each succeeding ship has been to a certain extent an improvement on all those which preceded it, there has been no great departure from ordinary practice. The following table shows the advance which has been made in size and power since the "Arizona" was launched:—

	Length in Feet.	Beam in Feet.	I.H.P.
Arizona	465	46	6,000
Servia	530	52	10,500
Alaska	520	50	10,500
Aurania	470	57	10,000
Umbria	520	57	12,500
Etruria	520	57	12,500
City of New York	560	63	18,000
Teutonic	582	57	16,000
City of Paris	560	63	18,000
Majestic	582	57	16,000

The newer of these are "six day" boats. When one of the earlier "greyhounds" was launched Sir William Pearce stated that, although these ships were great advances on their predecessors, he believed that the voyage could be made in very much less time, and he hoped that the owners of the leading lines would see it to be to their advantage to provide vessels of the newest style, each a distinct advance so far as speed was concerned on anything then afloat. This is precisely what has happened, but, as we have stated, in a very cautious and tentative manner, for the money invested in a first-class Atlantic steamer is not a trifle with which hasty and ill-considered experiments may be made.

But now it seems as if a greater step is about to be taken, and that both in this country and in America attempts are to be made to produce "five day" boats. The new Cunard liners and the vessels to be built by the Barrow Company are "dark horses," as no particulars have as yet been made public regarding them beyond the fact that they are to surpass their predecessors in size and speed. In America, however, the same reticence has not been kept with regard to the intentions, or rather the wishes, of the projectors of the lines which are beginning to spring up under the joint influence of the subsidy and the McKinley Act, but it is doubtful whether they have considered all the factors of the problem and the difficulties to be overcome. A "five days'" voyage means an average speed of 25 knots an hour, which is by far the largest step in advance which has yet been taken, and which will consequently require a very great increase in power. If the vessel were made an express boat, it would require to have engines indicating at least 25,000 horse-power, while, if it carry the usual amount of cargo for a first-class passenger ship, it will require about 5,000 horse-power more. The proper policy, in our opinion, to pursue in this matter is for shipowners to give up the idea of carrying cargo in these boats, so that they may be able to start on the return voyage after having sufficient time to coal and take in new passengers, but without the delay attendant on taking in cargo. The cost of such vessels would be very great, and, in order that they may be commercially successful, time must be economised to the very greatest extent possible. With regard to the construction of the hull and the engines, it is probable that there would not be much variation from those at present in use, although weight would be economised as much as possible, both in the design and by the greater use of alloys. From the paper read recently by Mr. Biles before the Institution of Naval Architects, we learn that American shipbuilders and engineers have made very great progress during late years, but we doubt if they are able to construct successfully such ships as we have been considering. To say the least, it would be a very risky experiment. The lead must, in any case, be taken by the managers of the British yards, and, having regard to recent progress we look forward with confidence to the near future, in the expectation of seeing vessels which will be capable of making the Atlantic passage in five days.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 21st April, 1891.

The Iron Market.—Prices during the past week have been maintained according to the tariff agreed upon by the merchants, though in most instances some reduction has had to be made on the quotations of 136s. 6d. per ton for bars, and 144s. 6d. per ton for joists. Orders for castings have been obtained at 114s. per ton, and there is a fair demand for old iron rails at 80s. 6d. La Société des Ateliers de St. Denis have secured an order from the Northern Railway Company for 600 goods waggons, to carry 15 tons each. The narrow gauge railway scheme seems to be slowly gaining ground. The Department of la Creuse has just given the French Narrow Gauge Railway Company a concession for the construction of 250 miles of railway. In the provinces the iron trade continues good. Some important orders have been given by the Government for armour plates, and the completion of vessels now on the stocks is being pushed forward. The "Jemmapes" and the "Valmy," two ironclads now in course of construction for the French marine, in the yards of the Société des Chantiers de la Loire at Saint-Nazaire, are to be finished respectively in 1893 and 1894. The same company have several torpedo boats also on hand for the French Government. In the Meurthe-et-Moselle district the scheme for raising prices by reducing the output does not seem to be a success, as all the benefit will be reaped by the owners of blast furnaces, while owners of rolling mills, who have to buy their forge pig iron, are at a greater disadvantage than ever. There is thus an increasing difficulty in disposing of the output of the furnaces. The rolling mills of Champigneules and Liverdun have recently added largely to their plant. Near Nancy there is more work in some of the shops than can be carried out. During the past week but few contracts were booked in the North, but as all the works in this region have plenty of orders the falling off in this case is not of much importance. The general meeting of the Scciété Anonyme des Hauts Fourneaux de Maubeuge is to be held on the 11th of May at Valenciennes. In the Ardennes business has been dull during the week, but prices remain unchanged.

Coal.—There is no great change in the state of the French coal market. Prices remain as firm as ever, and the decision of the International Miners' Conference has tended to further strengthen them.

Copper, Tin, Lead, and Zinc.—The copper market has not been so firm during the past week. Best Chilian bars were quoted at £57; ordinary Chilian bars at £55 5s.; and best selected at £59 5s. the ton. Tin has decreased slightly in value: Banca is at £98 10s., Billiton £96 5s., and Cornwall £100 12s. per ton. Lead is quoted at £13s. 5s., and zinc (Silesian) at £24 10s. per ton.

The Eiffel Pressure Column.—The "Manomètre" recently placed on the Eiffel Tower, being 300 metres in length, is capable of measuring a pressure of nearly 400 atmospheres. The tube, which is of mild steel, and is 4 millimetres in internal diameter, has been rolled out of old Chassepot rifle barrels. On this tube, at intervals, are placed cocks which lead into vertical graduated glass tubes, whose upper ends are connected by indiarubber joints with another down pipe leading to the receptacle for the mercury at the base of the tower, so that if one of the cocks should by accident be left open the mercury will not be wasted. M. Louis Cailletet, Member of the Institute, under whose direction the installation was made, hopes to be able to carry out some interesting experiments, which hitherto the want of a sufficiently long column has rendered impossible.

New Cotton Mill.—Messrs. E. & P. Sée, of Lille, have received the contract for the construction of a new cotton spinning mill at Euschedé. The mill will be built after the most modern designs, and will contain 25,000 spindles.

BERLIN, 20th April, 1891.

The Coal Market.—The condition of the coal market is unsatisfactory. The demand for coals for immediate delivery has considerably diminished, and there is a quieter development of traffic on the railways after the strain of the past few weeks. Orders for yearly supplies of coal have also largely decreased. The production fails to keep pace with the demand. It is expected, however, that the output will be increased by 10 per cent. if there are no further strikes in the coal districts, and the present deficiency of coal would then cease to exist. Some thick and productive seams of coal have been discovered between Bayreuth and Neuenmarkt in Bavaria. The coal, which has a rich black fracture, is an excellent pitch coal, and is not of inferior quality to the coal of Saxony or Stockheim.

Potassium Salts.—The Goslar-in-Harz Deep Boring Company has made some borings for potassium salts at Westerlieden, in Brunswick. The stratum has been proved to a depth of 4 metres, and the borings are to be continued, as further discoveries are expected.

The "Kosmos" Steamship Company.—This company has received a concession for the establishment of a regular service of steamers between Germany and Guatemala. The "Kosmos" Company will have a fleet of six vessels, of 1,500 tons each, which will touch at various European and American ports. The principal ports of call in Europe are London, Bremen, and Hamburg. The Government of Guatemala will pay a subsidy of $1,000 for every steamer which touches at the ports of the Republic in accordance with the terms of the concession, and the vessels are to be exempted from all taxes and harbour dues. Similar agreements have been made between the "Kosmos" Company and the Governments of Salvador, Nicaragua, and Costa Rica.

Textile Industries.—The weaving industry, which at one time was in a flourishing condition, has fallen off to an extent which is without parallel in the development of the industry. This falling off is indicated by the fact that the export from the Chemnitz district alone to the United States, which is the chief market for Saxon goods, shows a decrease of 7,122,792 marks. This decrease is almost entirely to be accounted for by the decreased orders for woven goods occasioned by the McKinley Act. The Chemnitz district has at present large stocks of staple articles; for the better class of goods there is very little demand, and cheaper sorts have been taken off the market for some months past. The prices of staple articles have fallen enormously. The McKinley Act is affecting other districts also which are employed in textile industries. The export trade from the district of Munich shows a large decrease in the first quarter of this year as compared with last year, the figures being £37,543, as compared with £54,849. A similar decrease is recorded in the district of the Dresden consulate and in the agency of Zittau. The exports amounted in the first quarter to £64,334 7s. 6d., as compared with £103,373 in the previous year. The decrease especially affects woollen goods, as well as linen and half-linen articles.

VIENNA, 20th April, 1891.

The Iron Market.—The inactivity which characterised the iron market during Easter week was thought likely to be only temporary, and to be followed by a period of renewed vigour. Up to the present time these expectations have not been realised, for trade is still confined within the same narrow limits, and sales have been unimportant, with the exception of iron for building purposes. Both wholesale merchants and consumers appear to be waiting for a settlement of the relations between Austria and Germany, since the continued introduction of wrought iron from Germany lowers prices, and consumers are compelled to adopt an expectant attitude. A rise in the market cannot be expected until the commercial treaty with Germany has been concluded. The assurance of peace, which was expressed in the Imperial address, should be advantageous to trade, and ought to lead to important results. During the past week large orders have been given by the city of Vienna for cast iron pipes to the value of 80,000fl.

The Coal Market.—The coal market still continues very lively, and this is shown by the large quantity despatched to the Elbe. In the week before last the Dux-Bodenbach line forwarded 46,752 tons of coal, and the Prague Dux line 20,622 tons. The Bremer Lloyd line of steamers, which has been bringing coals from America, has caused some uneasiness in the coal market here. A similar plan has been already tried by Austrian shipping companies, and was found to be effective against the syndicates.

Electrical Engineering.—The number of electrical installations in this kingdom is continually increasing. A new installation has been erected at Thexl, in Styria, by Messrs. Kremenitzky, Mayer, & Co. (The Brush Company), consisting of 4,000 incandescent lamps, and a smaller installation at the salt works at Ebensee. Water power is utilised in this case, and the salt works, baths, manufactories, and hotels, as well as the chief square, are lighted up by incandescent and arc lights. Electric lighting is making steady progress in Vienna. The International Electricity Company now supplies 15,000 lamps of 16 normal c.p. each from its central station, and it seems probable that this will be enlarged so as to supply 20,000 lamps next year. The central station belonging to this company at Fiume, which is used for the distribution of power by an alternating current, is also to be extended. Two motors of 12 h.p. each are being erected, and the elevators are being provided with electric light. The telephone system in Austria has just received an important extension by the laying of a line from Vienna to Trieste. The two provincial cities Graz and Laibach are already in the circuit, and the lines from Fiume and Görz are to be joined to the system.

BRUSSELS, 21st April, 1891.

The Iron Market.—The market shows little signs of briskness. Old orders are being worked off and there is a scarcity of new orders. Steel is being used increasingly in the place of iron, and Belgium seems likely to lose also her special trade in joists. Prices are weak, in spite of the action of the syndicate and the present quotations for raw material. The prospect of business in our centres of manufacture is rather gloomy, the home demand being very small, and competition for the foreign trade being keen.—The Liége Water Pipes Company, which has an order for 25 miles of pipes for Caraccas, is sending its first shipment by the steamer "Walford." The engineer in charge of the work has already started for Caraccas, and a large number of workmen specially qualified for the work are about to proceed thither. The plans of a direct railway from Antwerp to Brussels have been already approved by M. de Bruyn, the Minister.

The Coal Market.—The award of contracts on the 7th inst. has not thrown any light on the condition of the market, the quotations being regarded as abnormal. It is possible also that the Government will not ratify the award. Ironmasters prefer not to make arrangements for a longer period than three months in the expectation of a drop in prices. There is a renewed demand for patent fuel for Germany.

The Glass Trade.—A large quantity of Belgian glass has lately been objected to by buyers in the United States, and numerous urgent complaints have been addressed to the manufacturers. Buyers complain that the glass is burnt, and that the kilns are generally defective. This circumstance should be noted, as its consequences may be serious. Complaints are also made of the uneven cutting of Belgian glass. If our manufacturers do not wish to lose an important market, they should at once pay attention to their method of manufacture. Prices remain almost unchanged, and there is no large quantity of stocks. The demand is slowly improving, and an excellent season is expected. Much business is done from hand to hand.

Chambers of Commerce.—Most of the Chambers of Commerce have received notices from the Government to meet on the 3rd and 10th of next month. They have been requested to furnish information as to salaries, the price of food stuffs, and working expenses, in view of a discussion which has arisen with reference to commercial treaties. If France should carry out a Protectionist policy, it is proposed to counteract its effects by placing prohibitive tariffs on imports from France.

DÜSSELDORF, 21st April, 1891.

The Iron and Steel Market.—The general tone of the iron market is not encouraging, and consumption is decreasing in almost all branches. There is much complaint as to the state of trade in the Siegen district. The prices of the spathic ore have again been reduced, and all those mines which have no rich and easy workable deposits, or which are not situated favourably in regard to transport, have been laid idle. In spite of the low price of iron ore the cost of producing pig iron is very high, as coke is not sold below 12s. 9d. per ton, and there is a considerable freight charged for transport to Siegen. Many efforts have been made to form syndicates, but, with the exception of the Spiegeleisen Syndicate, as yet without success. On the 18th inst. a meeting was held for the purpose of forming a general pig iron syndicate in Siegen, but will probably have little practical result.

The Coal Market.—The coal market continues very brisk. Some partial strikes at the Sellerbeck and Eintracht pit, where about 500 miners have ceased to work, will rather improve the general situation. The public awards in Cologne and Magdeburg have shown that the Westphalian colliery owners are adhering steadily to the scale of prices, and there are really only a few works which have not entered into the various coal syndicates at Dortmund Bochum, or Essen. Consumers are still eager to complete their stores, and the daily railway transportation is about 10,500 cars, of 10 tons each.

Aluminium.—The works at Hemelingen, near Bremen, which were employed in the manufacture of aluminium and magnesium, have now ceased to manufacture the first-named metal. They were using a modified Graetzel-Castnez process, but the cost of working was too high, and they could not compete with the large plant at Neuhausen-on-the-Rhine, which works the electrolytic process and utilises the Schaffhausen water-power. This company has reduced its prices to about a third of what they were a year ago. Pure aluminium (from 98 to 99¾ per cent.) is quoted at 12s. 3d., and second quality (from 92 to 98 per cent.) at 10s. 4d. per kilogramme. Aluminium-bronze is at from 2s. 2d. to 3s. 2d., and aluminium-brass from 1s. 6d. to 1s. 8d. The company also manufactures castings, plates, wires, and tubes.

AMSTERDAM, 20th April, 1891.

Steamboat Companies.—It appears from the directors' report of the Rotterdam Lloyd Steam Navigation Company that its nine boats performed in 1890, 23 journeys between Rotterdam and Java. With the aid of two steamers, chartered from the Rotterdam Steam Navigation Company, a fortnightly service with Java was kept up. The said two steamers will be replaced by others, now being built at the yards of the Schelde Company in Flushing, the first thereof being ready in May, and the second in September of the present year. The directors remind the shareholders that the new mail contract with the Government fell through, and will require fresh negotiations. The profits last year amounted to £57,720, of which £22,408 were written off for depreciation. Deducting further payments, there remained £23,513 available for dividend, distributed at the rate of 7 per cent. on a capital of £330,000. The report of the directors of the Netherland-American Steam Navigation Company of Rotterdam confirms the preliminary announcement that the service yielded bad results in 1890. The usual amount being written off, the accounts close with a debt of £5,451, so that there is no dividend this year. The South American branch gave a heavy loss, owing to the crisis in the River Plate, which led to a serious shrinkage of the goods traffic, whilst the stoppage of assisted passages to emigrants by the Argentine Government affected the passenger traffic. After nine journeys, the company's boats

Digitized by Google

were compelled to stop running to Buenos Ayres. The 59 journeys to and from New York yielded a fair profit in many instances; whilst in others there was a loss. The rise in the price of coals and of wages had a bad effect upon the results of the service in 1890. Fortunately, the company was spared any serious loss in ships last year. The Board is still of the opinion that the causes of depression in the South American trade are only temporary, and that there is yet a future for the company's operations in that direction. In order to find employment for the steamers that were running to South America, the directors propose opening shortly a new line to and from Baltimore.

THE ROYAL INSTITUTE OF CIVIL ENGINEERS.—The members at their last meeting approved the resolution of the Committee to invite the Société des Ingénieurs Civils in Paris to be their guests at the Hague for a few days in August and September next.

NEW COMPANY.—An important new company in Amsterdam has issued its prospectus—viz., the Commercial and Industrial Company of Curaçoa, formed with a capital of £41,666, in shares, and bonds, in equal moieties, to acquire wharves and other properties near the harbour of the capital of the island. This harbour is one of the best in the West Indies, and was visited by no less than 1,208 ships in 1889. Besides four wharves, the properties comprise an hotel, dwelling-houses, and various warehouses and sheds, the whole covering an area of 32,520 square metres. It is proposed to develop this estate and to build new jetties.

A TRAMCAR STARTER.—The invention of Mr. S. L. Huiser, for aiding the efforts of horses in bringing omnibuses, tramcars, and other heavy vehicles into motion, is kept a secret, but the experiments on the tramway at Haarlem appear to have been very successful. The apparatus, which weighs 100 kilogrammes, is worked by the driver with his foot, and by its use an empty tramcar, weighing 1,700 kilogrammes, could be easily moved by a child. Mr. Huiser says that the apparatus, manufactured wholesale, would only cost about £8 7s. each.

STOCKHOLM, 18TH APRIL, 1891.

THE PEAT INDUSTRY.—The Hörda estate at Annsberga has been taken over by an English syndicate under the management of Mr. A. R. Billit. The vast deposits of peat will now be utilised, and the manufacture of "artificial coal" commenced.

NEW HARBOUR AT GEFLE.—The Corporation of Gefle have decided to extend the harbour, for which purpose the Frederiksskaus will be purchased. The new works are expected to entail an expenditure of £37,462.

INSPECTION OF FACTORIES.—The official inspection of factories, which was introduced a year or two ago, is a much-needed institution, as there exists in some places a very unsatisfactory state of affairs. An illustration of this statement has just been afforded by the inspection of the Korndal Works, in the Gothenburg district. The inspector has, in his report, insisted upon the complete closing of the works until the boilers have been thoroughly examined by an expert. During the last twelve months six men lost their lives while at work, and twenty-six have suffered more or less severe injuries. The pressure gauges are out of order, and one safety valve was loaded with double weight. Several belts and pulleys are dangerous, arrangements for cooling and signalling faulty, and the elevators are not protected. It is evident, therefore, that the appointment of State factory inspectors with full authority was absolutely necessary.

SERIOUS STRIKE.—The strike, which has been going on for some time at the Kallmora Mine, has now assumed large dimensions, and from one to two thousand men are out on strike. This strike affects about twenty mines in the important Norberg mining district. The cause of the strike is the dispute at the Kallmora Mine, and it is in order to gain their point in that dispute that so many men have determined to strike. A conference will shortly take place between delegates of the masters and the men.

CHRISTIANIA, 18TH APRIL, 1891.

NEW WARSHIP.—The new gunboat "Viking," which was recently launched from the Horten Dockyard, will be the strongest ship in the Norwegian navy. It is built of steel, and the principal dimensions are:—Length, 62 metres; breadth, 9·3 metres; and the speed will be 15 knots. The cost is about £72,000. The hull is protected by an armour deck of 1⅛in. in thickness. The "Viking" is to carry two 15cm. guns, four quick-firing 65mm. guns, and six 37mm. machine guns. The ammunition is placed in two compartments, fore and aft, and there are three appliances for firing torpedoes. The "Viking" will have two propellers, each worked by independent horizontal triple-expansion engines, separated by a water-tight bulkhead, and with an aggregate power of 2,000 i.h.p.

MILK PRESERVING.—The milk preserving manufactory at Toten is now nearly completed. The installation has, however, proved more expensive than at first was estimated, and it will therefore be necessary to increase the share capital.

THE ELECTRIC LIGHT AT HAMMERFEST.—The electric light at Hammerfest, the northernmost town in Europe, is giving much satisfaction. The installation is to be extended, so as to comprise 550 incandescent lamps for house use instead of 300.

THE NATIONAL EXHIBITION AT SKIEN.—The works in connection with the Skien Exhibition are now being rapidly proceeded with, and the main building will be ready about June 1st. The Exhibition will comprise six sections, of which the first is the industrial one, and the fifth comprises agricultural machinery and implements.

MADRID, 20TH APRIL, 1891.

BILBAO AND PORTUGALETE RAILWAY.—At a general meeting of the shareholders held recently a dividend of 16 per cent. was announced. The traffic is steadily increasing, and the line is to be doubled. The credit of the company being very good, no new shares or debentures are to be issued for this purpose, but the money is to be raised by means of bills.

THE VISCAYA IRON WORKS.—The Viscaya Iron and Steel Works Company have made a profit of £52,000 during the past year; £38,000 has been deducted for depreciation and interest on debentures, and there is a net profit of £14.000, out of which a dividend of 6 per cent. is to be paid. A large quantity of puddled iron is still imported into the country, and the company have, therefore, determined to erect puddling furnaces. They are also erecting a Roberts converter for steel making.

SCHOOL OF ARTS AND MANUFACTURES.—About seven years ago a dispute arose between the contractor and the Administration with regard to the extensive building which was being erected for a school of arts and manufactures in Madrid. The work has now been resumed, and is to be pushed forward as rapidly as possible.

THE EIGHT HOURS MOVEMENT IN SPAIN.—Some anxiety is felt as to the manifestation which is announced to take place on the 1st of May. The labourers generally are in favour of an eight hours day, but they have little hope of obtaining such a law, and say that even if such a law was passed it would be inoperative except in the case of labourers paid by the Government or official authorities. In no other district, except Catalonia, have the workmen any serious hope of improving their condition, and they have little expectation that the meetings will have any practical result. The Government has decided not to allow any open air meetings, as they interfere with the circulation of traffic.

CULTIVATION OF CHINA GRASS.—An attempt to cultivate China grass is to be made on a large island, "La Isla Menor," on the shores of the River Guadalquivir. It is intended to plant 5,000 acres with the grass, and to erect a mill for the production of goods from the fibre. The scheme is to be carried out with English capital, and 100 acres are to be planted at first. A capital of £6,000 has been subscribed in order to make experiments, one-half of which has been furnished by the proprietor of the land, and the other half by an English capitalist, who represents a syndicate. The scheme excites much interest in Seville, as that city would be greatly benefited by the accomplishment of the project.

ROME, 20TH APRIL, 1891.

SHIPBUILDING.—On the 15th inst. Messrs. Gio. Ansaldo & Co. launched from their yard at Sestri Ponente a steel screw steamer of 4,200 tons, with triple-expansion engines of 1,350 indicated horse-power. This is the largest steamer that has been made entirely in Italy, and it has been named "Giulio Cesare." Another steamer will be launched for the same owner two months hence, and will be called "Michele Lazzaroni." The owner is Mr. Mazzino, who will thus have a fleet of four fine steamers, which will be used for long voyages, and especially for the Indian trade.

DUTY ON PETROLEUM.—On the 14th inst. Mr. Colombo, Minister of Finances, presented to Parliament a Bill relating to the Duties on Petroleum. The duty on paraffin oil is to be maintained at 37s. per 100 kilogs. A duty of 6s. 4d. per 100 kilogs. has been proposed on heavy oils, provided they are not adapted to be used for lighting purposes in ordinary lamps, whether alone or mixed. The refinement of oils can only be carried on with the permission of the Government, With regard to oils imported from abroad, the rules for the refinement are to be established by a Royal decree. With regard to petroleum imported in tin vessels, these will be allowed for at the rate of 12·50 per cent. The Government is also intending to create a monopoly of matches, as in France.

NEW YORK, 11TH APRIL, 1891.

ELECTRIC TRANSMISSION OF POWER.—A novel electric plant is being installed at Telluride, Colo., by the Gold King Milling and Mining Company. The gold ore at this place is abundant, but of such low grade that the operating expenses until recently were barely covered. The machinery was driven by steam engines, but fuel is now scarce, and the manager, Mr. L. L. Nunn, recently decided to utilise the water power in the vicinity. A dam was built across the San Miguel River, which falls 500ft. in less than a mile at this place, and from the headgate the water is taken through a pipe 4,000ft. long, gradually decreasing in diameter from 20in. to 12in., to the power station, where it is delivered to two 6ft. Pelton wheels. Westinghouse machinery is used, and the loss in transmission between generator and motor, over a 2½ mile circuit, is said to be barely 5 per cent.

NOVEL METHOD OF RUNNING ELECTRIC CARS.—At Seattle, Wash., there is about to be put into operation a novel method of running electric cars up steep inclines. The electric railway there has a very steep incline about 800ft. long, and it has been found that the motors on the cars are inadequate to surmount the hill. To correct the difficulty a small conduit about 2ft. square is constructed, and in this is to run a small car as a counter-balance. Two ropes will be attached to the counter-balance car at the top. When an ordinary car is attached to the rope the counter-balance car runs down the hill, but when the car reaches the top of the hill it runs down on the other side, and, aided by the motor, it pulls up the counter-balance car, which is now ready to bring up another car.

A NOVEL ELECTRIC ELEVATOR.—The Keystone Electric Company, of Erie, Pa., have just completed a novel and ingenious electric elevator. The details of the combination have all been worked out in the best and simplest manner, and possess many new and advantageous features. The operation is very perfect, the motor being entirely free from sparking, heating, or other undesirable features, which are a constant source of trouble when they exist. The motor drives the elevator by means of a belt from the pulley on the winding shaft to that of the motor, which only runs during the time that the platform is moving.

NEW OIL SEPARATOR.—Mr. C. I. Stock, of the North-West Natural Gas Company, Ohio, has recently brought out a new automatic separator, which is designed to separate oil or other fluids from gas. The separator is attached to the line that leads from the well, and is so constructed that no liquid passes in the gas line. It will work readily on any pressure from 1lb. to 500lb. Several of the separators are in use in the Dayton field; one by the City of Tiffin, at Bairdstown, and several in Hancock county. The one at Bairdstown was timed recently, when it separated and threw out 55 gallons of oil in 30 minutes.

NEW WIRE GUN.—The new wire gun invented by John Hamilton Brown, of New York, was tested recently at Fort Wadsworth, Staten Island, in the presence of army and navy officers. The gun withstood pressures respectively of 41,500lb. and 60,000lb.

NEW LIGHTHOUSE.—The Lighthouse Board have awarded the contract for the construction of a composite lightship for service at the Columbia River Bar to the Union Iron Works, of Francisco. The Board have awarded the contract for the construction of three lightships for service on Lake Michigan to the Craig Shipbuilding Company, of Toledo, Ohio.

PHILADELPHIA, 10TH APRIL, 1891.

THE STRIKE IN THE COKE REGIONS.—During the past week there has been much trouble in the coke regions, and the strike is as yet far from being settled. The men had become so riotous last week that it was necessary to call in the militia, and in a conflict which ensued between the latter and the men a number of Hungarian workmen were killed. The strikers are intensely excited over this affair, and more trouble is anticipated. The masters are now having the ten-day notices served on the strikers who occupy houses belonging to the company. It is stated that they are preparing to import men, and are, therefore, anxious to obtain possession of their houses. It is as yet impossible to predict how the strike will terminate, but it is expected that some decisive action will be taken before the end of the week.

TROUBLE AT THE PENCOYD IRON WORKS.—It has always been the custom at the Pencoyd Iron Works for the company and the employés to fix a scale on April 1st of each year, which would govern the wages during the ensuing year. This year the men have refused to adopt the firm's scale, and wanted the latter to accept that of the Amalgamated Association of Ironworkers. The two scales are practically the same, except that the firm's scale is a sliding one, while the association's is a fixed scale. The firm has refused to acknowledge the above association exclusively, and has denied the right of outside interference. As a consequence, the furnaces have been blown out since the 6th inst., and 200 puddlers are now idle. The finishing department has now also closed, so that the works have practically shut down. The men are perfectly quiet, and no violence is anticipated.

THE GUNBOAT "BENNINGTON."—According to the statement of the contractor, Mr. U. F. Palmer, the "Bennington" has, after several failures to develop the required horse-power, undergone a successful trial. The report of the last trial has not yet been received at the Navy Department, but the contractor's request that the vessel be received at the Brooklyn Navy Yard has been granted by the Navy Department. It is stated that the engines developed 3,450 h.p., which exceeds the requirements by 50 h.p., which, if true, will earn for the vessel a small premium.

THE WORLD'S FAIR.—The site is already being prepared for the buildings of the World's Columbian Exposition, and from the present outlook there seems to be no doubt that the work will go on satisfactorily. The finances are better than was expected. The popular subscription is £1,100,000, and the city gave £1,000,000, the Government's appropriation is £500,000, and the State appropriations are expected to amount to £800,000. There are to be nine main buildings, which will cover a total of 110¾ acres, which is exclusive of the State and private buildings. The largest building will be that of the manufactures and liberal arts, and will measure 800ft. by 1,700ft. It is also proposed to erect a gigantic tower, which will be 100ft. higher than the Eiffel Tower. The ceremonies of dedication will be held on October 12th, 1892, in order to preserve the historical feature of the commemoration of the discovery of America. The formal opening of the fair will take place on May 1st, 1893.

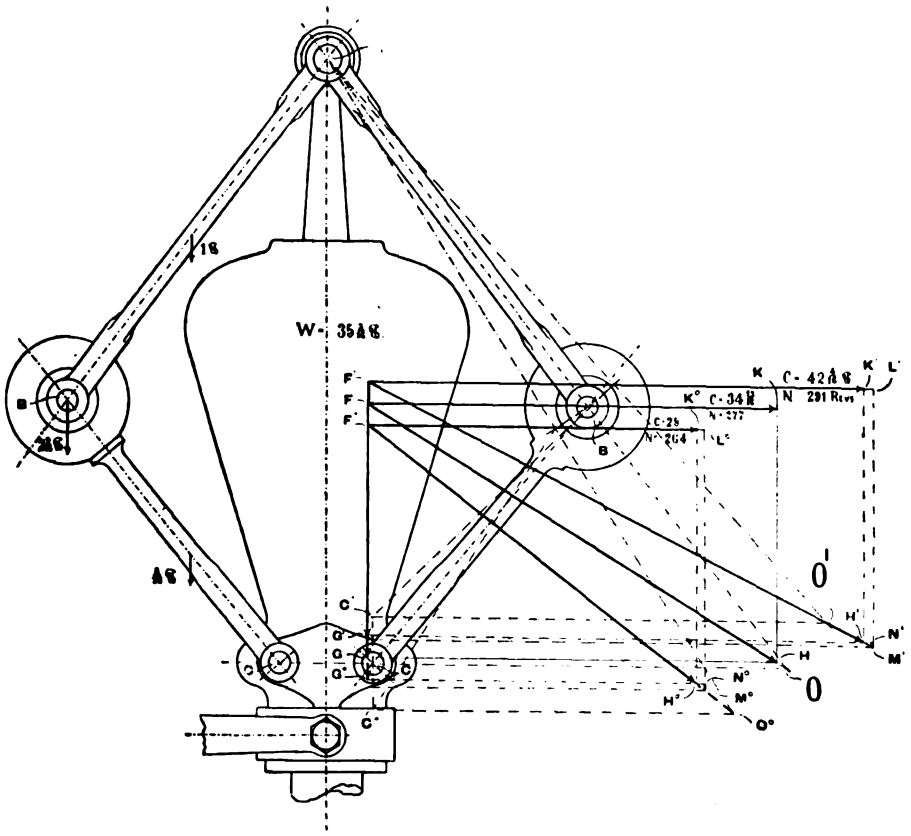
STEAM ENGINE GOVERNORS.



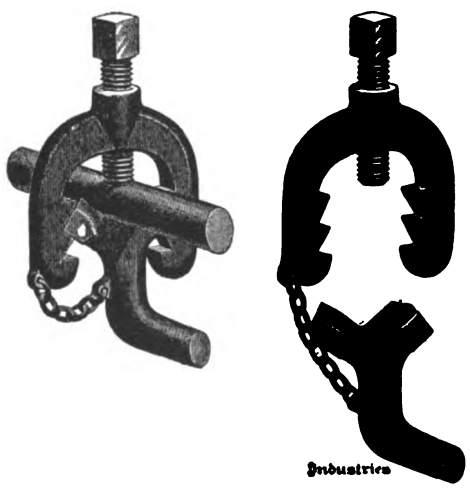


FIG. 1.—THE PORTER GOVERNOR.

A NOVEL LATHE DOG.

THE accompanying illustrations represent the "Indispensable" lathe dog, which can be attached to work resting in the centres of a lathe. The appliance is very simple, and will be readily understood from the illustrations, which are taken from our contemporary, the

Electrical Engineer, of New York. The dogs are forged from bar steel, and have set screws of similar material. They are made in four sizes, the smallest embracing from ¼in. to 1in., and the largest from 1in. to 3½in. The "Indispensable" Lathe Dog Company, of 1,209, Buttonwood Street, Philadelphia, U.S.A., are the makers.

STEAM ENGINE GOVERNORS.*

IN nearly all applications of the steam engine for manufacturing purposes uniformity of speed is a matter of primary importance to ensure a satisfactory product, and since an engine is usually employed to drive a great variety of machinery, any of which may be put into or out of action at any time, it becomes necessary to provide means for automatically regulating the power developed according to the work to be done at any moment, so as to maintain the speed constant or nearly so.

This object is effected by a governor, which serves to regulate the *pressure* or *volume* of steam admitted to the engine, so as to maintain a nearly constant speed. A governor can do no more than regulatate the *mean* speed of the engine, because the steam is only admitted to the engine periodically—*i.e.*, generally twice in every revolution, and the governor can only come into action at corresponding times, whilst it is the duty of the fly-wheel to equalise the speed between the periodic admissions of steam. The primary condition, therefore, of a uniform speed is that the fly-wheel must be sufficiently heavy to take up the variations of *load* and *power* in a revolution without any perceptible variation of speed, and it is the function of the governor to regulate the power in accordance with the more permanent variations in the load.

For the invention of the first steam engine governor we are said to be indebted to the same Watt to whose genius we owe the conception of nearly all the vital inventions connected with the steam engine, even as we know it at the present day, and although the steam engine governor—like many of Watt's productions—has been greatly improved since its invention, chiefly to meet the more exacting requirements of modern manufactures, yet the principle of Watt's governor still stands unassailed, and a very large proportion of the engines which are at work today are fitted with the identical governor invented by Watt.

The Watt governor—which, of course, is familiar to the members—consists essentially of a pair of rotating pendulums connected with the throttle valve or other regulator. Neglecting the weight of the arms, each revolving ball is in equilibrium under the weight of the ball W (Fig. 2), its centrifugal force C and the tension T in the arm, and since we know the value and direction of W, also the direction of C and T, we can at once determine the value in pounds of C by the aid of the parallelogram of forces. If h = vertical height from the plane of revolution to the point of suspension, in inches, and N = number of revolutions per minute, we then obtain $h = (188{\cdot}2/N)^2$. The altitude of the cone of revolution of a Watt governor, therefore, depends solely upon the number of revolutions per minute, and it is quite independent of the weight of the balls and of the length of the arms. Starting from a position of rest, the balls will commence to fly out when the speed begins to exceed that corresponding to the altitude of the governor at rest, and the altitude will vary inversely to the square of the speed of the governor. For most practical purposes the movement of the balls in a Watt governor corresponding to a certain variation of speed is insufficient, and the governor is therefore said not to be sufficiently sensitive. If in this governor we increase the effect of the weight without at the same time augmenting the centrifugal force, then a smaller proportionate variation of speed will be required to produce a certain variation of altitude, and the sensitiveness of the governor is therefore increased. This can be done by applying a weight or spring to the muff, and we have one example of this in the well-known "Porter" governor. Thus if we apply to the muff a weight equivalent to W^1 then the altitude for any given speed is increased in the ratio of $W^1 + W/W$, and the variation of altitude corresponding to any change of speed is increased in the same proportion.

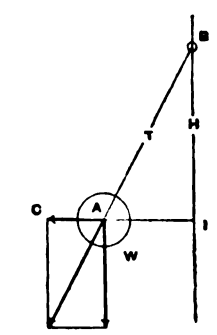

FIG. 2.

By increasing the weight of W^1 in proportion to W, the sensitiveness of this governor can be increased to any desired extent, but manifestly the governor cannot be made absolutely isochronous. Any increase of sensitiveness will also involve a corresponding increase of speed.

Fig. 1 shows a Porter governor (size No. 3) as made by Messrs. Tangyes, Limited, Birmingham, to whom I am indebted for the following particulars, upon which I will base an investigation of this governor. In the No. 3 governor, the weight W of each small ball is 2·9/16lb., and the weight W^1 of the load is 35·3/16lb. The weights of the upper and lower arms are 1lb. and ½lb. respectively, and the lift of the muff is 2in.

In the figure the governor is shown in its middle position, and the highest and lowest positions are indicated by dotted lines. In order that the system of weights may be in equilibrium in any position, the resultant of the forces acting on the weights must pass through the virtual centre of rotation of the system. This principle can be easily applied for calculating this or any other system of pendulum weight governors. Take, for example, the middle position shown and marked A B C. Continuing A B, until it meets a horizontal line drawn through C at O, then O represents the virtual centre of rotation of the system in the middle position, and, in order that the system may be in equilibrium, the resultant of the forces on one side of the governor must pass through this point. Combining the weights into one resultant F G (which, in the present instance, amounts to 21·6/16lb.), and drawing in the direction of the centrifugal force which must pass through the centre of the small balls, and the resultant which must pass through the virtual centre O, we can complete the parallelogram of forces F G H K, and find the value F K of the centrifugal force under which the system would be in equilibrium in this position. In the present example we find that this amounts to 34·13/16lb., and to develop this centrifugal force the speed must be 277 revolutions

$$(N = \sqrt{\frac{2{,}941C}{RW}}$$ where R = radius in feet, W = weight of ball

C = centrifugal force). We can thus determine the speed at which the system will be in equilibrium in any position, and we find that in this example the lowest and highest positions correspond to speeds of 264 and 281 revolutions per minute, showing a variation in speed of about 10 per cent., with a rise in the muff of nearly two inches. If the rise in the muff were made 1in. only, then the total variation of speed would be only 5 per cent. The sensitiveness is greatest in the lower portion of the lift, and becomes less as the muff rises. For many purposes the Porter governor can be made sufficiently sensitive, and it possesses the advantage of being extremely simple. The sensitiveness can also be further increased by increasing the length of the arms so as to place the point of suspension of each weight on the opposite side of the spindle.

The parabolic governor of Messrs. Galloways Limited is an interesting and ingenious modification of the loaded Watt governor. In this governor the place of the balls is taken by two cylindrical rollers suspended each by two arms, and the weight rests directly upon these rollers, the inside part of the weight in contact with the rollers being hollowed out to the form of a parabola. The weight is guided on the spindle and the muff forms a part of the weight. By the action of the component of the weight on the balls, in combination with the centrifugal force, and the tension in the arms, together with the weight of the balls, a governor is produced which can be made absolutely isochronous. The construction is also extremely compact, but —in common with all governors relying for their action on curved surfaces—it has the objection that its operation is modified by any wear on the parabolic guiding surface.

(To be continued.)

ROLLING MILL ENGINES.

ON page 396 we give an illustration of a pair of coupled rolling mill engines which Messrs. Duncan Stewart & Co., engineers, Glasgow, have erected at the Parkhead Rolling Mills, Glasgow, of Messrs. W. Beardmore & Co. The diameter of each cylinder is 42in., and the stroke 5ft. The piston rods are of steel, and are 6¼in. diameter at the front and 4½in. diameter at the back ends, where they are carried by guides. The connecting rods are of steel, and are 12ft. 6in. between centres in length, with a straight taper from 7½in. diameter at the crosshead end to 8¼in. diameter at the crank pin end. The steel crosshead pins are 8¼in. diameter and 9½in. long, and the steel crank pins are 9in. diameter and 10in. long. The cranks are of cast steel and balanced in an efficient manner. The crank shaft is of steel, and has journals 16in. diameter by 24in. long. The body of the shaft is 18in. in diameter, but is increased to 19in. diameter at the middle, where it receives a helical steel pinion 3ft. 7in. diameter, having eighteen teeth, 24in. broad and 7½in. pitch. The pinion gears with a spur wheel 8ft. 11½in. diameter, having forty-five teeth. The centre of the spur wheel is of cast iron, and is fixed to a steel rim by means of hardwood wedges. The large wheel is carried upon a steel shaft having journals 17in. diameter and 24in. long. The body of this shaft is 19in. diameter, but increased to 20in at the middle, where it receives the spur wheel.

* Paper read before the Manchester Association of Engineers on the 11th inst., by Mr. C. F. Budenberg, M.Sc.

Digitized by Google

The engines are fitted with piston valves, which work in separate valve casings bolted to the side of the cylinders. The steel valve spindles are 3in. in diameter. The eccentric rods are flat, bolted to cast-iron eccentric straps. The eccentrics are of cast iron, and have ample bearing surfaces. The link motion is operated by means of a reversing engine, which is simple but efficient, and has been specially designed for the purpose by the makers. The sole-plate for each engine is cast in one piece, and is of a very strong design. These engines have been working for some time and are giving every satisfaction.

INTRODUCTION OF THE ZONE RAILWAY SYSTEM INTO IRELAND.

In our issue of 17th October last we gave a short account of the new system of charging railway fares which has been introduced in Austria-Hungary—namely, the zone system, by which travellers are charged a uniform fare within certain zones of equal mileage breadth. We directed the attention of the public and of the railway authorities to the system, so that they might consider whether it would not be possible to introduce it, or a modification of it, into this country. In some local circular lines which are about to be constructed in Glasgow, we understand that it is proposed to charge a uniform fare for all distances, and this, in a sense, may be considered a beginning, but as yet none of the large railway companies have shown any disposition to adopt the system. The first practical attempt in the United Kingdom to adopt the zone system has been made by the Cork, Blackrock, and Passage Railway Company. The railway runs from Cork to Passage, a distance of about nine miles, and thence by steamboat to Aghada and Crosshaven, altogether about twenty miles, and calling at all the seaside resorts round Cork Harbour. Between Cork and Passage the fare will be 3d. third class, 5d. first class. Between Passage, Queenstown, and other stations in the harbour similar rates will be charged, and no reduction will be made on return tickets. The reduction on the fares by these arrangements has been very great, in the case of the long journey being as much as 50 per cent., and it is admitted by those responsible for them that the traffic must be doubled to make the experiment profitable. It is, no doubt, a bold thing to do, and we hope that the results will justify what has been done, but we must confess we would have liked to have seen the system introduced under more favourable conditions. We trust that some of our large railway companies may be induced to make a beginning on a part of one of their main lines, which would enable them to form an opinion as to the advisability of extending the arrangements throughout their system.

SHIPBUILDING NOTES.

On the 11th inst. Messrs. John Readhead & Sons, South Shields, launched from their building yard the steel screw-steamer "Bjorgvin," of the following dimensions:—Length, over all, 312ft.; breadth, 41¼ft.; depth, moulded, 24ft. 4in. The vessel will have the highest class at Lloyd's, under special survey, and Norwegian Veritas. She will be fitted with all the latest improvements for general cargo trades, and will carry about 4,400 tons dead weight. The engines, which have also been constructed by Messrs. Readhead & Sons, are of the triple-expansion type, having cylinders 23in., 37½in., and 61½in. in diameter, by 39in. stroke. The steamer has been built to the order of Messrs. Bergh & Helland, of Bergen.

On the 14th inst. the second of the three steam hopper barges for the Corporation of Preston, recently launched from the yard of Messrs. Wm. Simons & Co., of Renfrew, was tried on the Clyde, with satisfactory results. The measured mile was run at Gareloch, where the vessel attained a speed of nearly 10 miles, which was considerably in excess of that contracted for.

On the 15th inst. the "Sinclair," of Hartlepool, took her trial trip. She has been built by Messrs. Short Brothers, Pallion, and engined by Messrs. Wm. Allan & Co., of the Scotia Engine Works, the whole of the work being done under the superintendence of Mr. G. N. Arnison, Jun. The vessel is 180ft. long, and 29ft. broad, and her hold is 12ft. deep. On the run the engines developed a speed of 9 knots per hour. The vessel is fitted with Mason's patent pivoted side-lights in the saloon and also in the engine-room.

On the 20th inst. a small steamer was launched from the yard of the Naval Construction and Armaments Company, Limited, Barrow-in-Furness, for Messrs. Elder, Dempster, & Co., of Liverpool. Her dimensions are:—Length, 200ft.; breadth, 36ft.; and depth, moulded, 12ft. 9in. She was named the "Kevarra," and is intended for cargo-carrying purposes. She will be fitted with twin-screw triple-expansion engines, and is being built to class 90A at Lloyd's.

Notices of Meetings.

THIS WEEK.

Institution of Civil Engineers.—Friday, April 24th, at 7.30 p.m. Students' meeting. Papers to be read: "A New Type of Water Motor," by Mr. A. Sealy-Allin; "Hydraulic Power as Applied to Pressing Machinery," by Mr. H. Evington.

Balloon Society.—Friday, April 24th, at 8 p.m. Paper to be read: "The Indian Opium Question," by Mr. A. Rogers.

Royal Institution.—Saturday, April 25th, at 3 p.m. Lecture III., on "The Dynamo," by Professor S. P. Thompson.

North East Coast Institution of Engineers and Shipbuilders.—Saturday, April 25th, at 6 p.m. Resumed discussion on Mr. W. Hök's second paper on "The Unsinkability of Cargo-Carrying Vessels." Paper to be read: "Water Gauge Fittings for Steam Boilers," by Mr. H. Gray.

NEXT WEEK.

Institution of Civil Engineers.—Tuesday, April 28th, at 8 p.m. Ordinary meeting. Paper to be further discussed: "The Cost of the Generation and Distribution of Electrical Energy," by Mr. R. E. B. Crompton, M.Inst.C.E.

Society of Arts.—Wednesday, April 29th, at 8 p.m. Paper to be read: "The Use of Petroleum in Prime Motors," by Professor W. Robinson. Thursday, April 30th, at 4.30 p.m. Paper to be read: "The Perrier Irrigation Project, Madras Presidency," by Colonel J. O. Hasted, R.E.

Royal Institution.—Thursday, April 30th, at 3 p.m. Lecture on "Recent Spectroscopic Investigations," by Professor Dewar, F.R.S.

PRICES CURRENT, 22nd April, 1891.

Quotations at per ton, unless otherwise specified.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper: A weaker tone has been noticeable during the past few days, and prices are a shade lower. The total visible supply of copper increased about 1,170 tons during the first fortnight in April, and this has had an unfavourable influence on the market, values of Chili bars having declined. Prices to-day, however, are steadier, quotations being £51 to £51 7s. 6d. cash. Manufactured £64 to £65, according to order.

Tin: Foreign has declined about £1 per ton during the past week, but prices are again slightly firmer.

Lead: Weaker, with small demand.

Spelter: Slightly easier

PIG IRON—BRAND "CARRON."

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Chemicals: There is at present little fresh inquiry for carbolic acid crystals, but there is more disposition to buy the crude article. Benzoles are neglected, and prices are again lower. Sulphate of ammonia is steadier, but there is no large amount of business passing. Sulphate of copper is freely offered, values, however, not varying much. Green copperas is easing. Sulphur continues in demand and scarce.

We have received from Messrs. Rose, Downs, & Thompson, Old Foundry, Hull, a copy of the eighth edition of their Catalogue of Oil Mill Machinery, &c. In the catalogue, descriptions and illustrations of all the various plant required in an oil mill are found, such as hydraulic presses, hydraulic pumps, accumulators, edge stones, oil filters, &c.

Messrs. Thos. Fleming, Son, & Co., of Halifax, have sent us a copy of their new Price List of Leather Belting, Belt Fasteners, &c. In addition to prices, much useful information is contained in the price list, as, for example, "Hints to Users of Leather Belting," "Table of Horse-Power of Belts," and "Useful Rules, Information, and Mechanical Data."

HOME INDUSTRIES.

LONDON, 23rd April, 1891.

The Money Market.—A more settled feeling has pervaded the money market since the Bank Rate was raised on the 16th inst., and, though outside rates have been well maintained, the improvement in the position generally has reconciled all interests to the higher values of money. London has been relieved from the drain of gold for the Continent, which, by the action of the large houses, has been diverted so as to fall on centres better provided with the metal or less sensitive to demands on their stocks of it. Inactivity has been the prevailing feature of the stock markets. The American department has shown some activity, a strong "bull" campaign in Wall Street having galvanised London into sympathetic movement. The advance in Americans has been fairly well kept up, though there have been sets-back and reactions due to speculators for the rise taking their profits. But each of these has simply encouraged fresh buying, and the general tone has been brisk and firm. This activity has failed to influence other departments, even Canadian railways, which usually follow in the wake of Americans, failing to do so this time. Home railways have been quite inactive. Foreign bonds have presented few points of interest, the fluctuating movements of Portuguese and Argentines excepted. Miscellaneous securities remain lifeless, but the mining market has become much brisker, though speculation there is restricted to one or two mines that have suddenly advanced into favour.

The Iron and Steel Institute.—The annual meeting of this Institute will be held at the rooms of the Institution of Civil Engineers, on the 6th, 7th, and 8th of next month. The proceedings will commence each day at 10 a.m., and will close not later than 2 p.m. The following is the list of papers, but the Council have not yet determined the order in which they shall be read:—"On the Ironmaking Resources of the Southern States," by Professor J. R. Procter; "On the Coke Industry of the United States," by Mr. J. D. Weeks; "On the Manufacture of War Material in the United States," by Mr. W. H. Jaques; "On Tests for Steel used in the Manufacture of Artillery," by Mr. Wm. Anderson; "On Certain Pyrometric Measurements and the Method of Recording Them," by Professor Roberts-Austen, F.R.S.; "On the Changes in Iron Produced by Thermal Treatment" (supplementary paper), by Dr. E. J. Ball; "On a Graphic Method of Calculating the Composition of Furnace Charges," by Mr. H. C. Jenkins; "On the Calorific Efficiency of the Puddling Furnace," by Major L. Cubillo; "On Economical Puddling and Puddling Cinder," by Mr. Thos. Turner; and "On the Micro-Structure of Steel," by M. Osmond.

Institute of Marine Engineers.—At a meeting of the Institute of Marine Engineers, held on the 14th inst., Mr. F. W. Wymer being in the chair, a paper on "Mean Pressure of the Compound Engine" was read by Mr. D. McMillan. The subject matter of the paper treated of the relative position of cranks, the different proportions of receivers, the ratios of expansion, economy at different rates of expansion, and methods of proportioning cylinders. The author, from long experience of the working of marine engines at sea, and taking the evidence of indicator diagrams, found that the practical results were from 20 to 38 per cent. below the calculations from the accepted theoretical powers. The author gave details of various types of engines working under different circumstances. Mr. Brown said he tried to get the same power from each cylinder as nearly as possible, except in the cylinder driving the pumps, which should have a larger share. Mr. McFarlane Gray illustrated by a diagram a simple method of arriving at the size of cylinders for any class of engine, whether compound, triple, or quadruple.

Royal Meteorological Society.—At a meeting of this Society, held on the 15th inst., Mr. A. Brewin, Vice-President, being in the chair, a paper on "Some Remarkable Features in the Winter of 1890-91" was read by Mr. F. J. Brodie. The author stated that the barometric pressure for the whole winter was about ⅛in. above the average; and that when the wind was not absolutely calm there was an undue prevalence of breezes from some cold quarter. The percentage of winds from the southward did not amount to one-half of the average, and the number of foggy days in London was no less than twice the average. The winter of 1890-91 might well be termed the "anticyclonic" winter. In a paper on "The Rainfall of February, 1891," Mr. H. S. Wallis said that last February was one of the driest months upon record; the mean rainfall over England, excluding the Lake District, being only 0·066in., or about one-fortieth of the average. Mr. H. F. Blandford read a paper on "The Variations of the Rainfall at Cherra Poonjee, in the Khasi Hills, Assam." The author stated that the mean annual rainfall at Cherra Poonjee was frequently given as about 600in., but it was probably only a little over 500in.

The "Centrifugal" Gold Process.—Messrs. T. B. Jordan & Son, of 15, George Street, London, E.C., have sent us some particulars of the above, showing the necessary machinery required for a complete plant for the "Centrifugal" gold process. The process requires two machines, the fine reducer and the amalgamator, which we described in *Industries*, Vol. XI., page 128. A plant of this kind has been for some time at work in South America with very good results upon ores containing arsenic, and a very fine float gold, exceedingly difficult to treat.

MANCHESTER, 23rd April, 1891.

The Fifty-three Hours Movement.—The movement for the reduction of the working hours is developing. Although officially the employers' association declines to accede to the request of the trade union, the point is being conceded by a number of the large firms. The firm of Messrs. Samuel Brooks, who employ more than 1,000 workpeople, have announced their intention to agree to the reduction, and their action is likely to influence several others. The joint committee of the various trade unions concerned has adopted a resolution threatening to withdraw the men from their employment in shops where the concession is not made by the 25th inst., but it is generally agreed that this course will not be necessary in many cases.

Business Announcement.—The business of the Union Engineering Company, which has hitherto been carried on as a private partnership, has been transferred to a limited liability company with the same title. The company has been engaged in constructing large fans for mine ventilation, and has recently taken up the manufacture of a special condenser.

An American Lathe.—We have recently seen a lathe made by the Brown & Sharpe Manufacturing Company, at the works of Messrs. Hutchinson, Hollingworth, & Co. The saddle is mounted upon a bed, one side of which has an inverted V, the other side being flat. The saddle has also a vertical working face at the back, which steadies it considerably. An ingenious and simple release motion is fitted for use in sliding and screw cutting, and the workmanship of the lathe is excellent. Although hardly fitted for rough work in a shop, it is admirably designed for accurate work, such as tool making.

The Ship Canal.—The first lock connected with the Ship Canal, that at Weston Marsh, which is to take the traffic between the River Weaver and the Ship Canal, was opened on the 16th inst. The lock, which is 315ft. long, 42ft. 6in. broad, and 16ft. deep, has three pairs of gates, the intermediate ones dividing the basin. The gates are worked by hydraulic power, obtained by using the water of the Weaver Canal, and are put into gear by friction cones. The machinery has been constructed by Messrs. Cleghorn & Wilson, Weaver Foundry, Northwich. Boats can pass through the locks in from three to four minutes. The gates, which are made of the finest greenheart, have been tested by the Weaver Trustees, and are perfectly tight.

The Linen and Jute Trades.—Forty-inch 10½oz. Hessians have fluctuated lately, but purchases during the week have been satisfactory. There is a steady demand for linens, and hopes are entertained that recent disappointments will be allayed between now and Whitsuntide. The demand for fancy goods has been one of the principal features of the week. German manufacturers have secured a large portion of the trade, and their connection increases from year to year. Irish and Scotch firms seem indisposed to compete for the trade, and confine their attention to ordinary Dunfermline and Belfast ranges. Some persons think that this is a source of serious loss, while others think that the branches of trade in which our manufacturers are engaged are those of chief importance. The shipping trade is rather dull. South American trade does not improve, and the prospect is unsatisfactory.

An Improved Paper.—Messrs. Crompton, of Bury, are introducing a new paper, which is intended to take the place of the ordinary makes of paper used for lamp shades and similar purposes. By a special process the paper is toughened, so as to be nearly untearable, and as it can be easily manipulated there appears to be a wide field for its application. The paper is called by the makers wrinkled or crêpe tissue paper.

GLASGOW, 23rd April, 1891.

The Recent Railway Strike.—The Glasgow and South-Western Railway has made further important concessions to the men employed on the system. The outcome of these concessions is that the goods and mineral guards have now practically a ten hours' day. Shunters and yardsmen in busy yards have had their hours reduced to eight. Signalmen also, in busy signal boxes, have been put upon eight-hour shifts. Hours have also been shortened in the locomotive departments. One of the most important of these re-arrangements is the abolition of the booking system. On the North British Railway matters are by no means going so smoothly. On the Fifeshire lines agitation against reduced wages is still going on, and complaints are being made that the terms of the arrangement between the directors of the company and the deputations from the men are not being adhered to.

Minerals.—The shipments of Scotch pig iron are still decreasing. The total decrease for the year is 67,547 tons, the decrease for last week having been over 6,000 tons. Coal shipments, on the other hand, have exhibited a remarkably rapid expansion. Should the rate of increase be maintained next week, the decrease on the four months of the year will have been almost altogether extinguished. The increase on last week was 24,604 tons, diminishing the decrease this year to 28,498 tons. This expansion, so far as the coal trade is concerned, recoups to some extent the losses due to the strike, although a large part of the increase is not entirely due to the deferred traffic of the strike, and it cannot therefore be said to be a complete set-off against the loss due to that cause. It is to be noted, however, that the whole of this increase occurs in the Scottish ports other than Glasgow, chiefly, in fact, in Ayr and in the ports of the East Coast. The Glasgow shipments show a decrease for the week of 3,000 tons.

New Ammonia Plant.—The Coltness Iron Company, Limited, have just erected a new set of plant for the recovery of ammonia. The plant is capable of treating the produce of six furnaces. The quantity of gas dealt with is, at 400° Fahr., about 100 million cubic feet, or in a cold dry state 60 million cubic feet daily. The chief novelty in the plant is the introduction of a dust chamber, a dome-shaped vessel of 40ft. in diameter by 65ft. high. The dust chamber, devised by Mr. Young, of Peebles, enables the dust to be separated from the gas, so that the latter may pass to the subsequent processes free from dust particles. The contractors for the plant were the Barrowfield Iron Company, Limited, the buildings having been erected by the Coltness Iron Company themselves.

The East End Exhibition.—The Glasgow East End Exhibition, which was opened on the 23rd December last, mainly with a view to provide an opportunity for artisans to exhibit their handicraft works, was closed on the 21st inst. by the Earl of Aberdeen. The Exhibition has been a decided financial success. During the seventeen weeks of its existence it has been visited by 746,107 persons, and the result is a surplus of about £3,500. Any surplus that may be realised from the Exhibition is to be devoted to a fund for the erection of a people's palace in the East End of the city.

Failure of an Engineering Firm.—It has been announced by Messrs. Arrol Brothers, of Germiston Iron Works, that, on account of the Provincial Government of Buenos Ayres having failed to meet its engagements to them in respect of a large contract which they had undertaken, they are unable to meet their own engagements. This result of the troubles in the Argentine is universally regretted in commercial circles, the firm, a comparatively young one, being well known and highly respected. The liabilities are estimated at about £50,000.

Shipbuilding.—H.M.S. "Indefatigable," second-class cruiser, is being rapidly pushed forward towards completion. The vessel is now moored alongside the yard of the London and Glasgow Engineering and Shipbuilding Company, Govan.

(From our own Correspondents.)

LIVERPOOL, 22nd April, 1891.

Liverpool Engineering Society.—At a meeting of this Society held to-day, under the presidency of Mr. J. T. Wood, a paper was read by Mr. George Farren, on "Denudations at Aber-Menai, Anglesea." The author said that on account of the natural bank at the Carnarvon entrance to the Menai Straits being gradually denuded, the former deep entrance is being changed into a wide and shallow one, so as to interfere with the navigation of the ships wishing to enter the port of Carnarvon or to pass through the Straits. Mr. Farren described the means adopted for arresting the danger.

The Canadian Mails.—The contract between the Canadian Government and the Allen Line for carrying the mails having terminated, and the Canadian Government having declined an offer by the company to continue carrying the mails at the same subsidy as in previous years, all mails for Canada will now have to pass through New York. This alters the date of posting and probably the amount of postage, and the Allen Liners will probably cease calling at Londonderry.

The Atlantic Cattle Trade.—The report of the Government Commission of Inquiry into the Carriage of Live Cattle by Sea, which is to be presented to Parliament in July, will be an interesting document. The members of the Commission yesterday inspected the new steamer "Nomadic," built for the White Star Company specially for the Atlantic cattle trade, and in accordance with the suggestions of the Commission.—In reply to the book published by Mr. Samuel Plimsoll, a digest of the evidence and statistics has been prepared by the Liverpool Steamship Owners' Association.

LEEDS, 22nd April, 1891.

The Iron and Steel Trades.—The quietness in the iron trade of this district will probably become more accentuated before any great improvement takes place. Slackness in placing orders is apparent in all branches of the trade, though possibly this feeling might be overcome by a lowering of prices both for pig and finished iron. Producers, however, can hardly be expected to do much in the direction of lessened quotations, for at the present time prices are practically unremunerative, owing to the heavy cost of fuel and the rate of wages paid. Work is now less brisk than it was a fortnight ago. Orders for railway material have fallen off considerably during the year. At the various foundries work is reported to be plentiful, some of the firms executing large castings. The steel trade is more brisk than the finished iron industry, and the Leeds Steel Works are tolerably busy. There is a fair amount of employment in the engineering shops. Builders of locomotives, especially the smaller descriptions, remain busy, and machine and tool makers have orders for some little time.

The Hull and District Institution of Engineers and Naval Architects.—At a meeting of this Institution, held on the 14th inst., under the presidency of Mr. C. F. Ames, a paper on "Forced Draught on Steamships" was read by Mr. A. E. Seaton. "Forced draught" was defined by the author as "any means whereby the products of

Digitized by Google

combustion are caused to flow from the chimney at a greater velocity than that due to a column of air of different specific gravity from that of the surrounding air, or any means whereby the inflow of air to the furnace is greater than that due to the draw of the chimney from above cause." Mr. Seaton dwelt upon the influence which the relative dimensions of the funnel, furnace, firebars, and also the extent and character of the heating surface, had upon the results obtained, and he described the various systems which have been introduced for the purpose of obtaining increased combustion.

SHEFFIELD, 22nd April, 1891.

The Iron and Steel Trades.—There is a general decrease in the demand for iron and steel structures. Many of the large orders have been completed, and there are not many new orders. For steel castings orders are scarce. The high rate of wages now paid to the moulders and the heavy cost of fuel have made work almost unremunerative. Many engineers are going back to cast iron, or depending upon riveted plates, built up with angle, tee, and other sections of rolled steel, which can now be obtained at a reasonable price. It is much to be regretted that Sheffield cannot compete with German firms for the light steel castings used in agricultural implements.

Coal.—The coal trade is brisk, and local collieries are working full time. The demand for steam and household coal does not decrease, and the amount sent by rail to London is fully up to the average.

The Royal Naval Exhibition.—Local firms are to be well represented at the Chelsea Exhibition. Messrs. Vickers, Messrs. Cammell, Messrs. Firth, and Messrs. Brown will each show the progress made in recent years by metallurgists and naval engineers.

Cutlery.—The cutlery trades are not well employed, and there are some serious disputes pending between manufacturers and their workmen.

NORTH STAFFORDSHIRE, 22nd April, 1891.

The Iron Trade.—The improved tone of the Scotch warrant market, though probably only temporary, has imparted a firmer feeling to the iron trade generally, and buyers have no intentions of being found without stocks or forward contracts, in case of a reaction. It is generally recognised that prices at present are unremunerative. Unless the cost of production is reduced trade will be seriously affected. Contracts for finished material are now being entered at £3 per ton below the rates ruling for similar qualities in January of last year.

The North Staffordshire Chamber of Commerce.—At the meeting of the Chamber last week the subject of canal communication with Liverpool was again under consideration, and more particularly the scheme for widening the existing waterway by the North Staffordshire Railway Company—its owners. A deputation was appointed to wait upon the general manager of the company, to urge that the work should be thoroughly and efficiently carried out.

BIRMINGHAM, 22nd April, 1891.

The Iron Trade.—Since the quarterly meeting of the iron trade on the 8th inst. there has been rather more disposition to buy, and prices have been firmer. Slit rod makers have met and decided not to reduce "Crown" rods from the price of £7 10s. per ton. Strip makers reduced their price to £6 5s. on "quarter day." The marked bar firms have maintained their figure of £8 per ton, and there is a large demand for "Lion" bars for home and export. Common bars are still quoted at £6, cable bars £6 5s. Sheets are very low in price, at £7 per ton, and in some special cases orders are being taken at less prices. Galvanised sheets (24 G) are £11 15s. per ton.

Steel.—There is a good demand in the district for steel. Engineers are fairly busy, as also are hollowware makers and manufacturers of cycle fittings, who use little else than steel now. Steel boiler plates are sold at £8 per ton in the district. Bars are at £7, with £7 10s. for acid Siemens qualities. Sheets are about £7 15s. per ton for singles. There is a large demand for steel tube and hame strip at about £7 10s. per ton. One firm of tube makers are using electricity for welding their tubes.

Chains and Cables.—There is a better demand for chains and cables. The operatives have passed resolutions that they will work only four days per week, so as to restrict the output. The female workers generally object to the proposed interference of Parliament with their hours of labour.

Birmingham Water Suppply.—The scheme for a new water supply of 60,000,000 gallons per day, which was fully described in our last issue, was approved yesterday by the City Council by a unanimous vote.

LEICESTER, 22nd April, 1891.

Wool Spinning and Yarn Trades.—The local wool market remains very firm at the late small advance in price. The tendency appears to be upwards, especially in the leading descriptions. This aspect of the market makes consumers extremely cautious, and as they have liberally supplied their wants during the past fortnight, there is now not quite so much business doing. Spinners are on the whole well employed, but they complain much of the unremunerative prices at which business has to be done. There is a steady demand for lambswool and fancy yarns, and there is a small attempt to obtain better prices, but a movement in this direction soon checks business.

Hosiery Trade.—There is an improvement in this industry. The season orders are now being placed, and are for satisfactory amounts. But this kind of order is not greatly appreciated in view of the results of the past year or two, when good orders were placed and in numerous instances not exhausted. This result makes it hard for the manufacturers. The continued cold weather greatly checks the demand for light goods. There is an improvement in the shipping department which is satisfactory.

BARROW-IN-FURNESS, 22nd April, 1891.

Hematite.—There is no improvement in the demand for hematite pig iron. Hematite warrants are quoted today at 48s. 7d. per ton net cash, while mixed numbers of Bessemer iron are quoted at 50s. net f.o.b. The business is chiefly confined to hematite warrants, which are being reduced to a considerable extent, the decrease this week representing 5,388 tons, leaving the total of stocks in hand at 169,677 tons. Forty furnaces are in blast and thirty-six are standing idle.

Shipbuilding at Barrow.—Trade is at present very good here. Mr. Alexander Adamson, formerly shipyard manager of the Naval Construction and Armaments Company, Limited, has been appointed by the board of directors to the position of general manager of the company in place of the late managing director, Mr. A. D. Bryce-Douglas. Mr. Adamson has had excellent experience in Clyde and Tyne yards, and has been associated throughout with Mr. Bryce-Douglas at the Barrow works. Mr. Blechynden continues manager of the engineering department.

MIDDLESBROUGH, 22nd April, 1891.

Pig Iron.—The iron market is more favourable in tone this week, and prices of pig iron are better, though there is little increase in the amount of business. Consumers do not believe that the advance in prices arises from any genuine improvement in trade, but is brought about by a scarcity of warrants, the holders of which do not feel inclined to sell at present. The market, however, is being influenced by the diminished production of pig iron, the steady decrease in stocks in the public warrant stores, and the improving shipments. A few orders have recently been received from the Continent. The quotations of merchants for prompt f.o.b. deliveries of No. 3 G.M.B. is about 39s. per ton, a figure which some of the makers will take, though they complain that the prices are unremunerative. Makers ask from 39s. to 40s., the most frequent figure being 39s. 6d. Middlesbrough warrants are higher than merchants' iron, buyers offering 39s. 3d. cash, and sellers asking 39s. 6d. The stock in Connal's store on the 20th inst. was 117,736 tons, a decrease of 4,958 tons this month Grey forge has advanced in sympathy with No. 3, and producers ask 38s. per ton, buyers being ready to give 37s. 9d., which is 9d. more than last week's rate. The Scotch consumers are taking more of this quality than might be expected, considering that there are now fifty-two furnaces at work in that district, forty-six having been relighted since the strike ended last month. Local consumption is poor, however, as so many of the finished ironworks are short of orders. Local hematite pig is quoted at 51s. per ton for mixed numbers.

Manufactured Iron and Steel.—In the finished iron and steel trades there are no signs of improvement. Producers complain of the scarcity of orders, and several establishments are only moderately employed. Common iron bars are £5 12s. 6d.; iron ship plates, £5 12s. 6d; iron ship angles, £5 10s.; steel angles, £5 17s. 6d.; iron ship plates, £5 12s. 6d.; steel ship plates, £6 2s. 6d.—all less the usual 2½ per cent. for cash, and f.o.t. at producers' works.

Coke.—Good blast furnace coke can be purchased at from 13s. 3d. to 13s. 6d. per ton delivered here.

Shipments.—Shipments of pig iron are decidedly improving, and amounted to 22,167 tons last week, as against 14,292 tons the previous week. The total shipments for the month up to the 20th inst. were 49,957 tons, as against 42,327 tons up to the same date of the previous month. Of this quantity, 26,045 tons went to Scotland, 4,683 tons to England and Wales, and 19,229 tons to foreign parts.

Work and Wages.—The Seaton Carew Iron Company are blowing out one furnace, which makes the twelfth stopped in the district since November last. A meeting of the Cleveland mine owners and the miners' representatives was held yesterday to consider the proposed reduction of 10 per cent. After a discussion lasting over five hours the following terms were agreed upon:—"The Cleveland miners being unable to admit the justification, in the present state of trade, for the reduction of 10 per cent. claimed by the mine owners, but having offered to accept a reduction of 5 per cent., and the mine owners being unable to accept this amount otherwise than as a part of the larger reduction, which they still maintain to be due, but being desirous of avoiding the strain on the relationship of the parties which might arise by the giving of notices, it was mutually agreed that a 5 per cent. reduction shall take place from the 13th inst., and to extend to the 30th of May, and from that period negotiations shall be renewed, and a meeting shall be held on the 30th or 31st of May for that purpose."

NEWCASTLE, 22nd April, 1891.

The Coal Trade.—In the local coal trade demand is still active, and recent prices for all qualities are maintained. The shipments of coal and coke from Tyne Dock during the week ending the 18th inst. amounted to 112,631 tons, being a decrease as compared with the shipments for the corresponding week last year of 8,495 tons.

Engineering.—Messrs. R. Stephenson & Co. have obtained a good order for locomotive engines, and for some time to come this department of their works will be kept busy. Messrs. H. Charlton & Co., of Gateshead, who are the successors to Messrs. Hawks, Crawshay, & Sons, as manufacturers of the improved Martin's anchors, have just despatched from their works three powerful 6-ton anchors ordered for the Russian warship "Navarino." The firm have orders for a large number of anchors varying from four to six tons in weight.

New Flour Mills.—On the 18th inst., at Dunston-on-Tyne, the new flour mills of the Wholesale Co-operative Society, which have been erected at a cost of nearly £100,000, were formally opened. The mills have a river frontage of 464ft. The two main engines, which have been supplied by Messrs. T. Robinson & Sons, Rochdale, are of the improved tandem type, and can develop 350 i.h.p. The roller milling plant has been supplied by the same firm. There are two mills, and each set of plant will produce twenty sacks (280lb. each) of finished flour per hour, and the united production of the mills is estimated at 5,600 sacks per week. The flour mills have been lighted throughout by Messrs. Ernest Scott & Mountain, electrical and general engineers, Close Works, Newcastle-on-Tyne. This installation is very complete in its details, and consists of about 600 16 c.p. incandescent lamps. The generating plant consists of two vertical 60 h.p. engines, and one of 15 h.p. The two larger engines drive two of Messrs. Ernest Scott & Mountain's "Tyne" 400 lamp dynamos. The jetty and mill yard is lighted with ten 2,000 c.p. "Tyne" arc lamps, the current for these lamps being supplied by a compound dynamo driven by the small vertical engine. Four arc lamps on the jetty are carried on 25ft. poles and fitted with raising and lowering gear.

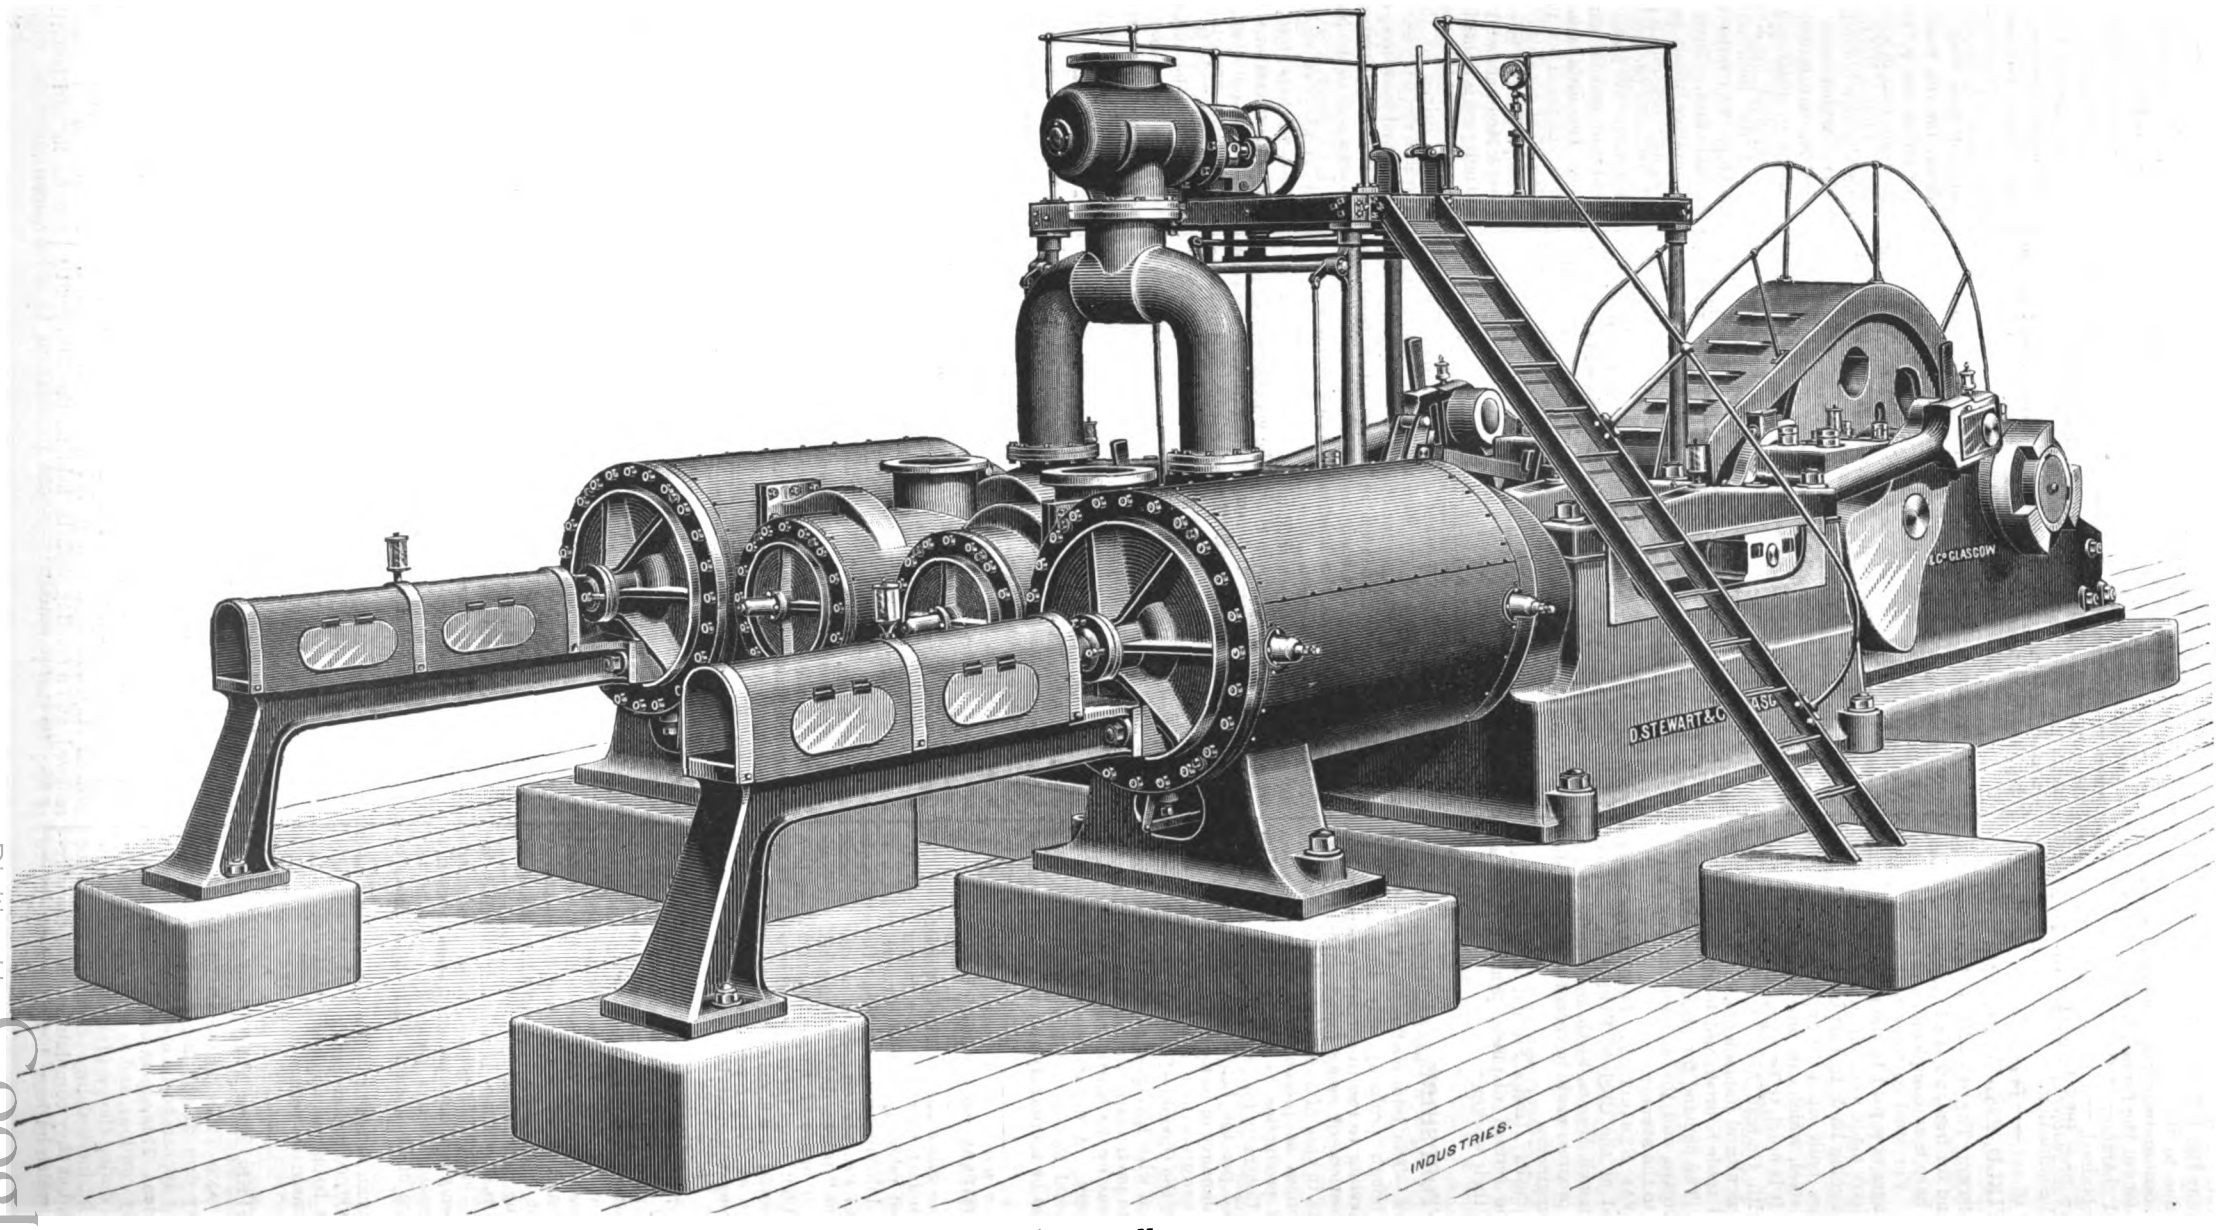
Electric Lighting.—Some fine electric lighting plant has been sent to the Naval Exhibition at Chelsea by Messrs. Clark, Chapman, & Co., of the Victoria Works. The firm will also exhibit at the same stand some powerful projectors, and one of their high speed turbo-electric generators.

Ship Repairing.—During the past few weeks the ship repairing establishments on the river have been very busy. Among other important contracts is the repairing of the s.s. "Energie," at Messrs. Edwards' dock, North Shields. The vessel, which belongs to German owners, is, we understand, the first ship that was specially constructed, in accordance with Swan's principle, for the carrying of oil in bulk, and she was launched from the Low Walker Yard of Messrs. Armstrong, Mitchell, & Co., about six years ago. The statement that the new steamer "Europe," built by the Palmer's Company, and which is 440ft. in length, had to be taken to the Wear to be docked, there being no graving dock on the Tyne large enough to receive her, is incorrect, as Messrs. Hawthorn, Leslie, & Co.'s dock is capable of accommodating even larger vessels.

DUNDEE, 22nd April, 1891.

Proposed Automatic Railway at the Harbour.—The Dundee Harbour Engineer, Mr. W. Cunningham, has constructed "a short section of a scheme for transporting jute by means of an automatic railway on a full-sized scale." The purpose of the railway is to provide a means for transporting bales of goods from the ship's side to sheds which are at some distance from the landing place. The automatic railway has been so arranged that two vessels may be discharged simultaneously. Mr. Cunningham estimates that from 15,000 to 18,000 bales of jute can thus be landed in ten hours. The trucks are run on an endless rope tramway, and catch the bales of goods as they are delivered from the hatch by means of a shoot formed of a series of rollers. At the point of discharge the bales are automatically tilted out of the trucks. Last week some trials of the automatic tramway were made, and gave very successful results.

Sewage Purification.—The first installation in Scotland of the "International" sewage purification process has been made at the Stirling District Lunatic Asylum, Larbert, under the supervision of Messrs. A. & W. Black, surveyors, Falkirk. The new process supersedes the system of land irrigation formerly in use, and the trials, extending over a period of about one month, have given very satisfactory results.



Jute and Flax Trades.—Both branches of the local industry continue active. Cable advices from Calcutta are to the effect that the crop is suffering from want of rain. There is little business done in the new crop, and quotations are unchanged. Jute yarns continue firm in tone, but buyers are not purchasing freely at the prices asked. Light-weight jute goods are in steady demand at recent rates. In the New York market light-weights are quoted at 4 13/16c. per yard, and burlaps 40in. 10½oz. at 5c. per yard. Flax is in limited demand, but consumers' stocks are said to be small, and the market is therefore strong. The market for yarns (especially the fine sorts) is also firm. Manufacturers of linens are fairly busy, and orders are coming in satisfactorily both from home and foreign markets.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to ensure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

Industries:

FRIDAY, 24TH APRIL, 1891.

THE FUTURE OF INDUSTRY AND LABOUR.

THERE is a prevailing impression that we are on the eve of a period of more or less pronounced dulness of trade, and that the future has little brightness in store for our staple industries. This impression has undoubtedly received a large amount of colour from the very marked decline in the amount of our exports of home produce and manufactures during that part of the present year which has already elapsed. There has been a contraction of demand and of manufacturing operations in many directions, and notably so in our staple industries of iron making, constructive engineering, and shipbuilding. The chemical industries, which Lord Beaconsfield looked to as the most reliable barometer of trade, have also been less buoyant, and they are not likely to be improved by the operation of syndicating all the principal works with a view to the limitation of output and the maintenance of prices. The one cheerful and agreeable oasis in the desert of our industrial outlook is the coal industry, which maintains its activity, in response to an unprecedentedly large demand from many sources. Unfortunately this activity lies at the root of the troubles of some of our staple manufacturing industries, which, but for the continued high price of fuel, would be in a much more satisfactory condition.

It is natural to look at first for causes that lie on the surface, when an attempt is being made either to learn the actual course of the trade of the country or its prospects. But many side influences have combined within the last year to induce the stagnation that has overtaken the commerce of the world—for the altered condition of business affairs is by no means limited to the United Kingdom. The Argentine crisis has been generally assigned as the main cause of the contraction of commercial operations and the lessened confidence in the future. Undoubtedly, that crisis has had much to do with the case. It gave a rude shock to English credit, and proved that much of the business that had been done in recent years was unsound. The recognition of this fact was the chief cause in producing the present financial and commercial situation. It was ascertained that we had nearly 150 millions of British capital locked up in Argentina, and exposed to imminent peril of absolute loss, and this knowledge led the financial world to inquire whether we were not similarly placed in relation to other countries, and, perhaps, even to doubt whether any country, new or old, was solvent and safe. While this spirit of unrest and distrust was rampant, further business based on the operations of credit and speculation was all but impossible. The affairs of Argentina were, however, after all, only an episode in the situation. The money invested there has not by any means been lost, although for a time it may be unproductive; but even if it had been irrecoverably lost, the loss of a hundred millions is hardly an event that would leave permanent traces on a nation that has an annual income of fifteen times that amount, and whose accumulated capital is computed at nearly 10,000 millions sterling. The future is not, therefore, likely to be obscured for any very long time by Argentine troubles; and, if the depression threatens to continue, we must look elsewhere for the cause.

There is no factor that gives more anxiety to the industrial world than the labour problem, which of late years has been forcing itself upon the attention of all classes with a persistence and an aggressiveness that is not to be ignored. It is not, however, a new thing with us; like the poor, it has been always with us. Germany, Belgium, and other Continental countries, where it had formerly been less obtrusive, are now passing through experiences in relation to labour questions that England had undergone many years ago. In Australasia, and in other colonies, labour questions have forced themselves upon public notice with as much energy as they ever did in the mother country. The United States are continually experiencing the same sort of difficulties, which appear likely to become chronic. It is doubtful whether England is not in a better condition with reference to this matter than any other prominent industrial country. It is true that we have not yet succeeded in crushing the head of industrial anarchy, nor have we found any effectual solvent of the problems that so beset the political economist. It may be, indeed, that we are only on the verge of a long, difficult, and costly process of readjustment of the relations of labour and capital, resulting from the necessary accommodation of the earnings of the former to the diminished profits of the latter. But in some of our principal industries, as, for example, the iron and coal trades, we have machinery already at work, which is capable, if continued in operation, of effecting that process by "the easy, artless, unencumbered plan" of a sliding scale, and in others there is usually a recognised relation of wages to prices that makes the process less difficult than it otherwise would be. In Germany, the United States, and other industrial countries, all this has more or less to be commenced *de novo*, and such standards remain to be established. One fact, that stands out with very conspicuous prominence in the midst of this universal restlessness of labour, is the tendency that has been recognised by political economists, both at home and abroad, towards an equalisation of the conditions of labour in different countries. Another fact, now almost equally well established, is the tendency that exists to secure for labour an increasing share of the joint product of industrial work. The facilities for inter-communication between the proletariat of different countries make them not only kin in their aims and objects, but in their ultimate achievements. Wages are necessarily higher or lower according as the cost of living is more or less in different countries, but in spite of the operation of Customs tariffs, State bounties, and other restraints on the natural laws of trade, there is a constant movement in the direction of the equalisation of the cost of living, and, consequently, also of the rate of wages paid for a day's labour. Much has, of course, to be done before this movement will attain its full growth. There is still a great gulf fixed between the coolie labour of the East and the navvy labour of our Australian colonies. But both alike come into the final determination of industrial supremacy, for the Australian colonies hope to establish an indigenous cotton industry, which, in New South Wales, at any rate, as a Free Trade colony, would have to compete in its own markets with the cotton products of India.

Digitized by Google

These, however, are the extremes of the case. What is of more immediate concern to us, at the present time, is the fact that Continental labour is undoubtedly becoming more expensive, by reason of the reduction of the hours of labour, and of the agitation which has forced up the rates of wages. Should the time come when the rates of wages are as high, and the hours of labour as short, as in England, the latter country will certainly not be in a worse position in reference to international competition than it occupies at the present time. Many whose opinions are entitled to much respect appear to think that it is to the United States that we must look in the future for successful competition in neutral markets. The United States, however, is a land of surprises. If the present tariff laws were repealed it is probable that wages would fall very rapidly, in response to a fall in prices. But that is not a contingency upon which any wise business man would at present found his calculations. It appears probable that the tariff of last year will soon be greatly modified, but it is a far cry from extensive modification to absolute Free Trade. Meanwhile, England has more to expect from the former event than from the latter. Under a system of comparatively low duties she could probably do a good business with the United States, although it would be uncertain and spasmodic, but under the latter system the American factories and workshops would speedily be reorganising their arrangements in view of a life and death struggle for the supply of their own markets.

The newly appointed Labour Commission will be called upon shortly to deal with some, at least, of the problems of which we have just given an outline. It would be too much to hope that the Commissioners can make any suggestions that would alter the course of events, but if they can accurately indicate their direction they will be likely to do some service. While labour troubles are impending on all hands, and while the manufacturer is almost afraid to accept a contract lest he should be thwarted by the action of his workmen, and involved in losses and lawsuits, it is naturally impossible that the machinery of industry or of commerce can work so smoothly as it would do if labour difficulties were more easily settled. It is not too much to say that at the present time employers, and especially large manufacturers, look with apprehension to their future relations with their workmen. They would give much to have a clear outlook ahead, but this at present appears all but impossible. It is more particularly difficult at a time like the present, when prices are falling on every hand, and when profits over a large area of business operations have become attenuated almost to the vanishing point.

AUSTRALIA AND TRADE.

There have recently appeared three rather important contributions to literature on colonial subjects. These are an essay on "State Socialism in the Antipodes," in the volume of papers called "A Plea for Liberty;" an article on "The Seamy side of Australia," in the April number of the *Nineteenth Century*; and one on "The Eight Hours Day in Victoria," in the newly issued first number of the *Economic Journal*. The first two of these papers are extremely pessimistic in tone; the last, perhaps, errs in the opposite direction. All the papers are likely to promote a feeling of uneasiness, if not even of alarm, among investors in colonial securities, and those who do business in Australia and New Zealand. They represent, from different points of view, the condition of matters, in Australia especially, as tending towards a crisis which might involve a repudiation of debt and separation from the home country. Though such a conclusion is probably overstated, the papers may serve as a wholesome antidote to the inflated accounts of colonial development which are periodically displayed for colonial use and exportation to the home country. The view which these papers give of the Australian colonies is that of a country in which State Socialism has secured complete sway, and in which work organised by the Government is always expected to take the place of private enterprise whenever the latter shows any sign of falling off. According to the two former papers, the result of this policy is that the character of the people has been sapped by the decay of the feeling of individual responsibility and independence.

The working out in the colonies of certain forces now operating in this country and in others whose social institutions are of longer standing than those of the colonies is extremely interesting, since these forces meet with comparatively slight resistance in newly settled countries, and operate there with greater certainty and rapidity than in older countries. Thus the method adopted by the colonial Governments of building railways for public account is proved by the history of Australia to have serious consequences, which are sometimes overlooked in favour of certain immediate advantages. The collection of a great number of men by a contractor to make a railway for a joint-stock company is not generally held to imply responsibility for the maintenance of these men, except during the period and on the terms of the contract between employed and employed. The sudden dispersal of these men when the contract is at an end may, if the numbers be large, produce some economic disturbance in the district concerned, but this, as a rule, soon passes away in the absence of extensive artificial attempts to organise the labour of men for which there has at that particular place ceased to be a demand. In the case of a colonial State railway the collection of men takes place under similar circumstances, but their dispersal is accompanied by a set of conditions different from those with which we are familiar. The men not only claim work from the State, but, under existing laws, make good their claim, and thus the State, having embarked on public works, when these public works are completed, finds itself permanently saddled with the organisation of the labour of the men whom it has been employing. This removal of the unemployed from the labour market has, among other influences, the effect of strengthening the powers of the Colonial trades unions in their efforts to dictate terms to the employers. The Protective tariff, the Factory Acts, and the strength of the trades unions combine to give colonial workmen a position as regards employers, which one of the severest critics of Australian institutions admits is vastly more powerful than the position of American workmen. What, then, according to these critics, is the result of this? The power of the trades unions, exercised in an "unscrupulous, narrow-minded, selfish, and ignorant" manner, deters capitalists from embarking in fresh enterprises, and enhances the difficulty of a would-be employer in obtaining capital wherewith he may embark in business. The argument is that the conditions are extremely favourable for the growth of enormous fortunes on the part of those who have already a footing, and for the protection of these against the competition of newcomers. An incident narrated by one of the critics illustrates this. A partner in a firm in Melbourne asked the advice of a friend in reference to a demand on the part of his workmen for higher wages, or some fresh conditions of employment. His friend advised him to accede promptly to their demands, and, in addition, to present each of them with a gold watch. When asked why he proposed the gift of a gold watch, the friend reminded the employer that the exactions of the trades unions were very useful, in preventing competition in his business, and that he had in consequence only one rival in Melbourne, whereas under normal conditions there was room for half a dozen. The friend added that the men were almost all grey-haired men, who would themselves have been employers if the conditions attaching to the administration of capital were less onerous. This state of matters is said by the critics to be due to artificial conditions which cannot permanently be maintained. The eight hours day is due to the power of the trades unions, and to the consequent absence of competition among workmen. The rapidly increasing growth of a few large fortunes is due partly to the Protective tariff, and partly to the difficulties attaching to the organisation of labour in the colonies; and the conditions generally are attributed to the continuance of extensive borrowing from England. The exaggerated ideas of luxury and of the possibilities of colonial development, engendered at the time of the gold discoveries in 1851, have led, the one to the demand, and the other to the supply, of immense sums of public and private debt, which it is said now amounts to upwards of £300,000,000 sterling. It is not in so many words alleged that the Australians contemplate repudiation, but Mr. Fortescue goes so far as to insinuate that under certain conditions they might think of it. Apart altogether from any prospect of repudiation, however, if it be the case that English money has been maintaining a standard of colonial luxury which for some years the colonists have not been earning, and which there is no immediate prospect of their earning, the outlook is sufficiently serious. There can be little doubt that the publication of these articles will operate injuriously upon Australian credit, and the sooner some apologist arises for the Australian colonies the better. Mr. Fortescue suggests that, under certain circumstances, the appointment of a commission of experts to examine into the finances of Australia may become necessary. No actual corruption is alleged, but the mode in which the accounts are stated is said to be partly unintelligible and partly misleading. Forewarned is forearmed, and although a financial crisis due to the inability of the colonial Governments and colonial banks to meet the claims of their bondholders would be much more serious than the recent Argentine trouble, it might be minimised by taking prompt measures, and by a wise development of the great resources of the Australian colonies.

THE POST OFFICE AND THE BOY MESSENGERS.

The settlement of the Boy Messengers' case is so far satisfactory; but the extent to which the Post Office and other creations of Parliament are interfering to strangle private enterprise is becoming serious enough to justify a drastic re-examination of the whole system. The assumed necessity of conserving for the benefit of the public the possible profits of a few industries, such as letter carrying, electric lighting, telegraphy, telephony, &c., is resulting, not in the acquisition of profit by the public, but in the prevention of profit being earned by anybody. It is absurd to regard the Post Office and the Board of Trade as fetiches which must not be touched. The management of these institutions—the first, certainly, of a positive and useful sort; the second, of a wholly negative and obstructive order—must sooner or later be thoroughly overhauled. While it is comfortable enough for those whose businesses are not likely to be touched by this pottering in pseudo-socialistic legislation, the system is depriving the public of the benefits of invention, and placing an embargo upon the development of industry. It is not too much to say, as regards the Post Office, that no improvement of great moment has been effected since the adoption of the penny post fifty years ago; and that such improvements as have been effected have been forced upon the Department by external pressure. As regards the Board of Trade, it exists almost wholly for the purpose of preventing other people from conducting their business, or at least for placing as many obstacles in the way of their doing so as possible. The old notion of the duty of a Government was that it should foster the industries of a country, and Governments did so by clumsy enough protective and other methods. Yet these methods were always intended to benefit industry. Now Governments exert themselves to devise means to choke industry as effectively as they can. Before they entirely succeed, it is worth while asking whether it is not possible to put a stop to the tendency, and to free some of the suffering industries from the thraldom of Governmental interference. It is to be noted that this interference is directed, not exclusively towards the saving of life and such worthy objects, but is also directed towards strangling present industries with the view of annexing the profit of the future. From the narrowest view it must be seen that an industry must grow to be profitable, and that if it be suppressed at its birth it cannot grow at all.

THE PROPOSED FORTH AND CLYDE SHIP CANAL.

It is quite evident that the scheme for the proposed Forth and Clyde Canal, which we described briefly in our issue of the 13th ult., will not be allowed to occupy the field alone, and it is well that the alternative schemes should be discussed. That put forward by Messrs. Stephenson, of Edinburgh—namely, the Loch Lomond route—has not been kept before the public to such an extent as the other, but it is quite evident that its supporters and promoters are not allowing their project to be forgotten. At the recent Convention of Royal and Parliamentary Burghs held in Edinburgh, a resolution was unanimously carried to the effect, "that in the opinion of this Convention, the construction of a ship canal between the Firths of Clyde and Forth is of national importance, and a scheme for carrying it through should be supported by Government, with a view to the development of trade and commerce, and as an addition to our means of home defence"; and it was remitted to a committee with powers to adopt such means as may be expedient to give effect to the resolution. Curiously enough, a very similar resolution was discussed by the Convention 127 years ago, and it was greatly, if not entirely, owing to its action and advocacy that the Forth and Clyde Canal was formed in its present course and at its present depth, and the mover of the resolution said that if the members of the Convention had

Digitized by Google

inherited the wisdom and enterprise and the public spirit of their forefathers, they would agitate for a large ship canal suited to the present day requirements of our Navy and mercantile marine. Of the various schemes which were proposed only two were thought advisable. The Loch Lomond route, started from Grangemouth to near Alloa, and throughout the canal would be 30ft. deep and 72ft. wide at the bottom. From the lock at Alloa the canal would traverse the valley of the Forth, *viâ* Stirling, till it reached high ground and the watershed of the Endrick, and entered Loch Lomond close by the mouth of that river, and a cut would be made to Loch Long. The total length of the canal was 54¼ miles, and its estimated cost £8,000,000. There were no engineering difficulties of any serious kind about the construction, and, although more roundabout than the other scheme, it had the countervailing advantages of a low level throughout, and of an inexhaustible reservoir of water in Loch Lomond to supply its locks. The other route, which we mentioned in our recent issue, is the direct route from Grangemouth to Yoker. It has not only the advantage of being the shorter route, but of striking the great commercial emporium of Glasgow and of passing through a rich district of mineral resources and with many established industries. On the other hand, it had the disadvantages of a high level and of requiring twelve locks, thus causing tedious delays in the passage of ships. The mover of the resolution did not ask the Convention to express any opinion on the relative merits of the two routes, but confined himself to the general question, as he thought that the capitalists who invested their money, or the Government, by means of a Commission, would settle the route to be followed. He was of opinion that if the Government were to guarantee 2½ per cent. on the estimated cost of eight millions, the work would certainly go on. The annual amount of the liability under the guarantee would only be £200,000, and he did not believe that the Government would ever be called upon to pay it. The recent action taken by the Associated Chambers of Commerce, combined with that of the Royal Convention of Burghs, should at least ensure a thorough investigation of the whole subject, and we trust that sufficient interest will soon be exerted regarding it to justify the appointment of a Royal Commission.

Letters to the Editor.

THE USE AND ABUSE OF MATHEMATICS.

To the Editor of "Industries."

Sir,—A friend has asked me to add something to the correspondence in your columns on the subject of "The Use and Abuse of Mathematics" as regards engineering. For over twenty years my work has combined the mathematical and the practical, and, therefore, possibly my ideas on this subject might not be wholly without interest to some of your readers; but I can express them in a letter, of course, only very briefly.

1. Every one who is at all reasonable will agree that a knowledge of pure mathematics combined with ignorance of practical matters is pernicious. It is not only useless and not only harmful in the sense that the time spent in acquiring it has been wasted, and has been withdrawn from the time that ought to have been spent in acquiring a sounder sort of ability—that is, its evil effect is not only negative; it is positively injurious, in perverting the whole habit of thinking and of acting.

I have used the phrase "practical matters," as I often do designedly, for the sake of catching the attention of the so-called "practical man." But let me explain that I mean by knowledge of practical matters, simply knowledge of all kinds of *fact*. This includes all that is definitely and certainly known of physics, chemistry, geology, and other natural science, as well as the mechanical practice of the workshop or of the field, the social and disciplinary organisation of industry, and the economic and financial operations of trade. I do not mean, of course, that a man should make his knowledge of "practical matters" *complete* before he begins to make use of mathematics. If that were to be the rule, he would never use mathematics, as this complete knowledge is quite unattainable in a life-time. What I do mean is that, he should not use mathematics to study or to originate theories on any subject before he has made himself fairly well acquainted with the practical facts of that subject.

2. I think that a merely elementary knowledge of formal mathematics is, perhaps, worse, as far as regards engineering, than no knowledge at all. If arithmetic be considered an elementary branch of mathematics, I make an exception of it; to be an accurate, quick, and rational arithmetician is of incalculable value in every class of engineering work, as also of every other kind of work that is quantitative. Some elementary portions of constructive geometry (not Euclid nor the so-called descriptive geometry!) might be excepted along with arithmetic—such portions as are of real help in genuine practical quantitative work, but which do not lend themselves to encourage a theorising tendency.

Nothing is so common as to find that the real objection of the "practical man" to the mathematical treatment of a subject is wholly based upon his own inability to understand it, and to find that almost at the same moment in which he inveighs with lofty scorn against the complete (and therefore *necessarily* complicated and in a certain degree difficult) mathematical solution of a problem, he will himself offer, with a delightfully cocksure manner, a solution involving only the simplest mathematical forms (which in itself would be a valuable characteristic), but which labours under the disadvantage that it leaves out of account at least half of the most important practical facts of the case.

Is it not absurd that most of our mechanical text-books devote pages and pages to extremely clumsy dodging of the differential and integral calculus? Nearly all our mechanical theories—even the most certainly true, the most commonly known, and the most necessary for practical design—are based upon the methods of the differential and integral calculus. But in order to encourage elementary pupils to undertake the task of understanding these theories, the fact that they are so based is concealed from them, and the students are subjected to long rigmaroles of roundabout, tautological, and occasionally illogical reasoning to arrive at results which can be obtained with infinitely less labour by a more rational process.

For the understanding of all the essential elementary problems of engineering, only the elementary parts of the calculus are needed. Why is it not more commonly known that these elementary parts, if properly taught, for instance, by graphic methods, are much easier to learn than the middle and latter parts of the algebraic and trigonometrical text-books used in our lower-class secondary schools? Why should schoolboys be compelled to learn the difficult and useless parts of geometry, algebra, and trigonometry before they learn the easy and useful parts of the calculus? The only reason is that the school examiners will allow no departure from an antiquated and thoroughly rotten system of education.

3. I would advocate the division of mathematical training into three stages, as follows:—

A. The development of informal but clear and accurate ideas regarding the geometrical relations of space and quantitative relations, and the simultaneous development of the ability to reason about these correctly and logically; but this, without the aid of any sort of conventional symbolism—that is, without diagrams or projection drawings, without letter or other symbols, and without algebraic equations—with no other aid but *models* and *talk*. If a scholar never got beyond this stage, but went through this part of the training alone successfully, he would be infinitely better equipped for his whole practical life-work than the other scholar who has learnt in the usual formal way the books of Euclid, algebra "up to the binomial theorem," and the ordinary school trigonometry.

B. Constructive, plane, and solid geometry on the drawing board, and all sorts of mathematics that can be taught and practised graphically on the drawing board. This includes rectilinear and curvilinear plane constructions, projections of solids, and a great deal of mechanics.

C. The development of mathematical reasoning by help of the conventional systems of algebra, trigonometry, and the calculus.

This system of training would not only give the best possible results when completely carried out, but it would have this incalculable advantage, that, if broken off at any stage, the part already received would yield lasting beneficial results of a perfectly sound kind. It would produce no tendency towards specious mathematical showiness without real knowledge and ability to back it up, and it would produce no inclination to indulge in imaginative theory not based upon fact.

4. I think it ought to be recognised that the even approximately exact solution of the important problems in engineering practice involves mathematical ability of a high order, both in the direction of being familiarly acquainted with mathematical methods and operations, and also in the possession of sound and careful reasoning power regarding the quantitative aspects of physical phenomena. An engineer who devotes himself to practical work, as he must do if he is to get on in his profession, has not time to make himself the possessor of first-class mathematical knowledge such as is necessary for original work in the solution of such difficult problems. It must, therefore, always remain a matter of individual judgment and taste how far each engineer should devote time to perfecting his mathematical ability, because he can only do so at the expense of losing so much opportunity for the gain of practical experience. But this much is clear, that everyone who intends to take a place in the front rank of his profession must cultivate his mathematical ability so far as will enable him to comprehend and to form an intelligent judgment upon the work of others who devote themselves to original investigation in this direction. Moreover, it would be very desirable that these latter should not be discouraged in their very legitimate work by the jeers and derision of the ignorant mob of inferior "practical" men—*i.e.*, men who are ignorant of everything but rule of thumb. Truly practical men will rather seek to assist the genuinely able theorists by maintaining a free, friendly, and respectful communication of ideas between the two classes of workers. I am glad to believe that such has always been the relation between the best practicians and the best theoreticians. I am able to express these last opinions quite unreservedly, because, although I have done a little theoretical work which may possibly be found useful, I myself am very deficient in mathematical knowledge, and have continual cause to regret that, being now in the position I occupy, I did not in my young days advance my mathematical studies several steps further than I actually did.

Yours, &c.,
Robert H. Smith.

Mason College, Birmingham,

THE INFLAMMABLE LIQUIDS BILL.

To the Editor of "Industries."

Sir,—The announcement which appeared in your last issue was received with much pleasure by those of your Scotch readers who are interested in the mineral oil trade, for those who were responsible for "The Inflammable Liquids Bill" seemed to have altogether overlooked the distinction between burning oil of Scotch manufacture and American and Russian petroleum oils. So far as I have been able to learn, Scotch-made oil, which has flashing points varying from 120° to 125° Fahr., has not, during the thirty years it has been in use, been the primary cause of any serious fire or accident while stored in large or small quantities. Accidents have been almost invariably caused by the use of defective lamps, and very often by the upsetting of the same in a drunken brawl, which, of course, legislation is powerless to prevent. In Scotland, petroleum oil, which has a minimum flash-point of 73° Fahr., is almost unknown, and it should therefore be dealt with independently of Scotch oils. In fact, in my opinion, the Bill is to a very large extent unnecessary, as the Petroleum Act of 1879 fully provides for the protection of the public in the conveyance, storage, and handling of petroleum, from which nearly all the fires connected with storage have arisen. The effect of that Act has been to curtail the petroleum spirit trade by one half, and it has practically put a stop to the use of spirit or benzoline or sponge lamps.

If the proposed Bill had become an Act of Parliament the trade in lamp oil would have suffered a like diminution. Moreover, its whole provisions are of an exceptionally harassing and inquisitorial character, and so onerous and intricate as likely to defeat their aim by becoming inoperative—at least, the only other alternative is the ruin of the trade. The provisions of the Bill not only harass producers and distributors, but also add unnecessarily to Imperial and local taxes, by creating a large array of inspectors and other officials, whose chief object seems to be to magnify their offices and render the lives of ordinary people as miserable as possible. Of course, all this means that the price of oil would be increased to the consumer. As a Scotchman, however, I wish to protest chiefly against the effects the Act would have on the Scotch mineral oil trade. It is true that in the Bill a slight concession was made in favour of high test oils, in excluding from its operations oils flashing not under 150° Fahr., but to show how irrational and absurd the concession is the oil must not only flash over 150° Fahr., it must also have a specific gravity not less than ·840, whereas it is well known that lighthouse oils, marine sperm, and mineral colza oils have flash points much over 150° Fahr. and a specific gravity much under ·840. I hope if ever the Bill be reintroduced that its framers will study a little more carefully the conditions and requirements of the Scotch mineral oil trade, and not harass an industry which has been of immense benefit to the working classes.

Yours, &c.,
Paraffine.

Glasgow, 18th April, 1891.

THE LABOUR COMMISSION.

To the Editor of "Industries."

Sir,—The experience of the past certainly justifies the opinion with which you open your leading article on the Labour Commission—namely, that when the Government desires to shelve an inconvenient question, the appointment of a Royal Commission is a favourite expedient. The results of the previous Commissions you mention have not been very great, but still it must be confessed that the indirect results have been considerable, as they have educated public opinion on the points at issue, by the collection and publication of a large mass of information regarding them. I think this fact points to a method whereby special Commissions would be to a large extent rendered unnecessary—that is, by the adoption of the suggestion made by Sir John Gorst in the speech which he delivered shortly before the announcement of the intention of the Government to appoint the Commission, and which at the time was looked upon as a sort of preparatory kite sent up to ascertain the state of public opinion on the subject. Sir John pointed out that almost every foreign country had a Ministry of Industry, and expressed the opinion that one of the reforms which ought to be insisted upon in this country was that there should be some Department specially to look after the interests of the working classes. I would prefer to put the matter on a broader basis, and say that the Department of Industry should look after the interests of all sections of the industrial classes, workers and employers alike, and that it should collect information on all points of interest and receive evidence from all parties who were likely to throw any light on any part of the labour problem.

Possibly the most tangible result of the Labour Commission will be the formation of such a Department of Industry, for the evidence which is certain to be placed before it will show the advisability of collecting that class of information in a more systematic manner than hitherto. Trade statistics of a more definite character in the different departments than we at present possess would have the effect of steadying employment, and possibly of indicating a remedy for those out of work, and thus help to solve the difficult problems connected with periods of trade depression.

The Department might also take charge of the arrangements connected with arbitration and the settlement of trade disputes generally, and all the proposals connected with these questions. The hours of labour in different industries and occupations, the scope and results of the Factory Acts, the employment of women and children, and all questions connected with the health of the different classes of works would come in for attention.

Another matter, which ought at least to be investigated by the Department, is the scope of Government interference in special departments of industry, when these tend to become monopolies. In these days of syndicates, trusts, and "rings," it may soon be necessary at least to have a policeman on the Board of Directors to look after the public interests. If the Commission results in nothing beyond an efficient Intelligence Department of Industry, it will have done good service, and paved the way for further developments.

Yours, &c.,
Economist.

Leeds, 18th April, 1891.

ENGINEERS IN THE ROYAL NAVY.

To the Editor of "Industries."

Sir,—Your correspondent "A. E.," who writes from Portsmouth, is of opinion that the writer of the article which appeared in your issue of the 27th ult. had little experience of the Royal Navy, and that without much experience it is almost impossible for any one thoroughly to appreciate the conditions of the service. He seems to forget, however, that men who know the general requirements of ships of war, but who have not been in the naval service, are likely to form a more unbiassed opinion as to its real requirements than those who have grown up in it and imbibed all its prejudices, and its rather narrow manner of looking at things, and if I may, without discourtesy, venture an opinion on the subject, I think your correspondent is not free from those prejudices.

Digitized by Google

As a marine engineer who is acquainted with the requirements both of the Navy and the mercantile marine, I decline to admit the correctness of the picture your correspondent draws of the relative duties of chief engineers in the two services. A modern first-class passenger ship requires almost as much ability on the part of its engineers, if not more in some cases, as at least the average man-of-war, and almost without exception these men have worked their way from the workshop through the various grades till they have reached their present responsible positions. In fact, to begin with, they were "artificers," but with the prospect of bettering their position if they showed that they had the material in them, they set about it in good earnest, and the results in many cases have been most satisfactory. The notice of the late Mr. Bryce-Douglas, which immediately preceded "A. E.'s" letter, was rather a curious commentary upon it. Mr. Bryce-Douglas was a joiner to begin with, and after a comparatively short experience as a mechanic or artificer he had rather a rough time of it for a great many years, but yet he developed into a leader of men and an accomplished engineer. Surely your correspondent will admit that if he had been induced to enter the Navy he would have turned out an ideal engineer officer, and one who could keep his men in their proper places and his engines in good order.

I quite agree, therefore, with the opinion expressed in your article that for the best of the engine-room artificers some avenue ought to be opened up whereby they might be able to obtain the position of engineer officers, and also with the more general opinion that, in every service, unless men get a chance of rising there will be discontent and difficulty.

With regard to the mathematical requirements of the Admiralty, whoever may be nominally responsible for the papers set, it is quite evident that the actual work falls largely into the hands of teachers, who set too high a standard. While I have no wish to depreciate the value of mathematics, I do say most distinctly that it would be possible to get thoroughly efficient engineers whose knowledge did not extend much beyond arithmetic and the most elementary parts of mathematics. Even the elaborate duties pictured by your correspondent require a larger percentage of common sense and experience than of mathematics. The mistake, which is too often made at the present time, is to suppose that education is only to be got from books or in schools or colleges, which, in my opinion, too often produce either pedants or prigs.

Your correspondent remarks that the Navy is a peculiar service. On that point there will be little difference of opinion. A service must be very peculiar when its best men leave it on the earliest opportunity, and when young men cannot be induced to enter it, and I think your article very justly indicated how some of its peculiarities could be got rid of.

Yours, &c.,
M.I.N.A.

Glasgow, 18th April, 1891.

PATENT LAW IN GERMANY.

(From our Berlin Correspondent.)

A carefully drafted proposal for an amendment of the patent law of 1877 has been recently passed by the Reichstag, after having been read three times, and will come into force on the 1st of October next. The chief point to be noticed in the new law is that the examination of patents with regard to novelty is not to be abolished. The new law does not decide what amount of invention is patentable, so that this question must be settled in each case by the Patent Office as heretofore. Publication, if made more than a hundred years ago, is not to act in anticipation of a patent. Patents taken out in foreign countries are to act in anticipation against the inventor, and those claiming rights under him, only after a lapse of three months, and thus an extended period of time is allowed by the Act for an application for a patent in Germany. If an invention is stolen from another person, and an application for a patent has been made, the inventor is able not only to oppose the granting of a patent to the applicant, but to obtain a patent for his own application. The patent fees may be paid for the whole duration of a patent in advance, so that the lapse of a patent through delay in the payment of fees may be rendered impossible. If a patent on which the full fees have been paid should be afterwards annulled, the fees will be returned to the patentee. An application for the annulling of a patent shall not be made when the patent has been in existence more than five years. For the determination of this point, however, a period of three years is provided. The very high fees now payable for a German patent have not been diminished by the new Act, but it is provided that such a lowering of the fees may be made by order of the Federal Council. The important provision that a patent may be revoked after the expiration of three years if the patentee fails to carry out his invention in Germany to a suitable extent, or at least to do everything that he can to carry it out, remains in force, and should be particularly noticed by foreigners. The organisation of the Patent Office is to be so regulated by the new Act that there may be greater security for a proper and efficient examination of patents. Before an application is refused, the applicant is to have an opportunity of answering objections to the granting of a patent. If he should fail to obtain a patent, he may then support his claim by oral evidence. At the preliminary examination expert witnesses may be called, and a statement of the various attempts which the inventor had made may be presented. If the decision of a judge puts a new aspect on the case, the applicant is to have an opportunity of answering any objection raised. A proviso, which is of great importance to chemical industries, is that where proceedings are taken to patent a new material, every material of similar manufacture is regarded as included in the claim until proof to the contrary is shown. The damages payable for the infringement of a patent have been increased. The Patent Office has been established at its new building since the beginning of this month. This new office is in every respect suitable for its purpose, whereas the old one was too small. The public obtain a great advantage from the new arrangement, since the important technical library is now open to all persons from 9 a.m. to 9 p.m. Only a provisional trial of the new arrangement has yet been made, but in view of its great utility and the many expressions of opinion in its favour the authorities will probably continue to grant this privilege.

LIGHTHOUSE ILLUMINANTS.

We have noticed from time to time the contest which has been going on between Mr. Wigham and the authorities who are responsible for the management of our lighthouses, and have admired the vigour and perseverance displayed by the former. He does not seem to be much discouraged by the Report of the Special Committee appointed to investigate the subject, but on the contrary seems to be determined to keep on making improvements on his method of lighthouse illumination. At a meeting a few days ago of the Royal Dublin Society, Mr. Wigham described two important improvements which he has recently devised. One of these is a burner, by means of which gas made from ordinary coking coal can be so enriched by hydrocarbons and by a supply of heated air, as to produce an illuminating power practically double that of the most powerful gaslight now used in lighthouses.

The other improvement consists in a new arrangement of dioptric apparatus, by which lenses of larger surface and greater focal distance than those at present adopted can be used in lighthouses, and thus their power be enormously increased. Mr. Wigham exhibited one of his new burners, and showed by experiment that its power is double that of the cannel gas burner now used, and therefore equal to about 6,000 candles. He also pointed out that if this burner was used in connection with the arrangements of lenticular apparatus, which he described, a power could be evoked for the benefit of the mariner in foggy weather equal to about 8,000,000 candles, which, owing to the composition of the gas light and its great volume, would have an effect upon fog or haze very much greater than that of the most powerful electric light. It would have a much greater intensity, being six times as powerful as that of Tory Island, which is the largest lighthouse flash in the world. From these experiments it is evident that we have not yet heard the last of the contest between Mr. Wigham and the lighthouse authorities.

THE PREVENTION OF SMOKE IN LONDON.

At the last weekly meeting of the Balloon Society, Mr. W. H. Le Fevre, C.E., President, read a paper on "The Public Health (London) Bill, 1891," with special reference to the prevention of factory smoke.

The Chairman, in introducing the lecturer, said that there was no question at present before the public on which opinion was so unanimous as on the smoke question. The members of the medical profession had persistently, for many years, impressed upon the public that pure air was essential to good health and long life, while impure air was detrimental to health and productive of disease. He ventured to say that they had supported this statement with an immense amount of evidence which was incontrovertible. He did not require to say one word in support of the proposition that smoke was a nuisance; they were all at one on that point. What they were not agreed about was the way to get the nuisance abated. He was quite sure they would all hail with satisfaction anything that tended to the abatement of the smoke nuisance.

The author stated that there were no less than nine Bills now before both Houses of Parliament relating to burials, factories and workshops, sanitation, the smoke from furnaces and fire-places, and generally to public health; and he referred at some length to Sections 21 and 22 of the Public Health (London) Bill, 1891, which related to the prevention of smoke.

Much had been done, he said, to solve the problem of complete and smokeless combustion, and many manufacturers had availed themselves of several inventions at considerable cost. The production and use of gas for manufacturing purposes, and the automatic feeding of fires by mechanical stokers, economised manual labour, and effectively and profitably caused coal to be burned as fuel. The Vicars stoker seemed to best comply with practical requirements, and was in operation in the principal works in London.

The author then proceeded to describe the various systems of mechanical stokers, explaining the results obtained—viz., abundance of steam generated by the use of the most inferior fuels, and the absence of the smoke nuisance.

After the reading of the paper, Mr. Atkinson, the mechanical engineer to the London County Council, moved the following resolution:—"That in the opinion of this meeting the Public Health (London) Law Consolidation Bill is entitled to our support, so as to secure the proper sanitary condition of all premises within the district; and further, this meeting trusts that the Act may come into operation the 1st day of January, 1892." He said there were several appliances tending to promote the object they had in view, but from his own practical experience he advocated the adoption of Vicars mechanical stokers. In the North of England factories were the greatest sinners in the production of smoke.

Mr. G. L. Dennis seconded the resolution, and stated he was of opinion that they were suffering more from the result produced by domestic fire-places than from factories.

Major Cresswell and other speakers supported the resolution.

Afterwards Mr. W. R. Merrett moved, and Mr. E. C. Keevil seconded, the following resolution:—"That in the opinion of this meeting the Public Health (London) Law Consolidation Bill, as far as regards Sections 21 and 22, should be extended to all parts of the United Kingdom of Great Britain and Ireland."

Both resolutions were carried unanimously.

Reviews.

The Economic Journal, The Journal of the British Economic Association. Edited by F. Z. Edgeworth. London: Macmillan & Co. 1891.

The British Economic Association has been established for the purpose mainly of providing an organ of the most eclectic order for the promulgation of views on economic subjects. The intention of the Association is to include all shades of economic opinion, and this is undoubtedly a wise resolution, since the whole subject is just now in a state of flux, in which it would be hard to say what is orthodoxy and what is not. The names of the contributors to this and succeeding numbers of the quarterly journal, are evidence enough that the journal will be a really important addition to periodical literature. The first issue fulfils this promise. Many of the articles are of exceptional value, and are varied and interesting enough to attract even the general reader. "The Eight Hours Day in Victoria," "The Difficulties of Socialism," and "The Boycott as an Element in Trade Disputes," by Mr. John Rae, Mr. Leonard Courtney, and Mr. John Burnett repectively, deal with labour questions; "The Fall in Silver," by Mr. Henry Hucks Gibbs, now M.P. for the City of London, with currency; and the remainder of the major articles with theoretical questions mainly. Among the notes and memoranda are excellent notes on Trade and Finance in 1891, and on the recent Baring Crisis, and a note on the Scottish Railway Strike by Professor Mavor.

Elementary Systematic Chemistry. By William Ramsay, F.R.S. London: J. & A. Churchill. 1891.

A new elementary chemistry nowadays is only justified if it marks a new departure in the method of treatment, and in this respect Professor Ramsay's book warrants its existence. There can be no doubt that the scheme which the author has adopted will, as he hopes, help to demonstrate the value of chemical study as a training in classification and as a means of developing the reasoning powers. It is, however, open to debate whether an elementary chemistry for the use of schools and colleges should only have this object in view. We believe that, although such a demonstration may induce some elementary schools to give a greater attention to chemical teaching in the future, this end may be more rapidly attained by urging the value of chemical knowledge for the sake of its general utility and applications to everyday life. We are afraid, however, that the present state of our knowledge is not sufficiently advanced to enable

Digitized by Google

us to so systematise chemistry as to prevent it from discouraging the young student, and that converts to its study are more likely to be obtained by the old-fashioned methods of experimentally showing a few facts, unconnected, as they often are, concerning common things, than by plunging into the sweeping generalisations of the periodic law. Notwithstanding the enormous help that the development of this law has given to chemists towards grasping the interactions of the elements with each other, we are still far from a complete explanation of the formation of the greater number of chemical compounds. As the periodic law has had little to do with the historical development of chemistry, and as our knowledge of the constitution of complex organic bodies has been determined almost independently of it, it appears somewhat premature to insist too much upon its value. The author, no doubt, is looking ahead to the time when we shall know what the periodic function is. At present, our want of knowledge on this point makes the classification difficult to appreciate except in the chapters devoted to the consideration of the elements, their halide compounds, and a few other simple groups consisting of compounds of two elements. For compounds containing more than two elements the classification seems to be very laboured, and the author's views on double salts do not diminish the difficulties which continually present themselves. When our knowledge of the elements is such as to enable us to say, for example, that the two compounds $AlF_3 3NaF$ and $AlCl_3 NaCl$ could have been predicted, then a classification based on such knowledge would, no doubt, allow every compound, whatever be its complexity, to drop into its allotted place, and we should be prepared by our theory to find free NH_4 described in the chapter on the principal halides of the elements of Group 1, milk of sulphur under ammonium sulphide, sodium hydride Na_2H as the first-mentioned important alloy, and so on. The author's faith in the unknown function leads him, when speaking of the evolution of oxygen on the addition of cobalt nitrate to bleaching powder, to say that the part played by the cobalt is not yet fully understood, and thus bids us look forward to the time when the theory will enable a student to calculate, from the position of cobalt among the elements, how its nitrate will react when warmed with bleaching powder.

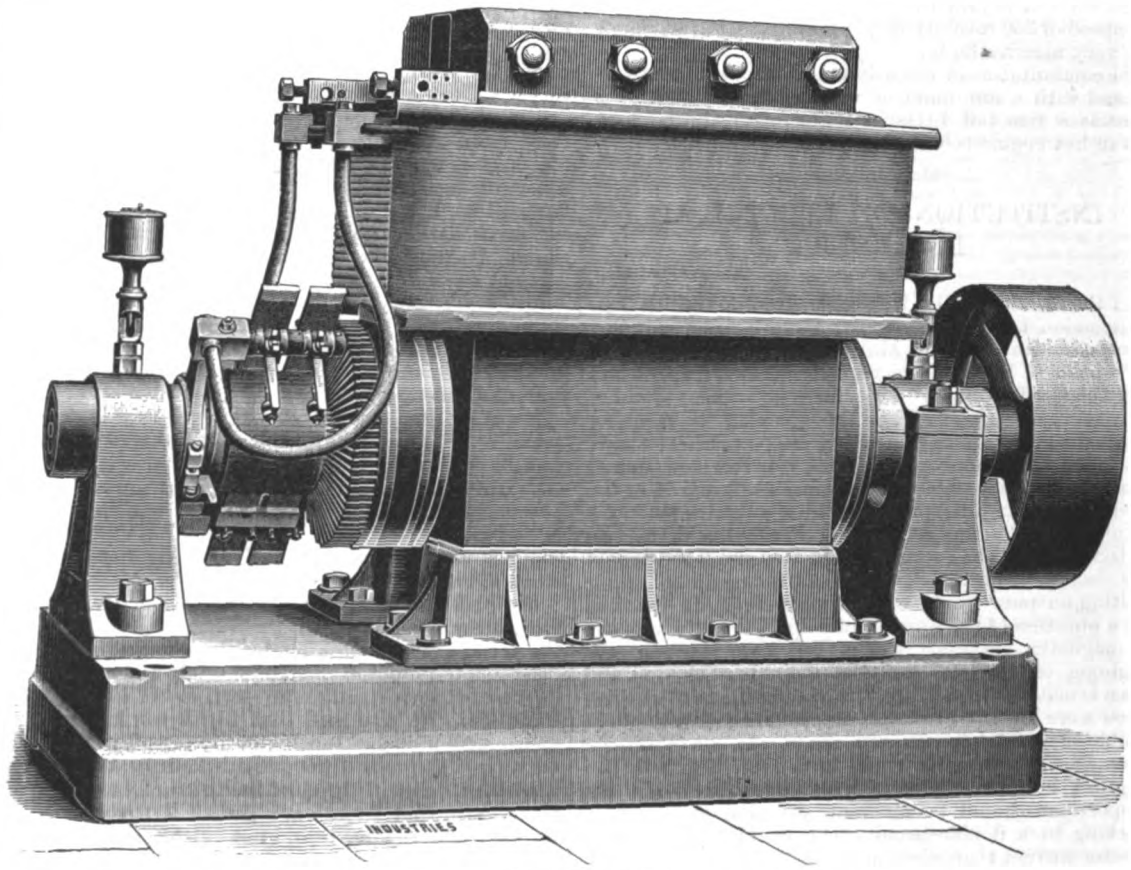
Bibliotheca Polytechnica: A Directory of Technical Literature. First Annual Issue. London: Sampson Low, Marston, & Co. 1891.

This seems a complete and well-classified catalogue of books and journals relating to the various branches of technical literature. The subject headings are given in three languages, German, French, and English, and the usefulness of the catalogue is increased by the numerous cross references, which enable a person seeking information in any special branch to find at once the general subject heading under which it is classified.

Potts' Mining Register and Directory for the Coal and Ironstone Trades of Great Britain and Ireland, 1890.

The present volume is the third annual edition of a reliable statistical and literary work in connection with the coal and ironstone industries of the United Kingdom, which, while compressed into reasonable compass, forms a complete manual of reference to the industries named. Though no new features have been introduced the whole of the information contained in the previous volumes has been carefully revised and brought up to date. In this issue appears the third chapter of a treatise on the theory and practice of mine ventilation, and, dealing with various phases of the incidence of natural and artificial ventilation, forms a valuable addition to the literature relating to the complex questions involved, and deserves to be carefully studied by mining engineers. From the variety and completeness of the information it contains the book should find a place in all colliery offices.

Geometry of Position. By Robert H. Graham. London: Macmillan & Co. 1891.



"Geometry of position" as a distinct branch of geometrical science is comparatively modern, and has not, previous to this treatise, received separate treatment in any English work. It may not inaptly be defined as the theory of that branch of geometry of which graphic statics is the practical application, in evidence of which its study has been made a compulsory antecedent to applied graphics in many Continental technical institutions. The author has previously published a work on "Graphic and Analytic Statics," and now issues the present short treatise as an honest attempt to popularise what he believes to be an interesting and useful study. It is essentially a book for the mathematical and theoretical student; and from the style of the text, together with the set of exercises appended to each chapter, we should imagine it is primarily intended to rank as an engineering text-book; when that position is accorded it, and its subject matter is included in the curriculum of studies at our technical colleges, we think it will find its most suitable sphere.

Practical engineers will not find it sufficiently popular, in its precise language, its laborious nomenclature, and dependence upon mathematical demonstration, to make it easy reading, nor does its contents appear to lend themselves readily to practical application. We may, however, direct attention to an example in Chapter II., where the author applies the principles of projective conics to determine the relative angle of advance in an automatic valve gear, without, however, giving sufficient details to show how the results were obtained, or their practical bearing; and to the application of the funicular polygon in Chapter IV. to find the centre of gravity of an irregular area such as a rail section. The examples of roof truss, bridges, and girders selected for consideration are well chosen so as to present important features, and will be familiar to students of graphic statics, the important addition being that the constructions are followed by geometrical and mathematical demonstration. A large number of connected propositions and theories carefully worked out are included in the text, and the work is evidently one on which much labour and pains have been expended.

Mineral Resources of the United States: Calendar Year 1888. Washington: Government Printing Office. 1890.

This statistical report on the condition of the mining and metallurgical industries of the United States is the sixth of the series issued under the supervision of the United States Geological Survey, the period covered being the calendar year 1888. Owing to the delay in the publication of this report, it is unnecessary to allude in detail to the principal statistics, as they have already been published in *Industries*. This work, covering 652 octavo pages, and handsomely bound in cloth, is published at a very low price, and thus compares very favourably with the cumbrous paper-covered blue-book issued at prohibitive prices by our own Inspectors of Mines. The whole work is edited by Dr. D. T. Day, but several important sections have been entrusted to specialists. Thus the section on iron has been written by Mr. J. M. Swank, the general manager of the American Iron and Steel Association, and Mr. F. F. Chisolm. The sections on copper, lead, and zinc have been written by Mr. C. Kirchhoff; those on manganese, petroleum, natural gas, and coke by Mr. J. D. Weeks; that on precious stones by Mr. G. F. Kunz; that on aluminium by Mr. R. L. Packard; that on structural materials by Mr. W. C. Day; and that on coal (230 pages) by Mr. C. A. Ashburner. The total value of the minerals produced in 1888 was £116,910,135. This enormous figure serves to illustrate the immense amount of labour involved in the collection of these statistics. Valuable aid would, of course, be furnished by associations of manufacturers, but the bulk of the returns resulted from direct application to the producers, and it is pleasing to note the spirit of co-operation which renders a report of this kind possible.

SIEMENS' DYNAMO.

General View.

We illustrate above a compound-wound dynamo with drum armature, of Messrs. Siemens' latest type. In this particular machine Messrs. Siemens have used wrought-iron field magnets of a somewhat smaller cross-section than those adopted by many makers, and have wound the series wire on one limb only. This makes the connections simpler, and produces practically the same result as if it were wound partly on each limb. The armature is built up of iron discs, and the conductors consist of strands compressed into rectangular bars, which are arranged round the outside of the armature in the usual way. The end connections are made by the Siemens method, and means have been taken to secure more perfect ventilation. The underneath type of dynamo shown in the illustration has the advantage that massive brackets and framework are not required to secure steadiness of running, and it also relieves the bearings of the great pressure to which they are subjected in dynamos where the armature is on the top, while in a properly constructed machine the proximity of the bed-plate to the magnetic poles does not injuriously affect the efficiency. By varying the supports of the armature and magnets, this design of dynamo can be readily adapted for coupling direct to any type of steam engines, such as Brotherhood's, Chandler's, Willans', or the ordinary double-acting kind.

Dynamos of this construction have been supplied by Messrs. Siemens for the St. James's and Pall Mall Electric Light Station at Mason's Yard, the Whitehall Station of the Metropolitan Electric Supply Company, the Westminster Electric Supply Corporation, the central station of the Bradford Corporation, the Liverpool Electric Supply Company, and many others for public and private installations. At the Royal Naval Exhibition they will shortly have running for illumination of

Digitized by Google

the buildings and grounds, in addition to an alternator and some smaller machines, three shunt-wound dynamos of this description coupled direct to Willans I I I engines, each capable of working up to 1,500 amperes at a pressure of 120 volts. The armature is 24in. in diameter, and runs at a speed of 350 revolutions per minute within a magnet with very massive limbs.

The commutators of these dynamos run without sparking and with a minimum of wear, while the machines themselves rise but little in temperature during long runs in hot engine-rooms.

INSTITUTION OF ELECTRICAL ENGINEERS.

At the meeting of this Institution held on the 9th inst. a discussion took place on Mr. Esson's paper, entitled "Notes on the Design of Multipolar Dynamos."

Professor S. P. Thompson regretted that Mr. Esson had used the word "volume" for something which was not of the nature of *volume*, and he thought that the meaning assigned to it was not the *ampere turns* on the armature, but twice that number. He said a better comparison would have been obtained by considering Fig. 4 in the paper to be a two-pole machine with a double magnetic circuit, both the top poles being N (say), and the two bottom ones S. The surfaces of the two armatures would still be the same, and, so far as he could see, their limiting outputs would remain unaltered. It was thus not a question of the number of poles, but of the number of magnetic circuits. Again, relations between the "volume of current" and the diameters of ring and drum armatures were given, but no mention as to whether these were intended to apply to machines with single or double magnetic circuits was made. In his (Professor Thompson's) opinion it would have been better to distinguish between the two types, for he believed the proportions should be different, and that an armature working in a double-circuit field could safely carry a greater current than when in the field of a single magnet.

Mr. Kapp, speaking of the laminated pole pieces mentioned by Dr. Thompson, said Mr. Joel adopted a similar plan in 1885, with the idea of getting more corners on his magnet, and consequently obtaining a greater magnetic pull. He himself had also designed multipolar machines with a deep slot in the middle of each pole piece, and found that the armature reactions were halved thereby. In comparing bi-polar machines with multipolar ones, he pointed out that it was necessary to make the armatures of the latter machines larger, in order to obtain sufficient space between adjacent pole pieces. This, together with the fact that only shallow armature cores are needed, makes the ventilation of multipolar machines very much better than bi-polar ones. This point, he thought, had been overlooked by the author.

Mr. F. V. Andersen remarked that Mr. Esson's formulæ for the load which could be safely carried by armatures without sparking did not include the number of commutator segments. He thought that increasing the number of such segments tended to diminish sparking, and inquired whether sparking could not be prevented by this means.

In the continuation of this discussion on the 16th inst., Mr. F. V. Andersen, in supplementing his former remarks, said that Mr. Esson's formula for the limiting currents was doubtless true if the brushes be at the polar tips; this, however, meant a considerable lead, and a change of, say, 10 per cent. in the load would necessitate the readjustment of the brushes. For central station work it was desirable that machines should have a very small lead, and this could be obtained by having long powerful fields.

Mr. Housman said that the whole of the author's argument in favour of multipolar machines depended on the length of the air space necessary to prevent sparking being generally greater than that required for the copper. Referring to the limiting non-sparking load, he said that Mr. Swinburne's hypothesis (on which the author bases his arguments, and which assumes that the self-induction of an armature coil is small, and, therefore, only a weak field is required to effect sparkless reversal) was not justified. The coefficient of self-induction of an armature section, as measured by a ballastic galvanometer placed in circuit with a coil wound close to a disconnected section, he found to be very considerable, and by passing various currents through the latter the variation of the coefficient with armature current had been ascertained. The difficulty of variable lead could, as was well known, he got over by using "commutating magnets" or "reversing pole pieces." Those shown in Mr. Swinburne's paper on "Armature Reactions" were quite inadequate as regards size, for in practice they had to be much more substantial.

Mr. Swinburne said Mr. Esson had not dwelt sufficiently on two of the chief advantages of having more than two poles. A four-pole drum armature had very simple end connections, could be perfectly ventilated, and was easily accessible for repair and inspection. The proper ventilation of large machines he considered to be of the first importance. The coupling up of multipolar armatures was, he said, to be condemned most strongly. Considering a large machine with its armature so coupled, and supposing the bearings to wear a little, he pointed out that a very small eccentricity would decrease the lower air gap and increase the upper gap by 1 per cent.; this means that in an armature having a loss of 2 per cent. the bottom half would do double work, thus involving great waste of power and heating. This objection, he believed, had not been urged before, but it was very serious in large machines. The armature conductors should, therefore, be in series, or connected partly in series and partly in parallel, as suggested by Fritsche.

Mr. Housman explained his method of analysing Foucault current and hysteresis losses in dynamo armatures by running them as separately-excited motors without load, and observing the volts and amperes required at different speeds.

Mr. A. T. Snell thought the term "volume of current" would be very useful as a name. His own experience as regards "volume" and diameter agreed with the formulæ given by the author. He did not agree with Mr. Esson that the output of an armature was independent of the number of poles, for he found that the output could be considerably increased by using four poles instead of two.

Mr. Miller remarked that in the case of dynamos for the transmission of power the design was influenced by the voltage of the machine, for there was a limit to the difference of potential that could safely and conveniently be used between commutator sections of ordinary construction. He also said that Mr. Esson had not even mentioned unipolar machines, presumably because he considered they were worthless. This, he thought, was a mistake. One of the chief faults usually attributed to them—viz., that there was a great fall of volts between no load and full load—did not exist if they were properly designed.

Mr. Crompton said the information contained in the paper would be very useful to engineers. Some speakers had implied that there was no gain in making multipolar machines. This, he thought, was not correct, for his firm had constructed large four-pole machines quite as efficient as the two-pole type, with an economy of 40 per cent. in material. In his opinion no machine lends itself so well to the production of high voltages as the multipolar type.

The discussion was adjourned to the 23rd inst.

THE MANUFACTURE OF SOAP.

By W. Lawrence Gadd, F.I.C., F.C.S.

(*Continued from page* 380.)

V.

The soap is drawn out of the boiling pan, from above the "nigre," through a pipe provided with a swivel joint, to admit of its being lowered by means of a crab and chain, and carrying at its upper or open end a shovel-like skimmer. The soap is then conveyed, down an inclined wooden shoot, to the "crutching" machine. This consists of two jacketed pans, kept hot by steam, connected together, and having in their centres vertical shafts carrying a number of horizontal arms, consisting of flat iron bars attached at one end, in an inclined position to the vertical shaft, and reaching nearly to the inner circumference of the pan. In the intervals between these arms, fixed bars extend from the pan side to the vertical shaft. The shafts and arms are rotated by toothed gearing, actuated by a small vertical engine, attached to the outside of one of the pans, which are used alternately, the rotating arms being thrown out of gear, and the flow of soap shut off from one crutcher while the other is being used. As soon as the soap begins to pour into the first crutcher, the arms are set in motion, and the desired amount of silicate or other solution, called "runnings," measured in. When French chalk or similar weighting material is used, it may be mixed with the runnings in a small pan fixed immediately above the crutching machine, and run from thence by a pipe leading into the crutcher. If necessary, colouring matter in solution, and perfume, are also added, and the revolving arms passing between the fixed bars thoroughly mix these and the runnings with the soap, so that, by the time the crutcher has received its full quantity of the latter, a uniformly smooth and homogeneous fluid is obtained. The flow of soap from the boiling pan is then directed into the other crutcher by closing one outlet in the shoot and opening the other, and the running and crutching are continued as before.

In this way the process is continuous, and the flow of soap need not be checked until the experienced eye of the attendant watching the stream at the point where it leaves the boiling pan, detects the first signs of the inferior nigre. The crutching pans are emptied after each mixing operation, by drawing a slide covering an outlet in the bottom, and the soap pours out into an inclined shoot, which conveys it into the frame room.

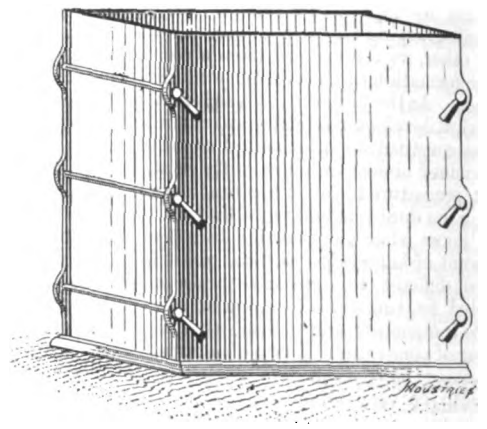


Fig. 4.

This is a large, airy and well-ventilated room, containing the receptacles in which the soap is cooled and solidified. These are sometimes made of wood, but more commonly, and indeed now almost universally, of cast-iron rectangular plates, which are fitted on a base plate and clamped together at each end to form an oblong box, open at the top, as shown in Fig. 4. These frames are placed in rows on the floor of the frame room, carefully aligned on each other to facilitate the subsequent cutting of the soap, and they are usually made tight at the bottom by stuffing twisted strips of paper into the groove in the bottom plate, in which the upright sides and ends of the frame stand. To prevent the soap from sticking to the iron plates, and so tearing when the frame is detached, the whole of the inside is white-washed with lime, and, it need hardly be stated, that the utmost cleanliness, not only in the frames, but in the shoots and all instruments which touch the soap, is absolutely necessary.

Suspended by iron rods above the rows of frames, are the inclined wooden shoots which carry the hot liquid soap from the crutching machine to the frames. These are merely wooden troughs, provided at intervals along the sides, or in the bottom board, with openings, through which the soap is delivered to any one or more frames in the row (see Figs. 5 and 6.) The openings, when cut in the bottom of the shoot, are usually circular, and are closed by wooden plugs provided with handles, and inserted from above; but this form of shoot is not so good as that which has the outlets in the sides, and which are closed by a flat board, sliding in a groove, on account of the resistance offered by the plugs and handles to the flow of soap, and their obstruction to the scraping down of the semi-solid portions which cool en route to the frames.

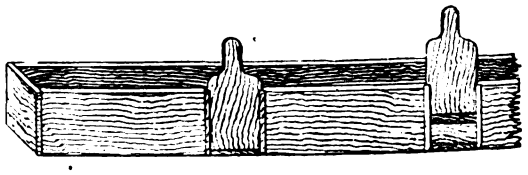

Fig. 5.

Fig. 6.

Commencing with those nearest to the crutching pans, or at the top end of the shoot, the frames are successively filled as full as is convenient, until all the soap is disposed of. Many kinds require also to be crutched again by hand while cooling, and before being left to set; and this is done by plunging a perforated plate of metal, attached at right angles to a long handle, and called a "crutch," into the soap, and working it up and down therein, the workman standing upon a square piece of board resting on the edges of two adjacent frames.

In some factories the scenting of the soap is effected at this stage, the essential oils being added gradually to the soap in the frames, and crutched in or mixed with it by the hand crutch, and, if properly and evenly crutched, this method is preferable to that of adding the perfumes in the hot crutching pan, as the loss by evaporation is,

Digitized by Google

in that case, considerable. When hand crutched, however, great care is necessary, or the essential oils will be found in patches or blots in the solidified soap. They should be added and well crutched, a little at a time, from a watering can or sprinkler.

As to the kind of perfume which is used for scenting household soaps, each manufacturer has his own ideas, both as to variety and quantity to be added, but the oils of citronella, spike lavender, lemongrass and sassafras, with nitro-benzene or "oil of mirbane," are perhaps the most commonly used.

On cooling down, the hot liquid soap placed in the frames contracts considerably in volume, and, if left alone, would not only sink and form a deep depression in the centre of the solidified block, but would probably be honeycombed or full of air spaces, and thus cause a great waste in cutting the soap into tablets and bars. To avoid this, the soap is hammered or beaten while in a plastic condition during the process of cooling. This operation, called "knocking down," is performed in the following manner:—A short time—depending entirely on the character of the soap—after the soap has become covered with a solid crust, the general surface is levelled, by running a knife round the inside edge of the frame, and cutting away the congealed soap irregularly crusted on the sides. A piece of hard wood, 4in. or 5in. square, and the same length as the inside width of the frame, is placed on the crust, close to the frame side, and gently hammered with a wooden mallet until the edge of the soap is depressed an inch or two. This is repeated all round the frame, causing the centre to bulge upwards, and care being taken that the surface crust of the soap is not cracked. After three or four hours, the piece of wood is placed crosswise on the arch formed, and the whole surface of the soap flattened to one level, and after an interval of about twelve hours, the mass is again vigorously hammered and knocked down still further.

After cooling for about forty-eight hours, the soap, though still hot to the touch, is sufficiently solid to be cut into slabs and bars, and it may be stated that as a rule, and within certain limits, the hotter the soap can be conveniently and without damage cut, the better will be the appearance and skin of the bars.

To cut the soap, the frame sides and ends are detached from each other and removed, leaving the solid block of soap standing upon the frame bottom. The whole surface is then scraped with an instrument called a scraper, shown in Fig. 8, to remove adhering limewash, and present a smooth surface, when the block is cut horizontally into slabs of about 2½in. thick. This was, at one time, done entirely by hand, and at small works still is so performed, the workman drawing a long loop of piano wire (see Fig. 7) through the soap, first marking the four corners of the block with a gauge consisting of a straight piece of flat wood, in which are fixed at intervals, corresponding with the thickness of the in-

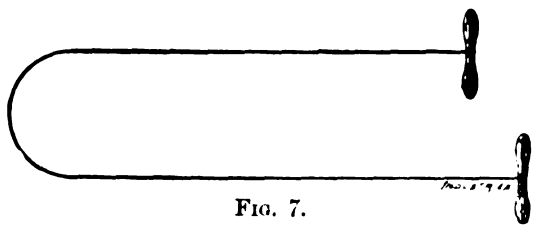

Fig. 7.

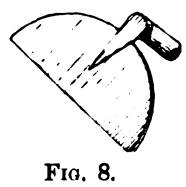

Fig. 8.

tended slab, a number of spikes or teeth. The cutting wire is passed round the block of soap, and is placed in position at the gauge marks on the rear corners by an assistant, while the cutter adjusts the wire to the front corners, and then, seizing the handles, draws them steadily towards him, forcing the wire through the soap, and cutting off a slab. The thin top and bottom slabs, along with the scrapings from the sides of the blocks, the ends of bars, and other scraps, are invariably returned to the soap pan, to be re-boiled.

The process of cutting the slabs by hand is, however, very tedious, and cannot be done where large quantities of soap have to be dealt with. Furthermore, the slabs are more evenly and equally cut, and there is less danger of spoiling them when machine cutting is resorted to.

A "slabbing" machine consists essentially of an upright wooden frame, rather wider than the soap blocks, which carries the tightly stretched horizontal cutting wires, and is mounted between light iron frames, running on wheels. The whole machine is propelled forward by a system of chain gearing and spur wheels, actuated by a winch handle. This machine is placed at the end of the first block of soap in the row, and propelled through the whole series, one after the other; the fixed wires, being forced through the soap blocks, cut them at one passage into twenty or thirty equal slabs. These are then loaded on to light trucks, or carried by hand, to the bar-cutting machines, which divide the slabs into the well-known 3lb. bars.

The bar-cutting machine consists of a wooden framework, on which is fulcrumed a swinging or hinged frame, containing a number of parallel vertical cutting wires. This frame is secured by a catch at the top of the machine, while the slab of soap is placed in position on its edge, and slightly slanted backwards against the wires. The catch is then released, and the hinged frame forced down, the parallel wires cutting through and dividing the slab. The frame is again raised, carrying with it the cut slab, which is delivered on to a board at the back of the machine, to be taken off by an attendant. The bars, removed from the cutting machine, are placed in open pile, crosswise upon each other, to cool and form a "skin" on the surface. Excessively watered cheap soaps are dried, and the skin produced, in stoves heated by steam.

(*To be continued.*)

NOTES ON OILS.

II.

The transformation of oleic acid into solid fatty acids is a problem which is of considerable practical interest, as its value for both soap and candle making is considerably less than either stearic or palmitic acids. The laboratory methods which are in use—viz., by the use of iodine and chlorine, or heating with solid potash—are too costly or too delicate to carry out on the large scale. A process which has been devised by Max Schmidt seems likely to put an end to this difficulty. An article in a French contemporary describes experiments made by another chemist on the process and the extent to which the transformation is carried. The following is an outline of the method employed:—Ten parts of oleic acid are mixed with one part of hydrochloric acid and zinc chloride, and the mixture is kept at a temperature of 180° C. until a portion taken out and heated with some more acid solidifies when cooled. The heating is then stopped, the product cooled, and repeatedly washed with water until every trace of zinc and of acid is removed. The purified fat is then distilled in a current of superheated steam or under diminished pressure. The distilled product is then subjected to hydraulic pressure in order to free it from the unaltered oleic acid. The solid residue should be white and have a crystalline appearance. The chemist who reports upon the process states that the metamorphosed fat, before distillation, has the following composition:—

	Parts per 100.
Liquid anhydride	8
Stearolactone	28
Oxystearic acid	17
Oleic acid	40
Saturated fatty acids	7

The composition of the product, however, varies with the temperature to which the mixture was originally heated. Thus, if the temperature mounts to 200° C., no trace of oxystearic acid is found, but the amount of liquid anhydride increases to 21 per cent., whilst the oleic acid falls to 24 per cent.

The recent meeting of the Scottish Mineral Oil Association, at which prices for paraffin and wax, to come into operation in August next, were fixed, shows that the development of the Russian petroleum trade is making itself felt upon this home industry, and as the American trade now possesses a very extensive fleet for the transmission of the American oil the Scottish trade has further increased competition to face. At Sunderland, the Anglo-American Oil Company have obtained permission of the River Wear Commissioners to carry underground pipes beneath the docks, in order to transmit burning oil from the landing stage to the new oil works to be constructed at Hendon. With regard to the new sources of petroleum mentioned in our last article, a highly promising report has been received of the oil from the Shirani country. The chemist to the Bengal Government certifies it as leaving 92·4 per cent. burning oil after distillation of specific gravity ·8 and flashing point 85° Fahr. This yield of burning oil is far higher than any previously obtained from natural petroleum, the highest yields of the Baku and American varieties being from 50 to 60 per cent. Some attention has been given since the opening of the year to the subject of the use of petroleum waste as a marine fuel, and reports are circulated to the effect that the Admiralty intend trying experiments with it. Mr. Nelson Boyd in a recent address referred to its use, both for this purpose and for locomotives. The advantages claimed for its use at sea by men-of-war are its increased power, 1 ton of oil occupying no more room than 1 ton of coal and giving power equal to 2½ tons to 3 tons of coal, facility of storage, and the fact of it giving no smoke to betray the vessel's whereabouts to the enemy. In connection with this, it is to be noted that the Rangoon Oil Refinery are preparing a new solid petroleum fuel by incorporating 3 per cent. of soap into the heated oil. The product is not easy to ignite, and burns slowly, with very little smoke and great heat.

During the distillation, the liquid anhydride is entirely decomposed, and the oxystearic acid is converted into oleic and iso-oleic acids. The following analysis shows the change in composition:—

Non-saponifiable portion	13·6
Oleic and iso-oleic acids	43·3
Stearolactone	31·0
Saturated fatty acids	12·1
	100·0

The distilled product, after being subjected to pressure, dried, and melted, forms a hard crystalline mass, which does not stain paper and is perfectly free from oleic acid. Its melting point is about 41–42° C., and its general composition is:—

Stearolactone	75·8
Iso-oleic acid	15·7
Saturated fatty acids	8·5
	100·0

This forms an excellent material for making candles. A. Guyot has examined the chemical reactions resulting in the production of the stearolactone, &c., but the results are not of technical interest.*

A memorial, signed by the principal French oil crushers and seed growers of the Département du Nord, has been presented to the French Minister of Agriculture, asking for special protection to their own industries in the new tariff.† They point out the greatly diminished production of oils in France, as shown by the quantities sold during the last forty years, and also that now four-fifths of the oil consumed in France is supplied from abroad. They ask for a duty to be fixed on oil seeds proportional to their richness in oil, and also for the duties on the oils themselves to be increased in like proportion. Moreover, for the protection of the colza industry, a duty should be put upon mineral oil imported.

A new patent has been taken out in France by H. Stein‡ for the use of silicic acid as a decoloriser for crude naphtha, mineral oils, animal and vegetable fats, paraffin, resins, and waxy substances. The silicic acid is packed in sugar refinery filters, and the molten fat or resin is then run on it. The acid is afterwards compressed, and may then be washed with benzine to recover all the oil or fat, and roasted, when it is ready again for use.

MERZ'S UNIVERSAL EXTRACTOR.

We recently illustrated the above apparatus for extracting fats and oils from waste products, and so recovering such bodies in a form in which they can be again utilised (see *Industries*, Vol. IX., page 163). The extractor has since been used for the recovery of grease from the waters of scouring mills, and has not only been found to be economical in its working, but also in this particular case, has furnished a residue which has proved to be an excellent wool manure of high nitrogen content. A further application of the extractor, which we commend to the notice of local authorities and others, is for the recovery of the oleaginous and fatty refuse from large eating-houses and clubs and other waste, which now finds its way to the destructors, as by this treatment a saleable grease and a highly nitrogenous manure can be obtained. The following table shows the results which have been obtained with the above apparatus in preparing seed cakes for cattle food:—

	Proteids in 100 Parts. Pressed Cake.	Extracted.
Rape seed	31·3	33·1
Linseed	29·5	33·2
Earthnut	41·3	44·4
Sesame	31·9	34·2

In which it will be seen that the yield of oil is greater and the nitrogen content of the cake correspondingly increased by its use. Messrs. Nölting & Co., of Dunster House, Mark Lane, London, E.C., are the agents for this extractor in Great Britain.

SOCIETY OF CHEMICAL INDUSTRY.

LONDON SECTION.

On the 20th inst. Mr. W. P. Rix read a paper on "Stoneware and Its Application to Chemical Apparatus," in which he gave a historical sketch of the progress made in the manufacture of stoneware vessels adapted to the requirements of chemical industries. The paper was illustrated by specimens of earthenware manufactured by Sir Henry Doulton & Co., of Lambeth, and by diagrams illustrating the different shapes of joints, &c., which had been devised to make air-tight and water-tight connections in pipes. The author discussed the chemical constitution of various glazes, and pointed out that, in vessels required to hold acid and alkaline liquors, special glazes were necessary. For chemical stoneware, glazes of the following composition had been found suitable:—

	I.	II.
Silica	61·81	65·05
Lime.....	13·44	13·68
Alumina	12·71	13·14
Alkalies	11·05	7·24
Iron oxide	·82	·89

After discussing the process of manufacture of joints of various descriptions, the author drew attention to Stanford's and Doulton's joints, in which asphalte was employed for securely cementing the two connections. Stoneware slabs for sectional acid tanks were also shown, and an acid force pump in which the valves were so arranged that, being in a separate piece, if out of order the pump could be repaired without removal.

In the discussion which followed, Mr. Howard and the Chairman (Mr. Tyrer) congratulated the author, and referred to the progress which the manufacturers had made in coping with the difficulties of the chemical engineer.

Dr. S. Rideal next read a paper, prepared jointly by himself and Mr. A. P. Trotter, on "Tanning by the Aid of Electricity," in which was given a description of a series of experiments undertaken with a view of ascertaining what is the precise nature of the hastening effect produced when a current of electricity is passed through an ordinary tanning liquor in which the hides are suspended. After pointing out that many patents exist for the hastening of the tanning process by the employment of mechanical methods, the authors showed that the application of electricity for this purpose could only be explained by either (1) an electrolytic action or (2) by dialysis or osmosis. After reviewing the processes in which electricity had been employed to produce this hastening effect, they described in detail the plant of Worms and Balé and of Groth, a description of which has already been given in our columns (see *Industries*, Vol. VIII., page 498). They pointed out that in the latter process, which they had specially studied, the hides were suspended on frames, and were not subjected to any churning action, as in the former apparatus. Details of experiments conducted to ascertain the variation of the resistance of the liquors, with temperature, percentage of tannin, and loss of voltage due to polarisation of the electrodes, were given in the paper. They showed that under the conditions investigated the electrolytic effect was inappreciable, as considerably less than 10 grms. of hydrogen could be evolved by the total current used in a complete tannage. The hastening effect was observed at night, after the motion and electric current had been switched off, thus showing that the rate of absorption was increased by the hides being put into a condition favourable to rapid absorption by the previous action of the current. Diagrams of the variation of the rate of absorption of tannin from the liquor during the same tannage when no motion was employed, when motion alone was used, and when the tanning was hastened by the passage of the electric current were also shown. The authors conclude from their experiments that, with the apparatus employed, the rate of absorption was approximately sixteen times faster than the ordinary process. Specimens of leather (sole and belting) were exhibited which had been tanned in less than twenty days. The authors also showed that the composition of the hides, as shown by their nitrogen content during the progress of the tannage, corresponded to the loss of tannin from the liquors, and drew attention to the physiological experiments of Ehrmann, Edison, and Lawrence and Harries, as bearing on the absorption of compounds by the skin.

In the discussion which followed, Mr. Hooper referred to the quality of the leather produced by the new process. Mr. Anderson drew attention to the difference between the electrical action upon the skin and upon muscular tissue, Mr. Swinburne pointed out that the electrical energy consumed, as it is so small, could only bring about a condensation of the tannin with the gelatine of the hide if no electrolysis took place, and Mr. Falkenstein, of the British Tanning Company, corroborated the statements of the authors as confirming certain experiments which he himself had been conducting on the rapidity of tanning when a current of electricity passes through the vat. Mr. Tyrer was glad to note so much progress had been made in the new process since the Society visited the experimental works two years ago, and looked upon the future of the process as being full of promise.

Notes.

PUBLIC WORKS AT ROUEN IN 1890.

The petroleum basin at Rouen is now completed. The timber dock is not yet ready for use, but the filling in of the surrounding spaces and levelling of the same was proceeded with during last year. The plan to extend the line of rails of the Western Railway Company to the wood and petroleum basins on the left bank of the river has been approved of, and will be immediately put into execution. Four covered sheds, covering an area of 130,000 square feet, are completed; also five hydraulic cranes on the left bank of the Seine. There are five others now being put up on the right bank, and there is likely to be a further development in the number of these cranes in the future. The Chamber of Commerce is about to obtain permission to acquire land on the right bank of the river as far as Croisset, to enable it to extend the port at any future time, when it may be desirable.

A NEW COTTON MILL IN INDIA.

The latest addition to the increasing number of cotton mills in India is the Peeroo Mahomed Manufacturing Company, Limited, the new mills of which company were opened last month. They are situated within a short distance of Mahaluxmi. The premises in which the mills are located is a double-storied building, which has been recently built. The spinning machinery has been supplied by Messrs. Dobson & Barlow, of Bolton, whilst the engines and boilers have been manufactured by Messrs. Daniel Adamson & Co., of Dukinfield, near Manchester. The engines, according to *Indian Engineering*, have been stated to be 1,500 horse-power, and capable of working 50,000 spindles—that is, nearly 17,000 more than the number the mill is furnished with at present. On the ground floor of the mill are situated the blowing-room and the card-room, whereas the first storey holds mules and reels, and the second one mules only.

THE FRANKFORT ELECTRICAL EXHIBITION.

Great preparations are going forward to make this Exhibition a success. We do not yet know how far English electrical engineers will patronise a German exhibition. It is purely a matter of business. There is a general feeling that Germans will not buy foreign goods if they can help it, so that there is little chance of export into Germany. We hope such ideas are without foundation, and that English firms will find it to their interest to exhibit with as much enterprise as they showed in 1881. We are glad to notice Dr. S. P. Thompson's name among the jury. Messrs. Haasentein & Vogler are going to publish an official journal during the Exhibition, and they have sent out a prospectus in rather curious English. Referring to the scope of the journal they state: "The contents of the paper shall be far from theoretical dryness on one side and amateur shallowness on the other, its get-up not to be rivalled; it will refer in its amusing part also to the *entertaining* sides of the Exhibition."

A REMEDY FOR POTATO DISEASE.

A report of experiments on potato disease by M. Petermann, Directeur de la Station Agronomique de l'Etat à Gembloux (Belgium), has been recently issued. M. Petermann, like M. Girard in France, made tests with sulphate of copper, but he also tried another remedy—viz., sulphate of iron. His experiments showed that the sulphate of copper dressing was effective, and, whilst it did not injuriously affect the weight of the crop, or the richness of the root in fecula, it most certainly reduced the percentage of unsound or diseased potatoes. M. Petermann used a stronger dressing than M. Girard, his formula being (per hectare): Sulphate of copper, 50 kilog.; lime, 25 kilog.; and water, 25 hectolitres. The test showed diseased roots amounting to only 7 per cent. on the total quantity raised, as against 30 per cent. of unsound tubers where the dressing was not used. The treatment with iron is very favourably spoken of, as it resulted in the diseased potatoes being lessened in quantity by 12 per cent. The iron mixture is composed as under:—Sulphate of iron, 50 kilog.; lime, 25 kilog.; and water, 25 hectolitres per hectare. It is simply the substitution of iron for the copper, and the cost of treatment, M. Petermann says, is consequently much less. He regards the experiments as of vast importance, and contemplates further inquiry into the subject.

PUBLIC WORKS IN ECUADOR.

A Consular report states that no advance whatever has been made on the Duran and Chimbo Railroad during the past year, but trains have been running regularly as far as Chimbo, and serve already to bring large supplies of potatoes, vegetables, eggs, and other farm produce to the Guayaquil market. The Congress of 1890 passed a law, embodying a contract proposed by a French syndicate, for the purchase of the present railway company (Compañia de Ferrocarril y Obras Publicas), and for the extension of the line to Riobamba; but the final conditions of this contract have not yet been carried out by the syndicate, although it is reported that negotiations are in progress to complete all the arrangements made. Two similar contracts were also approved by the Congress—viz., for the construction of the Central Railroad from Bahia to Quito, and for that of a cart road from the Pailon to Ibarra. Both of these projects are in the hands of English firms; but up to the present no definite steps have been taken towards carrying them out.

MANUFACTURE OF SALT IN CHINA.

In China, salt, which is a Government monopoly, is obtained by the evaporation of the water of the brine wells which abound in certain districts of Sz-chuen. The wells, states the *Engineering and Mining Journal*, are found about 175 miles from Chung-king, on the bank of an affluent of the Yang-tze River, near the flourishing city of Tzu-lin-tsin. The manufacture of salt, which has been carried on in China for a period of nearly two thousand years, is conducted somewhat as follows, according to a recent authority:—By means of a rude iron drill, holes 6in. diameter, and varying from a few score of feet to 5,000ft. or 6,000ft. in depth, are bored in the rock. The boring is sometimes continued for forty years before brine is reached, and is carried on from generation to generation. When brine is finally found it is drawn up by bullocks in long bamboo tubes by means of a rope working over a huge drum. In the vicinity of the salt wells, natural gas wells are also found, from which gas is supplied to evaporate the brine in large iron cauldrons, leaving the pure salt as a deposit. The product of salt in some districts is enormous. There are twenty-four gas wells and about a thousand brine wells now in operation, producing annually 200,000 tons of salt, valued at $5,000,000.

THE COTTON INDUSTRY.

The cotton industry at the present moment is going through a crisis owing to the recent considerable decline in values of American cotton. Prices of the raw material are lower now than for some time past, the fall from a few months ago being a large percentage. Compared with this time last year, the difference to-day between then and now is close upon 1¼d. per lb. Spinners some months ago bought very freely of cotton in expectation of values rising, but speculators have missed their mark, and are now saddled with a rather serious loss. The crop will be the largest on record. Moderate estimates of the ultimate yield are 8,400,000 bales to 8,500,000 bales. Reports are now gaining currency that the new crop will be a smaller one, but these statements are said to be unreliable, and made for "lifting" present rates. In addition to a great American crop, the Egyptian crop is a larger one than usual, and of fair average quality in the lower grades. Florida cotton is poor, and disappointing to spinners. Yarns for home use made from American cotton have for some weeks past been dragging. The output of the spindles has not been sold. The result is that order lists are lighter than for some time past; in fact, stocks are beginning to show themselves in first hands. If things do not soon take a turn, spinners will begin to agitate for organised short time for a month or so. Cloth for the great Eastern sections has been flat for quite a month past. Calcutta and Bombay shippers have done next to nothing in the way of purchasing. Shanghai merchants, too, have bought very sparingly. The nearer outlets have done, on the whole, fairly well, as has also the home trade. Altogether, however, the cloth section is languid, and the feeling is discouraging in most directions.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

6th April, 1891.

5852. Grass, A. B. ..... Corn or flour mills.
5854. Wrigley, T. ..... Cast metal worms or screws for conveyors and method of moulding the same.
5857. Wood, J. ..... Improvements in the construction of steam engines.
5862. Beck, W. A. ..... Apparatus for slipping ships' boats.
5863. McNaughton & Boswell Valves for hydraulic elevators.
5864. Carruthers & Stevens Fish joints for railways or tramways.
5875. Clark & Hodgson..... Collapsible tubes.
5876. Carter & Fraser ..... Appliance for measuring and delivering granular materials.
5877. Crabtree, T. ..... Combined reducing and stop valve.
5879. Davis, J. M. ..... Coupling link for chains and chain cables.
5888. Morris, Wilson, Strickland, & Lambert..... Construction of tubes.
5891. Lake, W. R. ..... Apparatus for the propulsion of ships or vessels (*Clark*).
5896. Stoddart, T. ..... Cut-off mechanism for steam engines
5897. Murrie, J. ..... Feed apparatus for steam boilers, &c.
5901. Braubach, E. A..... Construction of and appliances for furnaces.
5906. Hallier & Letellier ... Winding apparatus for hauling or raising and lowering objects.

7th April, 1891.

5923. Anderson & Pollock ... Sewing machines.
5924. Row & Brew ..... Apparatus for heating or evaporating liquids.
5931. Hardy & Hardy ..... Valve seats and acid-resisting valves and cocks.
5942. Allen, J. ..... Chain gear adjustment of cycles.
5944. Hudson, Rennie, & Graham ..... Apparatus for the consumption of smoke in the furnaces of boilers.
5946. Avery & Anson..... Fixed poise steel yards.
5950. Von Garn, F. P. ..... Coupling devices for railway carriages or trucks.
5971. Thompson, W. P. ..... Machines for producing type surfaces for letterpress printing (*Dodge*).
5979. Thompson, W. P. ..... Steam boilers and method of utilising the heated products therefrom (*Westphal*).
5992. D'Odiardi, F. E. S. ..... Pneumo-dynamometers.
6000. Redfern, G. F. ..... Quick-firing guns (*Ternström*).
6006. Mahony, F. W. ..... Stop motions for looms.

8th April, 1891.

6016. Nuttall, R. D. ..... Removable toothed gear or cog wheels.
6020. Savage, F. ..... Propulsion of boats.
6028. Walker, G. A. ..... Speed indicators for engines.
6038. Watmough, F. ..... Sight feed lubricators.
6039. Scholefield, R. ..... Apparatus for moulding and pressing bricks.
6046. Dont & Parent..... Stop mechanism for looms.
6053. Munns, W. H..... Steam boiler (*Heming*).
6073. Horn, W. W. ..... Automatic car brake (*Seawell & O'Hara*).

9th April, 1891.

6076. Griffiths & Beddoes ... The propulsion of navigable vessels, aëronautic apparatus, &c.
6080. Wilson, J. D..... ... Cupolas.
6081. Laidlaw, J..... Centrifugal machines.
6090. Bickerton, H. N. ..... Gas engines.
6092. Skelton, R. T. ..... Machine for stitching flat wire ropes.
6094. Lanchester, F. W. ..... Gas engines.
6097. Thompson, W. P. ..... Controlling and regulating the admission of steam in steam engines (*Jalsoriczky*).
6110. Stein, B. ..... Steam boilers.
6111. Barnes, W..... Feeding coal to furnaces.
6112. Langensiepen & Schroeter ..... Lubricator.
6124. Wyss, Ballurt, & Quentin..... Apparatus for cutting screw threads.

10th April, 1891.

6133. Tedesco, L..... Cocks or valves.
6143. Austin, H. K..... Axle guards for railway and other locomotives.
6148. Watt, J. ..... Steam boilers, evaporators, and the like.
6153. Thorn, R. ..... Metal moulding machine.
6154. Cheetham, F. ..... Band or rope attaching device for the carriages of mules.
6161. Crawford, F. H. ..... The driving of gas engines.
6166. Taite, Carlton, & Derlby ..... Speed indicators.
6175. Lake, W. R. ... . Feed-water heaters and purifiers (*McConnell*).
6183. Raworth, J. S. ..... Shaft couplings.
6184. Ibbotson, A. B..... Automatic couplings and coupling buffers for railway vehicles.
6189. Zwerintzeff, N. ..... Power loom.
6190. Harper, R. R. ..... Method of and apparatus connected with block signalling on railways.

11th April, 1891.

6200. Sibley & Honeychurch Fluid pressure motors.
6216. Houlden, H. W. ..... Fluid pressure motor.
6224. Rundquist, F. H. ..... Construction of railway and other wheels cast in iron or steel.
6230. Berthon, E. L. ..... Boat disengaging appliances.
6242. McKay, J. ..... Tube expanders.
6245. Newsome & Harrison ... Method of reversing the rotary motion of spindles employed in mules, spinning frames, and the like.

ELECTRICITY.

6th April, 1891.

5869. Scarlett, G. ..... Indicators for electric bells.
5903. Grimston, Viscount J. W. ..... An electro-pneumatic rock drill.
5912. Sandwell, W. D. ..... The transmission of electricity to portable cranes, &c.
5918. Harris & Power ..... Electric batteries.

7th April, 1891.

5947. Chapman, H. ..... Method of and means for renewing or repairing the filaments of incandescent lamps.
5953. Byron & George ..... Voltaic batteries.
5972. Sillery, W. ..... Electric storage batteries.
5995. D'Odiardi, F. E. S. ..... Liquid electrodes.
5996. D'Odiardi, F. E. S. ..... Magneto-voltaic and static electrodes.
6003. Reilly, J. C. ..... Terminals for cables of electrical conductors.
6007. Lancaster, E. W..... Handles or taps for electrical switches.

8th April, 1891.

6012. Lundberg, A. P. ..... Switches.
6029. Walenn & Timmis ..... Electro-depositing copper, brass, and bronze.
6048. North, G. ..... Electric power apparatus.
6072. Carpenter, C. E. ..... Electro-heating apparatus. (27th September, 1890.)

9th April, 1891.

6104. Timmis & Smith..... Dynamos and motors.
6125. Ritter, J. J. ..... Apparatus for soldering, boiling, and heating.

11th April, 1891.

6194. Kingdon, J. A. ..... Electromotors for alternating currents.
6232. Gwosdepp & Bungé ..... Microphones for telephonic circuits and the induction coils thereof.
6243. Patz & Grebner ..... Galvanic batteries.
6247. Johnson, J. Y. ..... Automatic regulating apparatus in galvanic batteries (*Gendron*).

CHEMISTRY.

7th April, 1891.

5983. Le Sueur, E. A. ..... Apparatus employed in electrolysis.
5984. Willcox, B. ..... Production of azo colouring matters (*Farbenfabriken vormals Friedrich Bayer & Co.*).
5999. Greenwood, J. ..... Manufacture or production of chlorine and sodium amalgam.

11th April, 1891.

6234. Imray, O..... Production of basic gallate of bismuth (*Farbwerke vormals, Meister, Lucius & Brüning*).

MISCELLANEOUS.

6th April, 1891.

5851. Sowerby & Casper ..... Casting metals.
5860. Pilling, M. J..... Water and other taps.
5871. Rothwell, W. G. ..... Apparatus for distributing on the water oil or other liquids by means of explosive rockets or projectiles.
5885. Pickup & Pickup ..... Miners' safety lamps.
5886. Leffler, C. J. L. ..... Material for the manufacture of cutting tools.
5907. Siemens, F..... Regenerative gas stoves.
5908. Dulier, E. E..... Method of and apparatus for destroying smoke.
5915. Fleuss, H. A..... Refrigerating machines.

7th April, 1891.

5933. Waterhouse & Blantern ..... Wire mattresses and their frames.
5935. Davis, E. C. J. ..... The casting of pipes, columns, girders, &c.
5943. Kaye, J. W. ..... Oil cans.
5949. Horne, G. W..... An improved lamp.
5970. Boult, A. J. ..... Railroad chairs (*Wells*).
5977. Robson, J. ..... Preservative coatings for iron or other structures.
5985. Reap, J. ..... Tool for cutting wood to mitre or other angles.
5986. Meixner, F. ..... Barrels for firearms.
6002. Edwards, E. ..... Iron heating pipes (*Marloy & Legat*).

8th April, 1891.

6019. Reading, T. ..... Metallic packing rings and springs.
6026. Reddaway, F..... The manufacture and treatment of woven driving belting.
6044. Brook, E..... Gas furnaces.
6051. Munns, W. H. ..... Stove for heating railway cars (*Harris*).
6067. Mannesmann & Mannesmann..... Railway rails and joints.
6070. Lake, W. R. ..... Signalling apparatus for use on ships or vessels (*Fiske*).

9th April, 1891.

6078. Rhodes, J. C. ..... Signalling on railways.
6084. Westwood & Jones ..... Tubes.
6101. Bradbury, Cryer, & Houghton ..... Automatic shuttle guard.
6128. Johnson, J. Y. ..... The manufacture of gunpowder (*The Dynamite Actiengesellschaft Nobel*).

10th April, 1891.

6134. Laing, J. ..... The distillation of mineral oils and apparatus therefor.
6142. Murray, T. R. ..... Pipe joints.
6152. Jones, G. ..... Fettling for puddling furnaces.

11th April, 1891.

6193. Taylor, J. ..... Belting for driving purposes.
6199. Austin, H. K..... Method of constructing axle boxes and bearings for use upon railway vehicles.
6215. Pitt, G. ..... System of joining by casting, either in stocks or sand, in the joints of elbows.
6219. Young, L. H. ..... Locking nuts used in fastening the fish plates on the rails of railroads.
6223. Ryan & Flynn ..... Automatic signalling of railway trains and appliances therefor.
6235. Lang & Wigham ..... A process for protecting iron and steel wire against corrosion.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1890.

3858. Fowler.
5429. Tattersall.
5553. Denby.
5572. Millington.
6307. Armstrong.
6439. White.
6661. Brophy.
6717. Freeth.

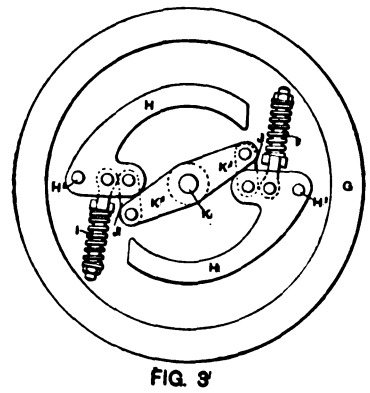
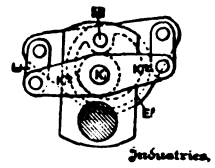
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.



Jacquard Looms.—*Thomis, Priestley, & Priestley, Bradford.*—This specification relates to improvements in the arrangement and construction of the uprights used in Jacquard double-lift open shed machines for operating the harness and healds. With uprights of the ordinary construction, when any require to be changed, the card cylinder is kept in contact with the respective cross wires until the ascending lifting grate has passed the descending hooks of the other legs of the respective uprights, when the card cylinder is allowed to recede and the uprights return to their normal vertical position and rest at the bottom upon the ordinary perforated guide board; but in this invention each pair of uprights is made separately, with a collar on each, and they are mounted independently of each other, and with their lower parts passing through a perforated plate. Between each pair of uprights is placed an additional upright with a hook at the top, and to the bottom of this centre upright is attached the harness or healds. The central upright carries a cross-bar, through holes in the ends of which the other uprights pass, and when either side upright is raised the centre upright is raised also, and retained by a stationary supporting bar until liberated by the card mechanism; the time of contact of the card cylinder is greatly reduced, and more time is obtained in which to allow it to change the pattern surface, thus the Jacquard loom may be run at a greater speed than would be possible with uprights constructed in the ordinary manner. Claims: In a Jacquard machine, the combination of the side and centre uprights as and for the purpose described.—No. 4787. March 27th, 1890. 8*d*.



Single-acting Steam Engines.—*N. Chandler, Hednesford, Staffordshire.*—An engine constructed on the principle of this invention is shown in the annexed illustrations, of which Fig. 1 is a sectional elevation and Fig. 2 a sectional elevation at right angles to Fig. 1 and taken through the valve chamber, Figs. 3 and 4 being enlarged details of same. Sliding in a suitable chamber on one side of the main cylinder A is the distributing valve B which regulates the supply and exhaust to the upper end of A and is actuated through suitable connecting rod from the eccentric B^1 on the main crank shaft C of the engine. Connected to the lower part of B is a sleeve valve B^2, which is so adjusted that as the piston of the engine nears the lower end of its stroke

FIG. 1

FIG. 2

it closes the exhaust port D sufficiently to ensure a compression of the exhaust steam in the cylinder. Sliding inside B is a piston valve E, balanced by means of a second piston F, which is actuated by means of a connecting rod. The latter passes through the hollow connecting rod of B, wherein suitable stuffing boxes are placed, from the eccentric E^1 also on C. This piston valve is for the purpose of closing the supply ports in B, so cutting off the supply of steam at any desired point in the piston's stroke, and is governed directly by means of a centrifugal governor carried by the fly-wheel G, and consisting of two weighted levers H (Fig. 3) pivoted at H^1, and which are held in the position shown, when the engine is running at its normal speed, by springs I. The movement of this governor is transmitted to the eccentric E^1 and so to E by means of links J, connecting the ends of H to a radial arm K^1 on the rod K, which rod passes through an axial hole in C. Other radial arms K^2 (Fig. 4) are formed on the other end of K which are connected by links L with projections on an eccentric E. This eccentric at a point within the bearing of its strap is journaled on a pin M fixed to an extension on one of the crank arms of C. In order to cause oil to be thrown to the top of the crank chamber a trough N is arranged within the crank chamber and is

FIG. 3

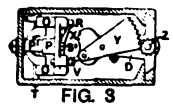


FIG. 4

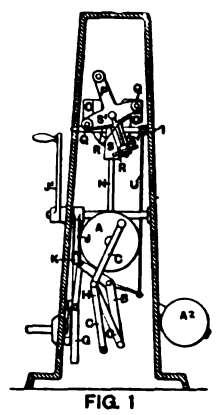
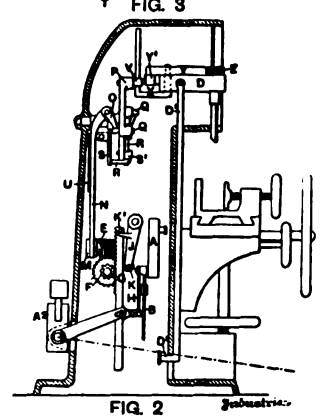


partly immersed in the oil and water therein. Fixed to one of the crank webs is a metal blade O, which, as the crank rotates, passes through the trough and forces the lubricant before it up the trough and out of a nozzle N^1 at the upper end thereof. Five claims are made.—No. 5076. April 1st, 1890. 8*d*.



Hydraulic Motors.—*E. Davies, London.*—A flexible bellows arrangement of waterproof material is used in lieu of a cylinder and piston, and is said to be particularly suitable for small power engines driven from ordinary water mains. The piston rod is secured at one end to the top of the cylindrical bellows, and at the other end embraces a crank pin. A special arrangement of plug valve is placed in the foundation at the base of each bellows, and is operated by a semi-circular tappet on the crank shaft. This arrangement of tappet enables the valve to be held open during the out-stroke of the engine, but shuts the same sharply at the desired point, and leaves the exhaust open during the back stroke. The plug of this valve contains two parallel passages, one for admission and the other for the exhaust. Claims: The motive power engine as described; the plug valve and means of operating same; the bellows arrangement in combination with the rest of the mechanism.—No. 4653. March 25th, 1890. 6*d*.

Pressure-reducing Valve.—*J. Scott & J. Thornton, both of Bristol.*—In a valve constructed according to this invention the valve box is provided with two valve seats. Steam at high pressure flows into a space between two valves of differential areas, lifting the upper and larger valve against the resistance of a spring adjustable from the exterior. The lower and smaller valve is loose and independent of the upper valve, and is held on its seat by the high-pressure steam, but a reversal may take place when there is no steam in the main boilers, to allow steam to pass from the winch boiler, back along the main steam pipe, through the small lower valve (which it lifts by acting upon the underside thereof), and thus into the passage which ordinarily constitutes the inlet for high-pressure steam, whence it is led by a special pipe to any desired point. Claims: A spring-loaded reducing valve with a return valve enclosed in the lower part of the same valve casing whereby steam may pass reversely through valve casing from low-pressure side in the absence of high-pressure steam from the opposite side; valves with oblique wings, causing slight rotation of valves when lifted.—No. 4328. March 20th, 1890. 6*d*.

Mortising Machines.—*J. Anderson, Newcastle-on-Tyne.*—This specification, which has been prepared in such a manner as to render its interpretation a matter of some difficulty, relates to an automatic arrangement for rotating the chisel of a mortising machine upon its axis, whilst at the same time it is in motion vertically. Almost the whole of the mechanism of a mortising machine is described, including a toggle and radius-bar arrangement for varying the stroke of the chisel, and an arrangement apparently intended to increase the depth of successive cuts from zero to a maximum, and on the completion of such a series to raise the chisel automatically in readiness to commence anew, but only the portion of the invention referred to in the first paragraph hereof appears in the provisional specification. Figs. 1, 2, and 3 illustrate a mortising machine in sectional front

FIG. 3

FIG. 1

FIG. 2

elevation, sectional side elevation, and sectional plan respectively, and in the views the chisel is carried by the vertically reciprocating slide D, and has at its upper end the spur pinion Z, which, with the segmental rack Y, which operates it, is also carried by D. The segmental rack is provided with a rearwardly extending tail or crank arm X, which extends upward also, so that at any point in the travel of the carriage it may be operated by the upper end of the arm P of a rocking lever, which is caused to oscillate by means of a plate S, and a somewhat complex arrangement of mechanism brought into operation thereby. It appears to be intended that the oscillation of the lever P causing a reversal of the chisel shall take place only on the completion of a series of cuts of increasing depth as aforesaid. There are three claims.—No. 3994. March 14th, 1890. 6*d*.

Chain Links.—*J. Scott, Liverpool.*—The inventor's object is to fix the studs of a stud link chain in position in the links after the links proper are constructed, and for this purpose the stud is divided in the middle of its length, each half being provided with a notched end adapted to fit the interior shape of the link, a wedge being driven in between the abutting ends of the half studs to keep them in position to form a strut across the link, the opposite ends of the wedge being riveted over into recesses formed at the junction of the halves of the stud. The operation may be performed with ease and rapidity by unskilled workmen. Claims: A stud link and the individual components thereof substantially as described.—No. 8040. May 23rd, 1890. 8*d*.

Cross Weaving Mechanism.—*J. Fairburn, Jun., Burnley.*—This is an arrangement for actuating the upper and lower needles used in cross-weaving, in which some or all of the warp threads do not lie parallel with eath other, but are crossed over as in "lenos," and are locked together by the weft shots. It is particularly applicable for securing the severed edges of fabrics woven in two or more breadths in the same loom and subsequently separated from each other by the severance of the weft. In this application of the apparatus four needles are preferably employed, two of which are fixed in a frame with their points projecting downwards, the other two being fixed to an oscillating piece with their points projecting upwards and being made to oscillate laterally to the right and left alternately with the motion of the needles above them immediately before the formation of the shed, and whilst the points of the upper needles are above those of the lower ones. The vertical movement of the upper needles to form the shed is effected by a band operated by the vibrating sley. The lower needles carrying the crossing threads are moved laterally by a cam operated by a ratchet wheel, which is actuated by a catch attached to the frame carrying the upper needles. The projections on the ratchet wheel may be varied in accordance with the design of the fabric to be woven. The slide frame carrying the upper needles when in motion brings a projection thereon against a tooth of the ratchet wheel to cause the latter to receive motion and to operate the lower oscillating needles as required. Claims: For securing parallel breadths a slide-piece

Digitized by Google

operated by projections to produce lateral movement at the points of the needles of the crossing threads.—No. 7550. May 15th, 1890. 8*d.*

MACHINE FOR DRILLING FALLERS.—*H. Haigh, R. Walker, & J. Mitchell, all of Keighley, Yorkshire.*—In the accompanying illustrations is shown a drilling machine for the above purpose, of which Fig. 1 is a plan, Fig. 2 a side elevation, and Fig. 3 a sectional front elevation. The bed A carries the upright and cross slides B and C, to hold the fallers, adjustable from handle D and hand-wheel D^1 respectively. A also carries the head E with drill spindle E^1, and a box F, in which is a disc F^1 with pin F^2 actuated by elliptical wheels G and H and gear wheels F^3, F^4, F^5, and F^6. As F^1 revolves it actuates a lever J^1, which,

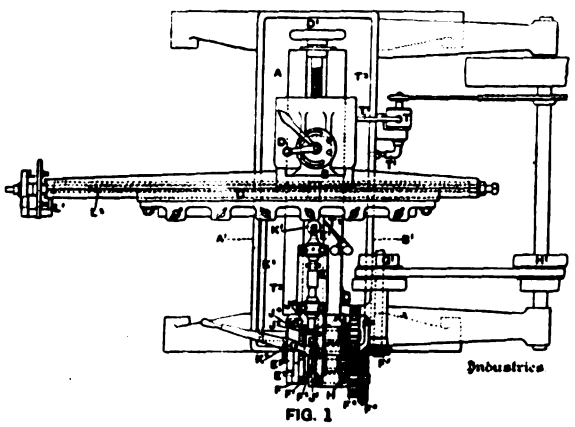


FIG. 1

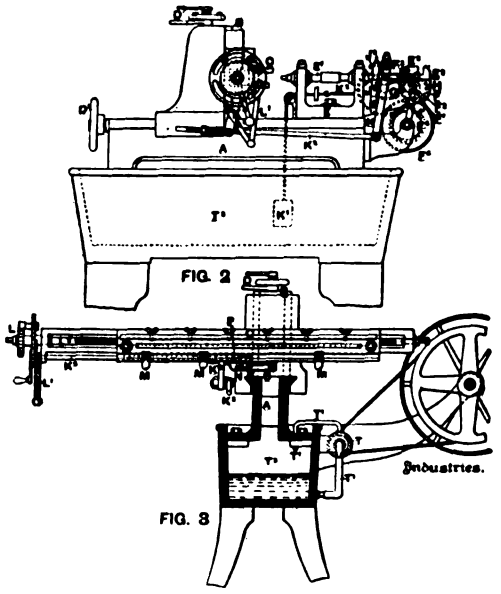
through a slide J^5 attached to E^1, feeds and withdraws the drill at intervals. After the drill has finished one operation, a stud J^2 upon the slide comes in contact with a spring catch J^3, pushing back the spring J^4 and releasing the slide bar E^2, which is kept in tension by the spring K. The slide bar E^2, on being released, operates a pivoted lever K^6, which in turn, by means of levers and rod K^3 and K^4, operates a horizontal rod K^5, giving motion, through levers L^1, to a ratchet and ratchet wheel L attached to one end of the cross slide, which operate a screwed rod L^2, moving the slide C and faller into position for the next hole to be drilled. The bar E^2 and the drill are brought into position for the next feed, by means of a weight K^1 connected to J by chain K^2 and an eccentric swivel E^3. Attached and adjustable upon C are dogs M fixed so that, when sufficient holes have been drilled in the faller, one of the dogs comes in contact with a spring catch N, depressing same and releasing a clutch P operated by lever R and spring S, thus throwing the horizontal rod K^5 out of gear, so preventing further movement of the slide; the



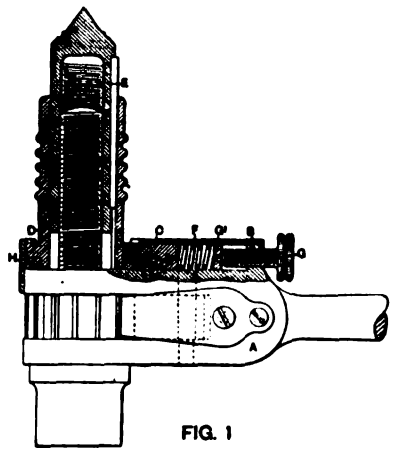


FIG. 3

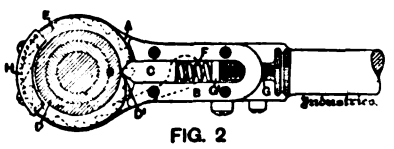
lever K^4, when not engaged with clutch P, is loose upon the rod K^5. A small pump T, operated from the driving shaft, is used for lubricating the drill, and which, by means of pipes T^1 and small nozzle T^2, propels a small jet of lubricant upon the faller; the liquid is placed within trough T^3. Six claims are made.—No. 5045. April 1st, 1890. 11*d.*

PNEUMATIC RAILWAYS.—*E. Locher, Zurich.*—In railways constructed according to this invention, hollow cylindrical carriages for goods and passengers travel in a cylindrical tube through which they are propelled by air pressure therein. The brake mechanism is adapted to act upon carrying and guide wheels, which are supported on bearings secured to the ends of the carriages and which travel upon longitudinal rails. Pressure is exerted between brake blocks and the peripheries of the wheels by a toggle and screw arrangement, and owing to the brake blocks being arranged on those portions of the peripheries of the wheels which are away from the rails, the operation of the brakes not only retards the rotation of the wheels, but presses the wheels against the rails and so produces a further braking action. The carriages make a tight joint with the interior of the tube by means of peripheral rings of metal, for example, arranged at short distances apart and almost touching the wall of the tube, by which arrangement of the rings annular air spaces are forced around the carriage—these spaces rendering equalisation of air pressure between the two ends of the carriage very difficult, if not impossible. Doors and the platforms for attendants are provided at the ends of the carriages. Compressed air may be employed to force the carriages through the tubes, or a partial vacuum may be created ahead of the train, which will then be propelled by atmospheric pressure acting at its rear. Claims: For pneumatic railways the hollow cylindrical carriages with carrying wheels, guiding wheels, and brake arrangements at its ends, as described; the combination with the foregoing of toggle lever brake mechanism; the arrangement of peripheral rings, as and for the purposes described.—No. 7826. May 20th, 1890. 11*d.*

SAW BENCH GUIDE AND FEED.—*F. R. Boultbee, London.*—This is an automatic feed and guide designed to obviate the dangerous manipulation on the bench of short and very narrow pieces of wood by hand. A reciprocating feed-block works in guides on the saw bench, and is reciprocated by a crank and connecting rod placed at the rear of the saw bench. A wooden fence and tilting cradle are attached to the feed-block, and are capable of being changed in accordance with the work required. The throw of the crank, and consequently the travel of the feed-block, may be varied at will, and the point of attachment of the connecting rod to the feed-block may be altered to adjust the range of the travel, and cause it to take place at distances from the saw which are in accordance with the size of the pieces being cut. The speed of the crank is regulated by the usual arrangement of cone pulleys. Claims: An automatic reciprocating device and guide as described; the combination of a changeable fence with the foregoing.—No. 7782. May 19th, 1890. 6*d.*

RATCHET BRACE.—*W. Kimber, Steventon, Berkshire.*—The inventor's aim is to obtain a self-acting feed. In the accompanying illustrations Fig. 1 is a part sectional elevation and Fig. 2 a part sectional plan of a ratchet brace with a female feed screw, and embracing the principle of this invention. On the shank A of the handle carrying the drill socket, rotating mechanism, and

FIG. 1



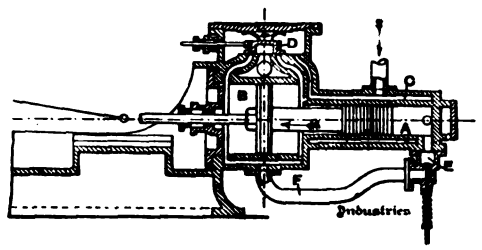


FIG. 2

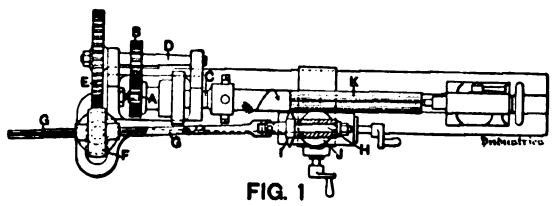
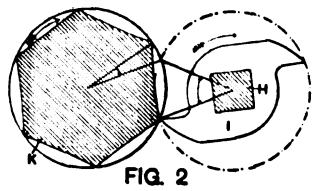
feed screw, is formed a box B, in which is fitted a sliding pawl C adapted to engage with one or more notches D^1 formed in the flange of a collar D mounted on the feed screw E. The sliding pawl C is pressed forward by a spiral spring F, the elasticity of which is capable of being adjusted by means of the milled-headed set screw G, threaded into the end of the box B, and acting on the spring F through the washer G^1. The collar D is connected to the feed screw E by means of a feather and feather-way, as illustrated in the accompanying illustration, and it is confined by means of a flanged plate H screwed, or otherwise fixed, to the top part of the shank A of the hand lever. The inventor also describes a brace with a male feed screw. Four claims are made, embracing the construction of self-feed ratchet braces as described, with modifications.—No. 12488. August 9th, 1890. 6*d.*



GAS ENGINE VALVE GEAR.—*O. V. Plauen & M. Hille, both of Dresden, Germany.*—This invention relates to the valve gear of engines driven by explosive mixtures, and the improvement consists in the combination with the admission valve for gas or vapour of a suitably balanced lever oscillated in one direction by the engine, and in the other direction by gravity, and through the medium whereof the operation of the admission valve is so controlled that the latter will be opened at every stroke of the slide valve or not, according as the engine runs at the ordinary or at an excessive speed. Opposite to the stem of the admission valve is arranged a reciprocating finger moving synchronously with the slide valve, and adjacent to this is placed the oscillating lever, which carries a movable pin controlled by a spring, the lever and the pin being so disposed that when the lever is in a certain position (the operative position) the pin will be lengthwise between the stem of the admission valve and the reciprocating finger. The pin has such a length that, under the said conditions, the finger on advancing will press the pin against the valve stem, and thus open the valve, the pin being pushed backwards again by this spring when the finger recedes. Sideward of the said lever there is an oscillating or reciprocating tappet, which, at every stroke of the slide valve, acts on the lever to oscillate the same so as to throw the pins out of line with the admission valve stem and the reciprocating finger; the lever is, however, balanced in such a manner that when the engine runs at the proper speed the lever, after having been swung out of its operative position, will return thereinto just in time to be again acted upon by the reciprocating finger at its next forward stroke. The admission valve is in this case opened at every stroke of the slide valve. But if the speed of the engine be too great the lever on oscillating backward will be too late for the pin to be engaged by the reciprocating finger; the admission valve will consequently then remain closed, and the cylinder will not receive any charge of explosive mixture. This skipping of charges continues until the engine has re-assumed its normal speed, whereupon the admission valve is opened again regularly. Claims: In combination with the admission valve of a gas or petroleum engine a valve gear of the type described. The details of this particular example are fully claimed.—No. 10642. July 9th, 1890. 8*d.*



COMBINED GAS AND COMPRESSED AIR ENGINES.—*J. C. Mewburn, London, Dr. R. Proell, Dresden, & E. Fischinger, Niedersedlitz, near Dresden, Germany.*—The present invention consists in combining a compressed air motor and a gas or explosive motor in such a manner that an exchange of heat takes place between the two motors—viz., that the excess of heat generated by the explosive motor serves to heat the compressed air while the excess cold created by the compressed air motor serves to cool the explosive motor. The accompanying illustration shows a sectional side elevation of one way in which the invention can be

carried out. A is the gas or explosive cylinder, and B the compressed air cylinder. The compressed air enters the jacket C of the gas cylinder at atmospheric temperature and takes up heat from the said jacket, whereby the compressed air becomes heated and the gas cylinder is cooled. From the jacket C the compressed air passes into the valve box and is distributed by a slide or other valve D to the two sides of the piston in the usual manner. When the two pistons have nearly finished their stroke in the direction of the arrow, the valve opens the front port to the compressed air, while the exhaust valve E of the gas cylinder opens simultaneously, and the exhaust gases from this cylinder, which are still of a high temperature, pass through the pipe F into the jacket of the compressed air cylinder, as well as into the compressed air cylinder, and simultaneously heat the cylinder itself and also the compressed air with which the gases mix, and the mixture is able to expand without undue reduction in temperature. When the compressed air is working on the return stroke in the back end of the cylinder heat is conveyed to it by the hot walls of the gas cylinder as well as by the hot piston and piston trunk. In two claims the inventors embrace the methods of combining a gas and compressed air motor substantially as and for the purpose set forth.—No. 7177. May 8th, 1890. 8*d.*

LATHE FOR TURNING ANGULAR SECTIONS.—*C. G. Dahlgren & G. H. Svensson, both of Göteborg, Sweden.*—A lathe for the above purpose is shown in plan in Fig. 1 in the annexed illustrations, Fig. 2 being an enlarged end view of the cutters. Geared by means of gear wheels A B with the live spindle C of the lathe is a counter shaft D, which shaft also carries a second gear wheel E, gearing with a spherical wheel F mounted by means of a feather on a shaft G. This shaft G is connected by means of a universal joint with the spindle H of the cutters I (Fig. 2) journaled on an ordinary slide rest J. The speed of the cutter relatively to that of the blank K to be operated upon may be altered by replacing the wheels A B or E F by similar wheels of different relative sizes, so that any number of facets may be cut on the blank K. Claims: (1) The combination of a lathe adapted to receive and revolve a blank, with a rotary cutting tool adapted to be revolved with a velocity the proportion of which to that of the blank is equal to the number of facets to be cut by said tool divided by the number of blades thereon for the purpose described; (2) the combination of a lathe adapted to receive

FIG. 1

FIG. 2

and revolve a blank with a rotary cutting tool having two equidistant cutting blades and adapted to be revolved with a velocity the proportion of which to that of the blank is equal to half the number of facets to be cut by said tool; (3) the combination of the live spindle C adapted to receive and revolve a blank, gear A B, shaft D, spur wheel E thereon, spherical wheel F gearing with said wheel E, shaft G keyed to said wheel F and movable back and forth therein, universal joint and shaft H with rotary cutting tool, said tool having equidistant blades and adjustable rest block J carrying said shaft, the whole substantially as set forth.—No. 824. January 7th, 1891. 6*d.*

FLEXIBLE SHAFTING.—*F. Y. Wolseley & P. H. Craven, both of London.*—Shafting constructed according to this invention is particularly applicable to comparatively small machines, but is also applicable to larger shafting revolving in fixed bearings when the parts of such shafting are required to be at an angle to each other. In one example a flexible guide sleeve is shown, within which rotates the flexible shaft, composed of a number of pieces more or less barrel-shaped, the radius of the barrel being approximately that of the smallest curvature in which it is intended that the shaft shall be worked. The ends of the barrel-shaped pieces are preferably convex, and have formed in them cylindrical holes parallel to their axis, the holes being so disposed that when the pieces are end to end the holes in one piece correspond with

Digitized by Google

those in the next piece. Cylindrical pins, somewhat smaller in diameter than the holes, are inserted therein, so that the opposite ends of each pin take into the holes in the ends of adjacent barrel-shaped pieces. Thus any required number of these pieces are caused to rotate together, and the pins being loose in the whole of the pieces, the latter may be placed at any angle to one another without interfering with their rotary motion. A piece of cord or the like may pass through central holes in the entire number of the pieces and may be secured to washers at each end of the shaft to prevent their separation. Lengths of rigid shafting placed at an angle to one another, and revolving in bearings, may be connected by loosely fitting pins in the manner above described. Claims: The flexible shafts as described, with loosely fitting driving pins and separate pieces connected by a flexible end or the like; connecting lengths of ordinary shafting as described.—No. 7632. May 16th, 1890. 8*d*.

ELECTRICITY.

ELECTRICITY METERS.—*A. Gay, Brighton, and R. Hammond, London.*—The invention relates to an apparatus for measuring and recording electric currents. In the annexed illustration Fig. 1 is an elevation of the recording mechanism, and Fig. 2 the measuring mechanism embraced by the invention. The drum

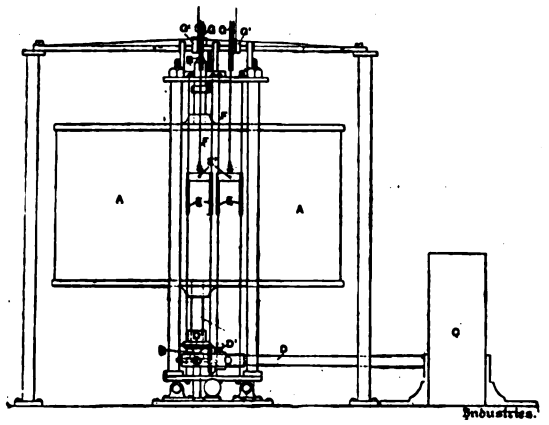


FIG. 1.

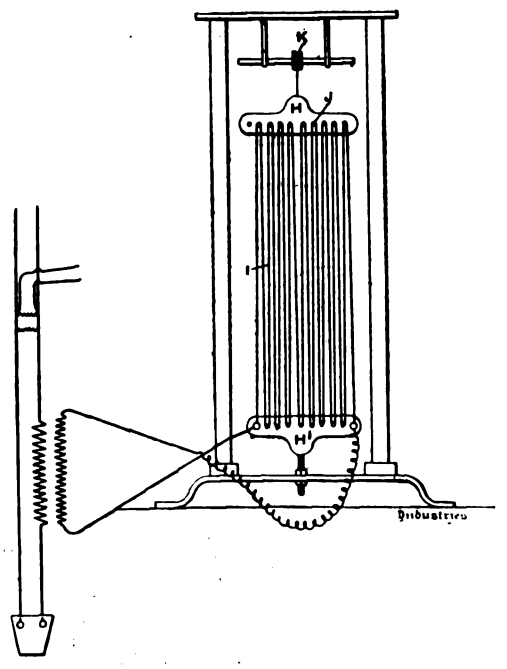
A, around which is placed the paper on which the record is to be made, is carried in cup jewels B in a suitable framework, and is driven continuously by means of a suitable clock-work in C, rod D, and bevel gearing D^1. Sliding in slides E are carriages E^1 carrying the marking pens, the points of which project against the periphery of A. The carriages E are supported and moved by cords F on pulleys C. On the shafts of these pulleys are smaller pulleys G^1, around which are wound cords connected to the measuring mechanism. Referring to Fig. 2, the measuring mechanism consists of two plates H H^1 connected together by means of a fine wire I passed around pegs J, and the ends of which are connected to the electric mains if the current is continuous. If, however, the current is alternating, the said ends



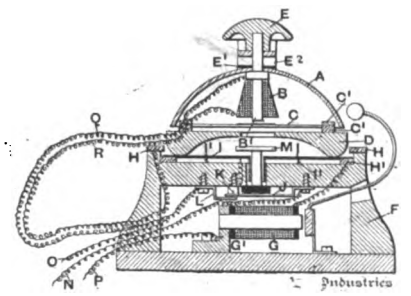


FIG. 2.

are connected in series with the secondary coil of a transformer. The plate H is connected to the cord wound on pulleys G^1 (Fig. 1) passing over roller K. It will thus be seen that any variation in the current will alter the distance between H and H^1, so raising or lowering E^1. In six claims the inventor embraces the apparatus as described.—No. 4992. March 31st, 1890. 11*d*.

ELECTRIC LAMP ILLUMINANTS.—*J. Clegg, London.*—The invention embraces a method of coating the illuminants with a metallic compound. For this purpose one of the following metallic solutions is used:—(1) Oxides of metals, or metals themselves dissolved in volatile solvents; (2) oxides of metals, or the metals themselves dissolved in a suitable solvent, and the resulting solution mixed with a volatile liquid. One of these solutions is placed in a suitable vessel in which the illuminant is suspended, which latter, after a vacuum has been created in the vessel, is electrically heated, which causes a deposition thereon of the oxide or oxides or metals. Claims: In the manufacture of light emitters or illuminants for electric lamps, the above-described treatment causing a deposit on them of metallic matter by electrically heating them to incandescence while they are suspended in a vessel from which air is excluded, above a volatile liquid such as alcohol, having dissolved or suspended in it a haloid or acid salt or an oxide of some one or more metals.—No. 694. January 14th, 1890. 6*d*.

DYNAMO ARMATURES.—*J. Nebel, Charlton.*—In place of winding drum armatures in two parallel circuits from brush to brush, in which arrangement a large sectional area of conductors is required, which, as radial depth is limited, must be obtained by increased width, reducing thus the number of conductors and of commutator segments, the inventor winds two, three, or more sets of convolutions side by side, each set having its series of commutator segments, thus reducing the sectional area required for each conductor, and proportionally increasing the number of commutator segments. The brushes touch simultaneously as many of the commutator segments as there are parallel windings. Claims: A drum armature having two or more separate conductors, or, as an alternative, two or more lengths of a continuous conductor wound a number of times round the armature, each convolution connected to a separate commutator segment, and each of the brushes covering simultaneously as many segments as there are conductors.—No. 4824. March 27th, 1890. 8*d*.

ELECTRO-TELEPHONIC APPARATUS.—*E. F. Furtado, London.*—The inventor's object is to simplify the construction and to reduce the first cost of apparatus of the above description. In the annexed illustration is shown a sectional elevation of a telephone constructed according to this invention for standing on a table. A is the gong of the call bell, fixed to the back of which is the telephone coil B, the pole B^1 of which is made adjustable towards or from the diaphragm C, held between two rings C^1 on the mouth-piece D, by means of nut E, flat spring E^1, and bar E^2. The stand F carrying the bell coil G and hammer G^1 has two metal rings H H^1 attached to the upper part thereof, between which rings is a movable plate I normally forced upwards by springs I^1. J is a metal contact piece normally in contact with a binding screw K, L is a second contact piece, and M a push button. The wiring of the instrument is as follows:—N is line wire, O wire from battery, P wire to earth and battery, Q and R

receiver wires. When the receiver is placed on the stand in the position shown in the illustration, a circuit is established from line through contact piece J, screw K, plate I, ring H^1, and bell coil to earth by means of wire P, so that on a person at the transmitting station pressing the button M the gong is sounded. When the person at the receiving station takes up the receiver the plate I rises and presses against the ring H, thereby switching off the bell circuit and establishing a circuit from line through J, K, I, H, wires Q R, to battery wire O. When the button M is pressed a current is sent from battery through J and L to line round bell coil at the station with which communication is desired to earth and battery sounding gong at that station. Claims: (1) In electro-telephonic apparatus the combination of a gong forming a case or cover for the telephone mechanism with a means of sounding the said gong, as described; (2) in electro-telephonic apparatus arranging the gong of the call bell in the manner shown for the purpose specified.—No. 5008. March 31st, 1890. 6*d*.

ELECTRICAL WELDING.—*H. Lemp, Lynn, Massachusetts, U.S.A.*—According to this invention, the work during the operation of welding, upsetting, or the like, and while heated, is moved by hand or mechanically past electrodes conveying currents thereto. In the present invention, instead of securing the stock to copper blocks sliding upon two other blocks, the stock itself is slid past suitable current-carrying contacts bearing on the stock, and which remain stationary. Independent mechanical jaws are provided for the purpose of holding the stock, so that it may be traversed and have end pressure applied thereto during the operation. Thus, the current-carrying arrangements are not used for the purpose of applying pressure to the work, and therefore need only be proportioned for current-carrying purposes, the advantage of this arrangement being that the wear and tear is upon parts which are easily and cheaply replaced, and not upon surfaces which, for electrical purposes, must be maintained in perfect condition. The conducting wires or electrodes bear upon the work and move laterally towards the same, being carried in a fixed support and pressed against the work by a spring. A cam plate is provided for the purpose of disengaging the contacts from the work. An arrangement of current-conveying contact, provided with a water jacket for cooling it, is described in conjunction with a hydraulic piston for forcing it against the work. Where it is desired to rotate the work in the operations of upsetting and subsequent forging, an arrangement of lathe is shown in which the head-stock and tail-stock are both insulated from the base. The current-applying arrangements are insulated, and are similar to those already described. Claims: Current-bearing electrodes mounted on a fixed support in combination with mechanical chucking and damping devices, which are longitudinally movable; the spring and cam plate for engaging and disengaging the electrodes; means for rotating the work in contact with the electrodes; the cooling arrangement for the contact, and hydraulic piston in combination therewith.—No. 20986. December 23rd, 1890. 8*d*.

CHEMISTRY.

TAR PRODUCTS AND FUEL.—*J. Bowing, Tilbury.*—Small coal, coke, lignite, or the like is introduced with a suitable amount of water into a vessel capable of withstanding sufficient steam pressure. On top of the small coal or other material is placed as much tar, shale oil, or other similar material as is necessary, together with the coal for the purpose of forming briquettes, and for the extraction of coal tar products. Good results are obtained by using about 250lb. of tar or shale oil to each ton of coal. The vessel when charged is closed, and steam from a boiler is passed into the top of the vessel and allowed to force its way gradually downwards towards an opening in the bottom controlled by a valve; thus the tar is heated and, together with the steam and a variety of tar products, is driven into the body of the mixture, coating the whole of the fuel particles. A large proportion of the water in the mixture together with steam and free earthy matter passes out at the bottom orifice, and shortly afterwards the water and steam flowing out at the bottom will be found to be carrying with them a considerable quantity of various tar products, which may be collected and used. A hot and substantially dry mixture may now be withdrawn from the vessel and compressed into briquettes or used as fuel in its uncompressed state. Claims: Effecting the mixture of coal, coke, or lignite or the like with tar shale oils, or similar substances, by treating the coal when wet and in the presence of tar, to the action of steam; the recovery of the products from tar and shale oils in the manner substantially as described.—No. 9199. June 13th, 1890. 6*d*.

MISCELLANEOUS.

ANTI-CORROSIVE AND ANTI-FOULING COMPOUNDS.—*M. E. Dejonge, Stapleton, Staten Island, U.S.A.*—The compounds for the above purpose are made of the following materials:—Colophony, paraffin, fusel oil, zinc dust, and talc or asbestos. Example: To 1lb. melted paraffin are added 4lb. to 6lb. finely screened zinc dust and about 1oz. to 2oz. of agatite (talc or asbestos), according to the stiffness of the pulp desired to be obtained. The well-stirred mixture is forced through a fine sieve while in a heated state, and is then ready for use. Three claims are made.—No. 19160. November 28th, 1890. 4*d*.

METHOD OF WELDING METALS.—*H. E. Fowler, Newhaven, Connecticut, U.S.A.*—The method embraced by this invention refers principally to lap welds for joining the ends of band saws, plates, and bars, and the manufacture of water pipes, boiler shells, and the like. The process consists of first forming holes in one of the parts to be united, so that when the parts are heated and welded by any convenient means a portion of the metal of the other part will be forced into said holes, so strengthening the joint. In modifications holes are formed in both the parts to be welded, and in some cases these holes are made to coincide and pins or rivets inserted. Seven claims are made, embracing the methods of making lap welds substantially as described.—No. 3854. March 11th, 1890. 8*d*.

NUT LOCK.—*J. P. Bayly, London.* (*R. Conway, Argentville, Missouri, U.S.A.*)—The invention consists in forming the screwed portion of the bolt with ordinary grooves, leaving a section of threaded portion between each groove. This bolt is passed through the fish-plate and rail in the usual manner and is screwed into a square nut sufficiently large for its corners to come in contact with the flanges of the rail, so preventing it turning. The face of this nut is cut away in such a manner that a projecting angular piece is left in one corner thereof. This projection is formed with a dovetailed groove projecting from the corner of the nut towards the centre thereof, so that when the nut is in place upon the bolt a suitable locking-piece engages in the dovetailed groove and a band projection upon this locking key enters one of the grooves upon the projecting end of the bolt and prevents it unscrewing. Three claims are made.—No. 7108. May 7th, 1890. 8*d*.

EARTHENWARE PIPES.—*T. Street, Kilburn.*—To ensure a tight joint between lengths of earthenware pipe the inventor forms a pair of raised rings at the spigot end of each length, the outermost ring of the pair being slightly bevelled, and the space between the two rings forms a recess extending almost completely round the circumference of the pipe, its continuity being interrupted by a raised connection joining the rings together and lying parallel with the axis of the pipe, this connection being termed a "key." Within the flange at the opposite end of the pipe a pair of internal rings are formed, which have a recess between them, and which are also connected by a "key," the arrangement being such that when the lengths of piping are in position the internal and external rings and keys and the interrupted annular spaces exactly overlie one another. Holes are provided in a part of the flange which must be uppermost when the pipes are laid, and through these holes cement is poured to fill the spaces above alluded to. A groove in the face of the pipe is provided for the reception of clay if considered necessary, the clay being put into the groove before the pipes are jointed. Claims: Particularly the keys, and the filling holes arranged in relation thereto, so as to ensure a flow of cement round the joint.—No. 4490. March 22nd, 1890. 6*d*.

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d*. *or fraction of* 10*d*. *Remittances exceeding one shilling must be made by Post Office Order.*

PELLATT'S GUMMING MACHINE.

CONSTRUCTED BY MESSRS. JOSEPH RICHMOND & CO., LIMITED, KIRBY STREET, LONDON, E.C.

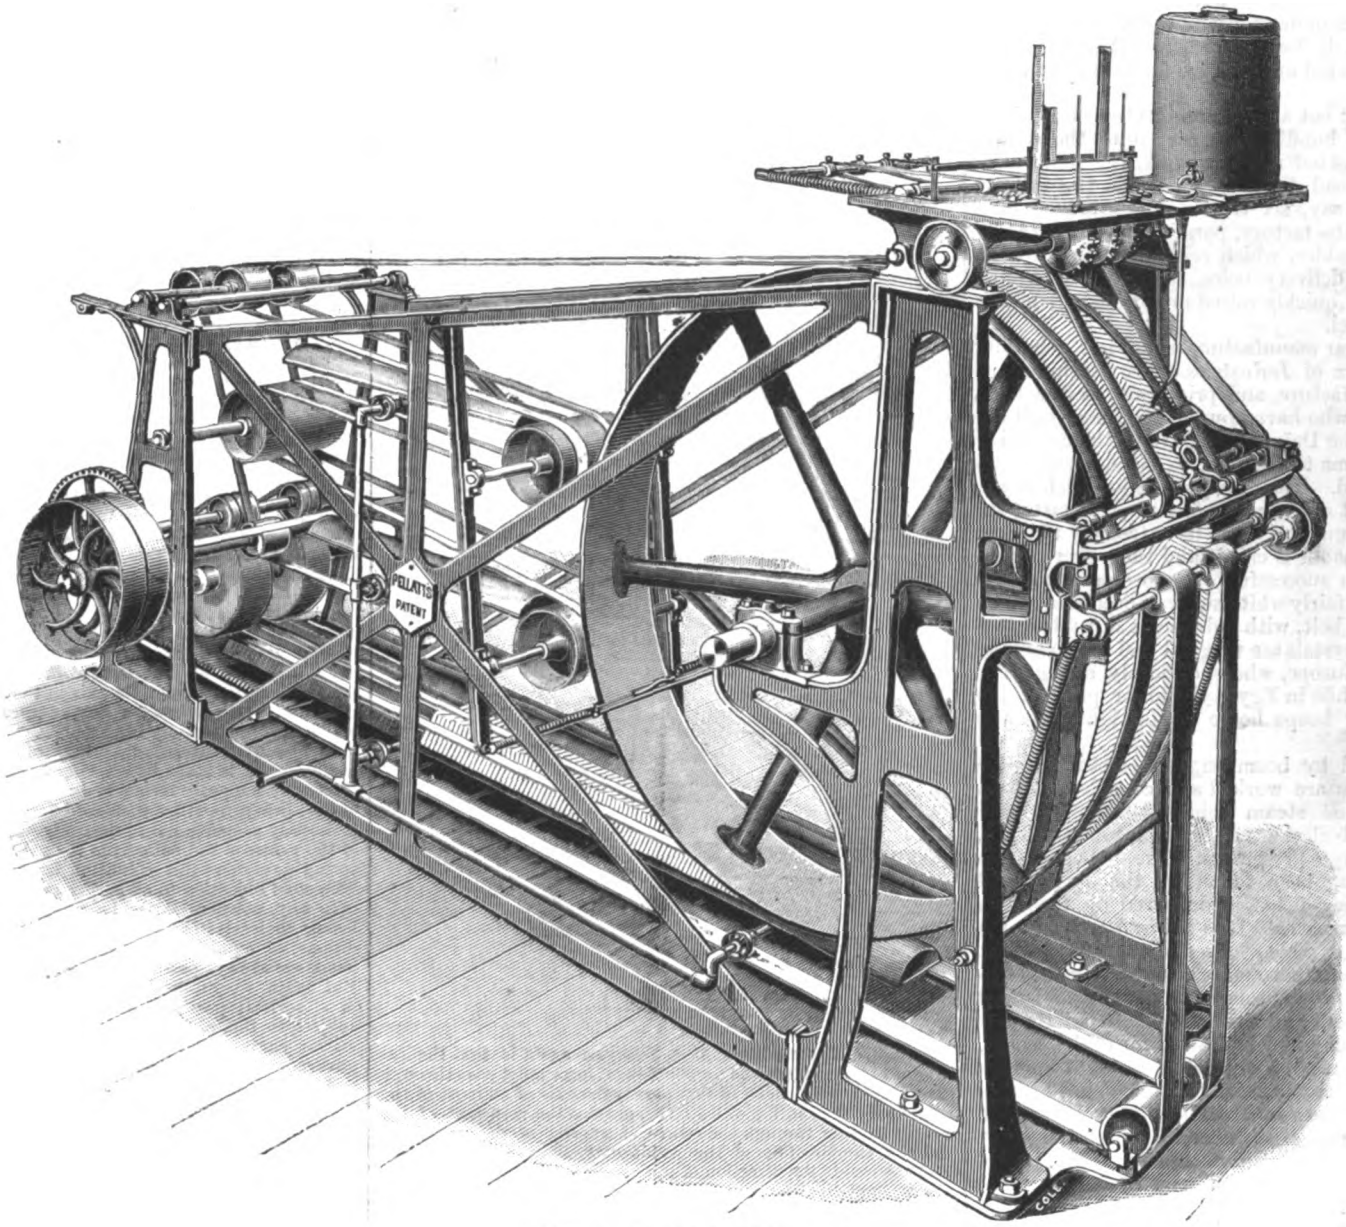

FIG. 1.—GENERAL VIEW.

IMPROVED PRINTERS' MACHINERY.

IN our issue of the 27th March we briefly noticed some of the principal exhibits of Messrs. Joseph Richmond & Co., Limited, of 30, Kirby Street, Hatton Garden, London, E.C., at the recent Printing, Stationery, and Kindred Trades Exhibition. We are now enabled to give illustrations of Pellatt's gumming machine and Gough's patent relief colour stamping press, which are shown in Fig. 1, above, and Fig. 2, on page 416, respectively. The former is for gumming envelopes, &c., and we are informed will fan out, gum, dry, and deliver envelope blanks at the rate of 20,000 per hour at an inclusive cost of one farthing per thousand. The machine occupies a space of 10ft. by 2ft. 6in., is self-contained, and requires very little power to drive it. It is simple, and, without requiring skilled labour, will operate on paper of varying thicknesses. The press shown in Fig. 2 is intended for stamping in relief bill and note paper heads, crests, &c., and also—by the half revolution of the ball lever—to wipe and colour the die. It is claimed that the results obtained by this machine are superior to copper plate or litho printing, and compare favourably for cost with these processes.

THE SUGAR INDUSTRY IN EGYPT.

By Mr. KILLINGWORTH HEDGES, M.INST.C.E.

IT will be quite another year before the new railway bridge, which is in course of construction over the Nile, at Boulak, will be finished, enabling passengers for the south to start from the Cairo Station, instead of having a long drive to the present terminus of the Upper Egypt Railway, which is at Boolak Dakroor. A seven hours' journey through a most fertile country, teeming with stock, and green with the first crop of "burseem," or clover, brings one to the head-quarters of the vast agricultural country which is known as the lands of the Daïra Sanieh. At first the reckless expenditure of capital by the ex-Khedive Ismail prevented any return being obtained either as interest or profit, but since the administration of the estates has been placed in the hands of a mixed commission of English and French, instead of being a burden, the cultivation of the land, and consequent employment of labour in the factories where the raw products are prepared for the European markets, has enabled not only the interest on the Daïra loan to be punctually paid, but has also rendered a reserve fund probable, which will no doubt be used for extending the factories.

The growth of the sugar cane and cotton plant are the principal industries on the lands of the Daïra Sanieh. These have an area of 327,000 acres, and are all under an irrigation system which of late years has been greatly developed, a special department having been formed on the Indian model, with English engineers for each district, who have been selected by Sir Colin Moncrieffe, the engineer-in-chief. Main canals run through the provinces, and from these branches are taken until the whole of the supply has been usefully distributed on the land. There is still a need for more reservoirs to pen up the water of the Nile when in flood, and a surveying party is now in Upper Egypt examining the proposed sites. Whether the Lake Moeris scheme of Mr. Cope Whitehouse, which has been so often advocated by this gentleman, will be included as suitable for one of the proposed reservoirs in Lower Egypt is uncertain. Although the flooding of the ancient lake would bring prosperity to the adjoining country, it would do nothing to help the irrigation of the country above; hence the delay in accepting Mr. Whitehouse's plan. On our way up country we had plenty of evidence showing that the late Egyptian Government did not neglect to try numerous methods of mechanical irrigation. There are screw pumps and centrifugal pumps by almost every known maker, lying idle by the score, and in most cases destined to remain so, while the pole and bucket of the "shadóof," worked by the Egyptian peasant or "fellah"—these contrivances raising water perhaps 30ft., by a series of lifts—are seen at work in every direction, until the borders of Nubia are approached, when the shadóof gives place to a clumsy water-wheel pump, called a "sakieh." A certain portion of land is irrigated by each pump, which is turned by oxen. The late Government found these wheel pumps a convenient means of taxation.

The Daïra lands are for the most part prepared for cultivation by the administration, who own over forty sets of steam ploughing tackle. The planting of the cane is done by the tenants, who are fellaheen, and who pay a rent of from £9 to £15 per acre. The whole of the crop is purchased by the Daïra by weight at a fixed price, so that all the tenant has to do is to cut the canes and bring them to the trucks. The price varies according to the quality and abundance of the crop; for this year, which is a very fair one, the pay is 7½d. per 100lb. of canes cut and delivered. The canes are planted in February and cut in January of the following year. For the next succeeding two years other light crops are sown —for instance, "burseem," or clover, may be grown the first, and the land allowed to lie fallow the second year, the canes being again planted the third year.

The sugar factories are thirteen in number, and may be classed as ten complete factories and three half-factories. They are named after the "teftisches," or

Digitized by Google

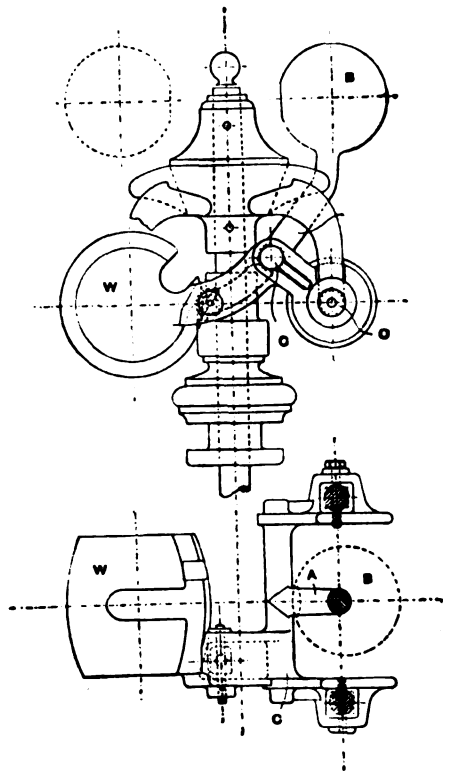
estates, which surround them, and stretch from Bibeh in the Lower to Motannah in Upper Egypt. The oldest have been established sixteen years, and nearly all those in Upper Egypt are connected by an agricultural railway about 500 kilometres in length, of standard gauge, which not only enables the canes to be brought to the factories, but also completes the connections with the railway which extends as far south as Assiout, but which is under construction to Girgeh, and will before long reach Assouan, where a short length of line already constructed enables the first cataract to be passed.

The canes are first cut and trimmed, then stacked on camels. The large bundles are secured to the camels by a single rope knotted round a stick, the removal of which allows the load to drop alongside the railway trucks. A train of, say, six trucks is shunted on to a raised platform at the factory, parallel with which is an endless revolving ladder, which raises the canes to the mill, the speed of delivery being regulated by a feed roller, which can be quickly raised or lowered by means of a large hand wheel.

The details of sugar manufacture would not generally interest the readers of *Industries*. The machinery is all of French manufacture, and principally comes from Messrs. Cail, Paris, who have now supplied nearly all the mills belonging to the Daïra Sanieh. With the exception of the addition of lime to the juice in the defecators, no chemical is employed. The only process in which power is not utilised is that of the scum presses; the latter are of simple screw design, and must be extremely tiresome to work; however, labour is cheap, and the power presses tried have not been successful. The process ends with the centrifugals. A fairly white sugar is produced, which is lifted by a canvas belt, with side pieces of rubber, to a floor above. The crystals are weighed and bagged ready to be exported to Europe, where, curiously enough, the demand is great, while in Egypt the lower price of the imported beet sugar keeps home production out of the market.

Power is supplied by beam engines erected in suitable positions; these are worked at a considerable back pressure, the exhaust steam being utilised for heating purposes. The boilers are after the locomotive type, only with extra large fire-grates. The "megass," or crushed cane, having been taken by the agricultural railway to the drying fields, is delivered by trucks in heaps close to the furnaces. It is fed by hand through a hinged furnace door, which leaves a space over a flat plate. The ashes, when thoroughly burnt, are pushed forward by a rake, and drop through the bars into a tunnel below, which runs under all the boilers. In all the factories a high brick chimney is erected for coal burning, but when megass is used a much less draught suffices, and an ordinary short sheet-iron chimney fixed above each boiler gives the best result. The facility with which this waste product megass is utilised has been the result of long practice, the evaporative efficiency of 2¼lb. of megass being equal to 1lb. of ordinary coal used under the same conditions.

The factories work night and day during the winter months, in shifts of six hours each, a European manager or deputy having to be on duty all the time. With this exception natives attend to everything, and work carefully and willingly, although the wages are on a scale which would be considered ridiculously low in Europe.



The larger factories manufacture their own gas for lighting purposes, but the results are not satisfactory. The electric lighting question is now receiving attention, and the writer has lately visited the factories, at the request of the authorities, for the purpose of reporting as to the cost of establishing and maintaining an installation of electric light, which shall not only illuminate the interiors of the buildings, but also the receiving yards and megass drying fields, the latter being the most important, as over 300 men are nightly employed outside each factory in drying and preparing the megass, and in transporting the canes to the mill.

STEAM ENGINE GOVERNORS.*

(*Continued from page* 392.)

Dr. Proell's governor, represented in Fig. 6, is another extremely interesting modification of the loaded Watt type of governor. In this case the arm D carrying the ball W is inverted and attached to the muff C, and it is guided by a second link attached to the spindle at A and connected to the arm D at B. The weight is thus constrained to move in a curve, the centre of which is at a point Z, and the effect is, therefore, somewhat similar to a Porter governor running at this considerably greater altitude. The graphic investigation of this governor may be followed out on the same lines as that adopted in connection with the Porter governor. The construction is indicated in the illustration, in which the lettering corresponds precisely with Fig. 1, but in this case the values given to the weights are purely arbitrary, and are not taken from an actual example. As designed by the inventor, the No. 3 governor running at a speed of only 160 revolutions has a velocity difference of 2 per cent. between the extreme positions, corresponding to a lift of the muff of about 2in., but the governor can be made still more sensitive if desired.

In the Buss governor, which is shown in Figs. 3, 4, and 5, a somewhat peculiar compound pendulum is employed, consisting of a bell-crank A, one end of which carries a ball B, and the other a cylindrical weight W. There is one pendulum of this description supported on each side of the rotating axis in such manner that the arm carrying the cylindrical weight W extends across the axis. Each pendulum is fitted with a stud C, which engages with and imparts movement to the muff. By a suitable choice of the weights of this pendulum, the system can be made absolutely isochronous within an angle of oscillation of about 20 degrees. Beyond this angle the pendulum is in unstable equilibrium in both

Figs. 3 and 4.

directions. The condition of equilibrium again is that the resultant of the weights and the centrifugal force must pass through the virtual centre which in this case is the axis of support of the pendulum; thus in Fig. 5 let F G represent the resultant of the weight passing through the centre of gravity of the pendulum, and F K the direction of the resultant centrifugal force: then F O represents the direction of the resultant of these forces and again completing the parallelogram F G H K, F K represents the centrifugal force. In the middle position this acts upon the weight B alone, and the speed may therefore be computed as before. In the other positions, the effect of the centrifugal force must be proportionately distributed over the weights B and W to determine the speed. In the number 00 size—which is here taken

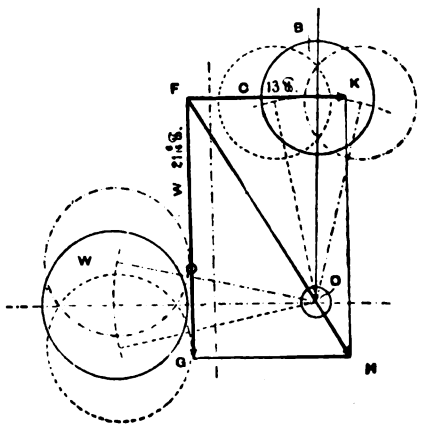


Fig. 5.

as an example—the total weight of each pendulum, together with one half of the muff, is 21·6/10lb., and the centrifugal force in the middle position is found to be 13lb., which corresponds to a speed of 188 revolutions per minute. Between the two extreme positions, the governor shows a variation of 2 per cent. only, and it could easily be made more sensitive if desired. The design of this governor is extremely compact, and the greatest degree of sensitiveness can be obtained with a very moderate speed. The latter is an important consideration, because not only does a high-speed governor require more driving power, but it is also subject to considerably more wear than another running at a slower speed.

If a governor is made extremely sensitive throughout its lift, there is considerable liability of over-running or "hunting," and this might be checked—whilst at the same time retaining the highest degree of sensitiveness—by making the governor extremely sensitive about its middle position, but less sensitive, and therefore more stable, on approaching the highest and lowest positions. This is one of the objects aimed at in the construction of the Four-Pendulum governor shown in Figs. 7, 8, and 9. In this governor there are four pendulums A, which are suspended in such manner that under the influence of their own weight alone they would fly apart until they had nearly reached their extreme outer position A, corresponding to the highest position of the governor. They are, however, held in the inner position by the weight of the muff W which is applied through the pivots of the pendulums. The latter are supported by short links C from the spindle at D, and the sliding weight, which is made in one piece with the muff, encloses the whole governor. A light spring E is inserted to add to the stability of the governor, and for adjusting the speed of the governor to a nicety. The small illustration shown on the left-hand side of Fig. 7 represents an arrangement for varying the speed of the governor whilst in operation. For this purpose the spindle is elongated and the muff is loaded by means of a spring S held down by a nut F, which is screwed on the spindle. By arresting the milled wheel G or F, the nut is caused to move on the spindle, the spring being consequently compressed or expanded, and the weight upon the muff varied accordingly. By the use of this extremely neat arrangement, the speed of the governor may be easily varied by about 50 revolutions per minute. This governor is so proportioned that it is almost isochronous about its middle positions, but a velocity difference of 8 per cent. is required to move it from the lowest to the highest position.

A governor constructed in such a manner that the height of the cone of revolution is constant in all positions of the balls could only be in equilibrium at the one particular speed which corresponds to this altitude, and the governor would therefore be absolutely isochronous. This result is obtained if the balls are guided so as to describe a parabola and supported in a direction normal to the parabola at every point. One possible method of obtaining this consists in hanging the balls from a flexible leaf spring wound upon a base curved to the evolute of a parabola. There are practical difficulties in the way of carrying out this idea, but a feasible approximation to these conditions is found in the Watt governor with crossed arms, if proportioned so that within the range of movement required the arc of a circle described by the balls coincides approximately with an arc of a parabola having its axis in the axis of revolution of the governor. In this way a governor can be easily constructed which is approximately isochronous.

In many centrifugal governors of the loaded class, the place of the weight is taken by a spring. The condition under which such governors can be made isochronous is that the resistance of the spring, together with the effect of the weight of the balls, is directly proportional to the centrifugal force or to the distance of the centre of the balls from the axis of rotation, and in some spring governors this condition is more or less nearly fulfilled. The chief objection to all spring governors is their liability to give way, not necessarily by breaking, but more frequently by losing their elasticity, thereby upsetting the whole of the conditions of equilibrium. Dead-weight governors, on the other hand, are always positive and not subject to any such changes. But again, weight governors can only be fixed with their axis in a vertical position, whilst many spring governors are not subject to this restriction, and are, therefore, also applicable on marine engines and in many other situations where a weighted governor could not be used.

A governor cannot, of course, prevent all variation of speed, because it is only brought into action after a change of speed has actually occurred, and the most it can do is to restrain the variations of speed within certain limits. For this purpose the governor must be as sensitive as possible, but the greatest degree of sensitiveness admissible in a governor is limited by other considerations. If, for example, a governor is made absolutely isochronous, it could only act by alternately closing and fully opening the valve, and manifestly this would be useless, because we require a governor to *adjust* the valve according to the power required. A governor which is too sensitive might in this way easily produce still greater variations of speed than a far less sensitive apparatus, and, indeed, there are instances in which engines labour under this defect. For most purposes the variation of speed of a governor between the highest and lowest positions should not be less than 2 per cent. of the mean speed, and, generally speaking, the sensitiveness of governors should approach as nearly as possible to this limit. This ideal cannot be conveniently attained with the Watt governor, nor yet easily with the simple "Porter" governor, but it is realised in the Proell, Buss, and other governors.

Another cause of unsteadiness in a very sensitive governor consists in the effect of the inertia of the moving parts, which will cause the governor to over-run or "hunt," and this difficulty is greatly enhanced with every increase of weight. The remedy for this defect consists in the application of what is known as a "cataract" or "dash-pot," consisting of a small cylinder containing a piston, the two ends of the cylinder being in communication by means of a passage, the size of which may be regulated by a small set-screw. The small piston rod is attached to the muff or other moving part of the governor, while the cylinder is connected to any fixed part. Such a dash-pot will offer a resistance to *sudden* variations of the position of the governor, whereas it will permit of *gradual* movements. It will therefore prevent over-running due to the inertia of the governor, without, however, affecting the sensitiveness of the governor, because it does not interfere with the condition of equilibrium, but merely retards any change of position. In cases where the highest degree of sensitiveness is required, such a check can scarcely be dispensed with. Dash-pots worked with oil or water have been introduced, but a simple air cataract, such as has been described, is preferable to these.

So far we have considered these governors merely in regard to their sensitiveness as speed indicators, without reference to the resistances which they are called upon to overcome. These resistances may be divided into two kinds—namely, the internal frictional resistance of the governor proper, and the resistances of the regulating mechanism. The effect of the former is almost insignificant in a well-designed governor. If the governor is combined with a good equilibrium throttle valve the total resistance to be overcome is also extremely small, and if the governor be only chosen sufficiently large, the resulting varia-

* Paper read before the Manchester Association of Engineers on the 11th ult., by Mr. C. F. Budenberg, M.Sc.

Digitized by Google

tion of speed will not greatly exceed those of the governor proper. On the other hand, the force required to move heavy valve gear is considerable, and in many cases amounts to several hundredweights. Such a resistance will, of course, very considerably affect the sensitiveness of the governor. It is, therefore, important to consider the action of governors with reference

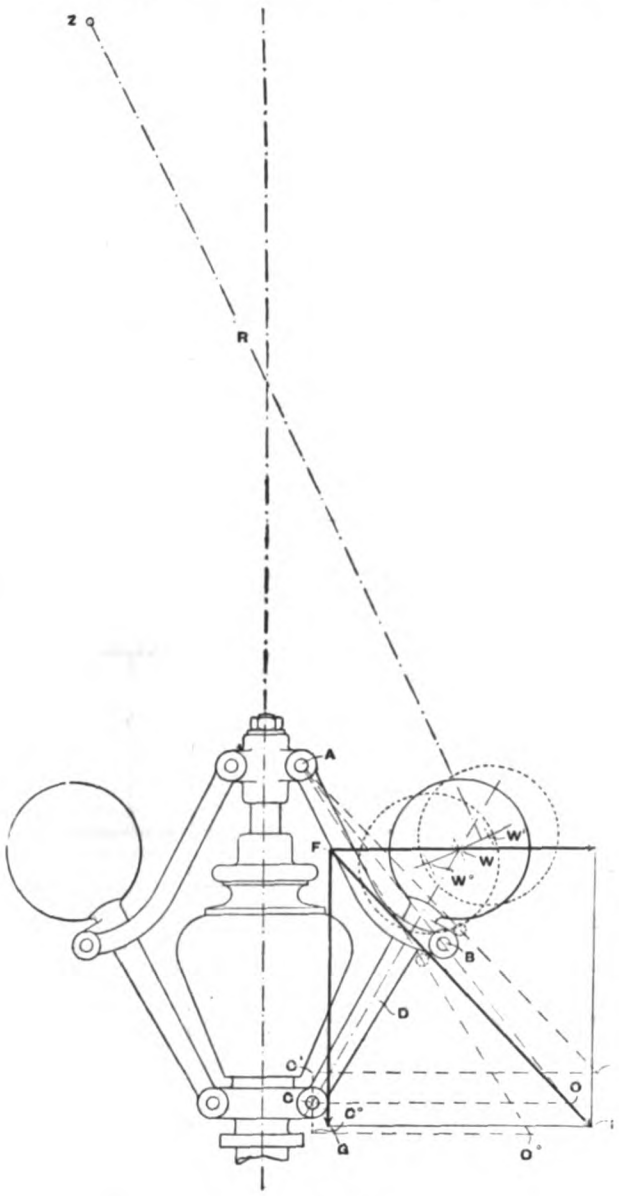

FIG. 6.

to the force which they are capable of developing with a certain variation of speed, and, given a certain maximum variation of speed, it becomes an important problem to determine the size of governor which will develop the required force within the given variation of speed. It is usual to denote as the "energy" of a governor the force in pounds which the governor is capable of developing with a variation in speed of 1 per cent. I prefer to call this the "force" or "powerfulness" of a governor, and would reserve the term "energy" to express the work which the governor would be capable of performing with a speed variation of 1 per cent., or one-half the powerfulness multiplied by the distance which the muff would move if set free with a variation in speed of 1 per cent. To determine the powerfulness it is only necessary to find out what additional weight would be needed on the muff to maintain equilibrium with an increase in speed of 1 per cent. The centrifugal force varies as the square of the speed, and therefore an increase in the speed of 1 per cent. signifies an increase in the centrifugal force of 2·01 per cent.

If in Fig. 1 we therefore produce F K to L, so that K L = 2·01 per cent. of F K, and draw a new parallelogram F L M, then continuing G H until it meets L M in N, M N will represent the powerfulness in pounds. In the present instance this would amount to nearly one pound. By determining the position of the balls if set free under the centrifugal force G N, we could arrive at the displacement, and this, multiplied by the powerfulness, would represent the energy of the governor. To give some idea of the powerfulness of governors as actually made, a list is appended showing the value of these in pounds for the different sizes of the Buss governor.

Powerfulness of Buss governor :—

No.....	000.	00.	0.	I.	II.	III.	IV.	V.
Lbs.....	1·2	1.4	1·6	2	3	4	6·4	12

Generally speaking, the powerfulness of a governor is proportional to the weight of its moving parts, and a loaded governor therefore has a decided advantage in this respect over another which is not weighted. In the Buss governor the weights are arranged in the most compact manner in proportion to its general dimensions, and this governor therefore has the advantage of a very great powerfulness, whilst occupying small space. In other words, in this governor the powerfulness attains its maximum in proportion to the space occupied, whilst in the Four-Pendulum governor the powerfulness is at its maximum in proportion to the weight, because the points of support of the

pendulums being in the weight attached to the muff, the whole of the weights help to give energy to the governor. In nearly all governors the powerfulness varies more or less in different positions of the muff, and to obtain the best results it is of importance that any such variation should correspond with the resistance required to be overcome. In the Buss and Four-Pendulum governors the powerfulness is not very variable, but the Watt and Porter governors produce a very variable degree of force in different positions, even at the angles ordinarily employed. In these governors the powerfulness is greatest in the lowest position, and is reduced as the muff rises, the difference in the force between the highest and lowest positions amounting in many cases to as much as from 12 per cent. to 16 per cent. In an ordinary throttle valve, however, the resistance offered increases as the valve closes, and this variation frequently amounts to 25 per cent. In these governors, therefore, the force developed is reduced as the resistance increases, and a proportionately greater increase of speed must therefore take place before the governor can close the valve. In the cross-arm governor the powerfulness is still more variable than in the Watt and Porter governors. In choosing a governor for any particular work, the resistance should first be determined, and, if the maximum allowable variation of speed is known, the required size of governor can be graphically determined by the methods indicated. Owing to the action of the resistance alternately in both directions, there always must be two limits of speed for each position within which the governor will not be affected. If the variation of speed of the engine in the course of one revolution exceeds these limits, the governor will move at each stroke of the engine. This is unnecessary, and an amount of friction sufficient to overcome this is therefore desirable.

(To be continued.)

THE NEW DALMARNOCK BRIDGE AT GLASGOW.

THE main road connecting the village of Rutherglen with the southern or Bridgeton division of Glasgow has hitherto been carried across the Clyde on timber structures. The first bridge spanning the river at this point was constructed in 1820–21, and was replaced in 1848 by a similar structure, also of timber. This, in its turn, having been found to require numerous repairs of late years, and being generally in an unsound condition from age, was condemned, and instructions were given to Messrs. Crouch & Hogg, of Glasgow, to submit designs to the Joint Bridge Committee for a structure, at once handsome in appearance and capable of accommodating the heavy traffic of this route. We give on our two-page supplement a general elevation of this bridge, shown in Fig. 3, and in Fig. 4 views of the pier and caisson, while Fig. 5 shows a half transverse section and part plan of the superstructure. Above and on page 413 we give views of the main girders (Fig. 1) and a part elevation of the parapet (Fig. 2). Numerous extensive manufacturing works are situated on both sides of the river, and the new bridge serves an important and rapidly growing district, in which the traffic is frequently of a very heavy nature, and the concentrated loads of considerable weight. A temporary structure having been completed, and the old timber bridge removed, in the spring of 1888, a commencement was made on the new one in July of the following year, the foundation stone being laid on October 11th, 1889. Owing to the presence of abandoned and inaccessible coal workings beneath the bed of the river, it was ultimately decided to adopt the girder type of bridge, although any further subsidence is considered highly improbable. The structure, the estimate for which is about £30,000, is, as now completed, one of the handsomest of those spanning the Clyde, and consists of five spans each 54ft. 8in. wide, the width between the parapets being 50ft., leaving a 32ft. roadway and two footpaths each 9ft. wide.

The bed of the Clyde at this point is composed of muddy clay and fine running sand overlying sandstone rock. In each case the foundation is formed on the rock, duly levelled and benched, the greatest depth attained being 56ft. below river bed. The piers were founded by means of caissons and compressed air. The caissons are rectangular in plan, with rounded ends, being 63ft. over all by 9ft. at the bottom, and 62ft. 3in. by 8ft. 3in. at the top. The working chamber is 8ft. high, an inner skin spaced 2ft. from the outer shell running around it. The skins are of ⅜in. plate, and are strongly braced together by double bracing of 3in. by ½in. bars, and frames of 6in. by 3in. by ½in. tees. The cutting edge is formed of steel plate 7in. by ½in. outside the iron skin, and by an internal 6in. by 4in. by ½in. steel tee bar running

Digitized by Google

around the caisson. The roof of the air chamber is strengthened by thirteen cross girders, 1ft. 6in. in depth, and running across the width of the caisson. Above the air chamber the skin is single and composed of ⅜in plate, being stiffened by three tiers of angle bracing spaced 11ft. 3in. apart.

Each caisson was furnished with two shafts of 3ft. internal diameter—one for the men, the other for spoil. The shafts were composed of ¼in. plate strengthened by 6in. by 3in. by ½in. tees running around them externally and spaced 4ft. 6in. apart. The joints of the inner and outer skins of the working chamber, as also those of the shafts, were kept tight by caulking. The permanent caissons extend to low-water level, above which temporary caissons were carried up above high-water. With the exception of the steel tee bar and plate forming the cutting edge, the caissons were constructed throughout of iron.

An interesting feature in connection with the work of excavation inside the caissons was the method adopted for dealing with the difficulty of getting the buckets expeditiously filled in a long narrow chamber 63ft. in length by only 5ft. effective width. A rail being fixed to each side of the inner skin, some 3ft. up from the cutting edge, a light trolly was constructed to run on this improvised line, which commanded the whole length of the caisson. The bucket, being lowered on to the trolly, could at once be pushed to any part of the caisson and returned with equal ease to the shaft when loaded. Whatever the state of the floor of the caisson might be, no interruption to the passage of the bucket could occur, as the caisson, of course, carried down with it this serviceable and ingenious device. It may here be noted that caissons and compressed air were employed in preference to open cylinders, owing to the existence of the old coal workings in the neighbourhood of the site already mentioned. Had such been met with open cylinders, flooding would have resulted, whereas by the employment of compressed air no inrush of water into the workings could occur. The air-locks were similar in construction, differing only in the details of winding arrangements in that for spoil and of air chamber in that for the passage of the workmen.

The air chamber was composed of $\frac{7}{16}$in. plates, strengthened externally by 6in. by 3in. by ½in. tee bars. The air chambers were lighted throughout by the electric light, and no difficulty was experienced in obtaining efficient native labour for the work under compressed air. With the exception of a mishap owing to both doors of an air-lock opening simultaneously, with accompanying escape of air and inrush of water into the air chamber, no accident occurred in founding the bridge, nor were any lives lost in connection with the caissons or piers.

The spaces between the two skins of the air chamber, and also the caisson itself, were filled at the commencement with enough Portland cement concrete to sink the caisson, additional quantities being added as required. Finally, on the rock being reached, and duly levelled and benched out, the air chambers were filled up with concrete well rammed, and subsequently grouted through the shafts, the remainder of the caissons being afterwards filled with concrete up to low water, and the masonry then commenced.

The piers, which are 62ft. 3in. over all, by 7ft. 6in. at cut-water level, and 53ft. by 6ft. above, are solid ashlar, and terminate in handsome moulded caps with fine red granite columns.

The abutments call for no special remark, nor has their construction entailed any work of exceptional difficulty. The wing walls are curved, and handsome granite columns and moulded capping stones are in keeping with the rest of the structure, and present a particularly pleasing appearance.

Passing on to the steel work of the superstructure, the spans, five in number, are made up of five parallel web girders, 3ft. 6in. in depth, with ⅜in. webs and 5½in. by 5½in. by $\frac{5}{16}$in. double angles at both top and bottom booms. The girders are spaced 10ft. 5in. apart from centre to centre, with the exception of the two outside girders, for which this dimension is reduced to 9ft. 2in. The four internal main girders are connected throughout their length by cross-girders, spaced 8ft. 4in. from centre to centre, having a depth of 1ft. 3in., and made up of a ⅜in. web plate and top and bottom flanges, each composed of two 4½in. by 4½in. by ⅝in. angles. Midway between these cross-girders are placed 6in. by 6in. by ½in. tees for carrying the buckle-plates of which the floor is made up, whilst plate bearers run parallel to the main girder, and are spaced equi-distantly between them. The plate bearers are made up of four 4in. by 4in. by ½in. angles, two forming the upper and two the lower flange, and a ⅜in. web, 1ft. 2⅜in. in depth, the upper angles being joggled to fit into the cross-girders. The flooring is made of ⅜in. buckled plate, 4ft. 7½in. by 4ft. 1½in., secured by ⅝in. rivets, 4in. pitch. The flooring under the pathway of each side of the bridge is, however, Lindsay's patent steel flooring, flushed with Portland cement concrete, and secured on either side to the main girder, on which it rests, by ⅞in. bolts. Rolled joists, 5in. by 4½in., by 23lb. per foot, and spaced 6ft. apart, connect the bottom flanges of the two outside main girders on both sides of the bridge, and form a support for the gas, water, and sewage pipes carried across the river by the bridge, beneath the roadway.

Handsome cast-iron facings are attached to the exteriors of the outside girders, divided into panels 3ft. square and of ½in. metal. The parapet, standing to a height of 3ft. 6¾in. above the level of the roadway, is also of cast iron, and consists of a series of columns 2¾in. in diameter, and spaced 9in. from centre to centre, terminating in square pedestals and connected by segmental arches, the whole forming a handsome design, and imparting a graceful and pleasing appearance to the structure. The roadway, 32ft. in width, has a rise in the centre of 4in., the buckle plates being covered with Portland cement concrete 9in. in thickness at the centre of the roadway, and 5in. in thickness at the sides. Above this a layer of sand from 1in. to ¼in. in depth is spread, on which 4in. granite cubes are built. The footpaths, 9ft. in width, have an inclination towards the roadway of 1in. in 4ft., and consist of 3in. machine-planed Arbroath pavement, backed by a layer of engine ashes bedded on clean lime mortar, grouted with cement, and protected from the roadway by a stout granite curb 12in. by 6in.

The main girders have a camber of 1in. at the centre. The iron employed in the construction of the caissons has a minimum ultimate tensile strength of 22 tons per square inch, with 8 per cent. elongation in a length of 8in. with the grain, whilst across the grain it is required to stand 18 tons per square inch, with 3 per cent. elongation in a length of 8in., and was manufactured by Messrs. Dorman, Long, & Co., Limited, of Middlesbrough.

The superstructure is of steel, having an ultimate tensile strength of 30 to 33 tons per square inch, with an elongation of at least 20 per cent. in a length of 8in. The usual bending tests were required—viz., that strips 1¼in. in width shall, when cold or after tempering, bend without fracture to a curve whose inner radius is equal to one and a half times the thickness of the specimen. The steel was rolled by Messrs. A. & J. Stewart & Clydesdale, Limited, at their Clydesdale Works at Mossend, and by Messrs. Goodwins, Jardine, & Co., Limited, at their works at Coatbridge.

THE NEW DALMARNOCK BRIDGE AT GLASGOW.

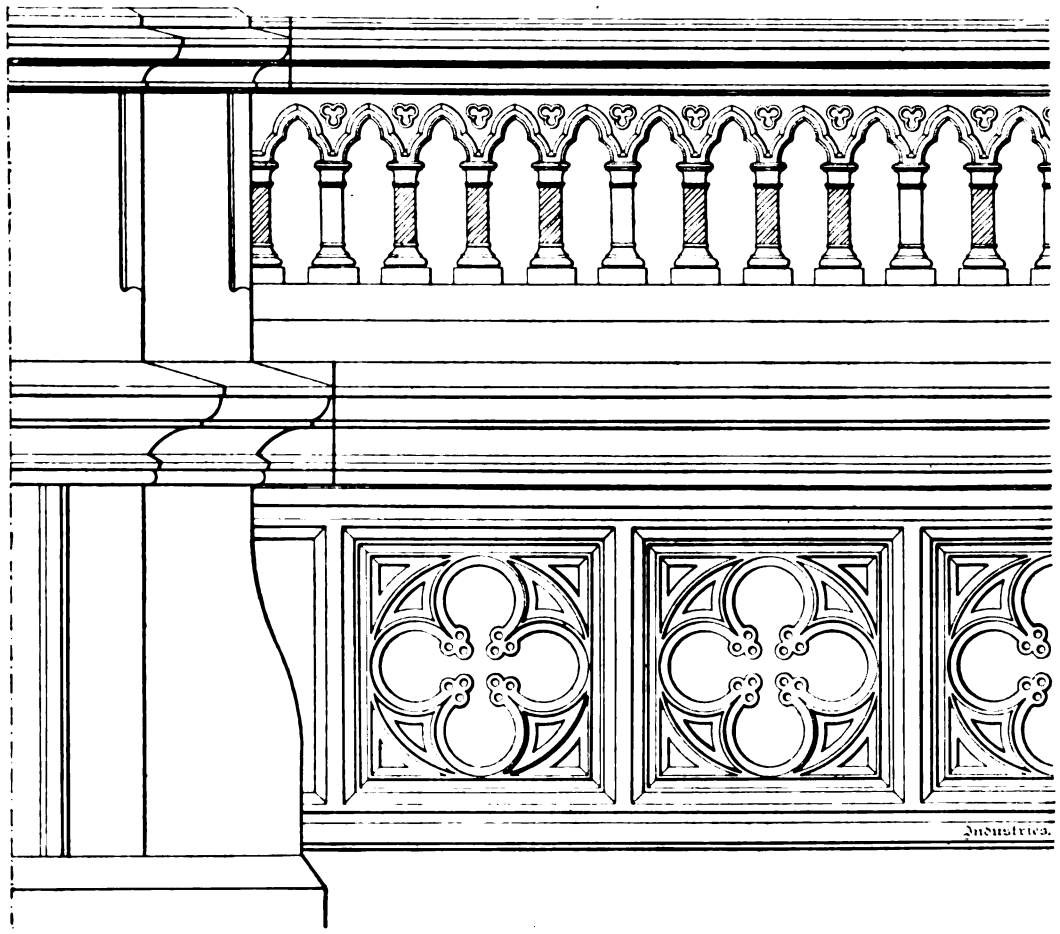

Fig. 2.—Part Elevation of Parapet.

The bolts and rivets throughout the structure are of Yorkshire iron, having an ultimate tensile strength of at least 24 tons per square inch.

The engineers are Messrs. Crouch & Hogg, of Hope Street, Glasgow, MM.Inst.C.E., and the contractor is Mr. A. H. Boyle, of Banknock, Bonnybridge, N.B.

The iron and steel work has been executed and erected by Messrs. Goodwins, Jardine, & Co., Limited, of Motherwell, and the ornamental castings supplied by Messrs. W. Macfarlane & Co., Saracen Foundry, Glasgow.

The structure was to be opened for traffic on Monday last, but the opening ceremony has been deferred until next week.

The courtesy of the engineers has enabled us to place the foregoing particulars before our readers, for which we are greatly indebted.

IRON AND STEEL WORKS IN CHINA.

From recent papers received from China we learn that some progress is being made in the erection of iron and steel works in that country. After much delay and discussion a site has been chosen on the northern slope of the Hanyang Hills, between the ridge and the Han River, opposite the city of Hankow, and thus close to the Yangtze, with which afterwards the works will be connected. It is understood that the works will comprise for the present two large blast furnaces of the Cleveland type, with all their appliances and machinery, and capable of producing about 100 tons of pig iron daily. There will also be a complete Bessemer plant, including two 5-ton converters, with cupolas, casting cranes, blowing engines, &c. The rolling mills are specially adapted for the production of rails; in fact, the chief object of the Chinese in designing these iron and steel works has been the supplying of material for their future railway system. They have, however, added a small Siemens-Martin steel plant, chiefly for the object of casting soft steel for ship plates and special metal for the Viceroy's small arms and gun factory. The malleable iron department will be tolerably complete, including some twenty puddling furnaces and a plate and bar mill, with all indispensable machinery. It is roughly estimated that the works will cover about forty acres. The most of the blast furnace plant has already been delivered, and the contract requires that the whole of the plant must be delivered in the first month of next year.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 28th April, 1891.

Iron.—The prices established by the Paris syndicate now rule the business of this market. These prices were for the past week 136s. 6d. per ton for bars and 144s. 6d. per ton for joists. This tariff has not been abated, except in one or two instances where the contract was of great importance, as in one case where an order for about 500 tons of joists was received at under 129s. per ton. The Government have signed a contract with the Mediterranean Iron and Shipbuilding Company La Seyne, for the building of the ironclad "Jaureguiberry," for which Messrs. Schneider, of Creusot, will furnish the armour plates. The state of the provincial markets is not so firm as that of Paris. In the Meurthe-et-Moselle district forge pig is quoted at from 42s. 6d. to 43s. 6d. per ton, and foundry pig at 54s. 6d., delivered at the works. The foundries of Pont-à-Mousson, which have large orders of pipes on hand for exportation, will be obliged to buy about 10,000 tons. This metal will most likely be brought into France temporarily from abroad. At Rosselange, in the Orne valley, much disaffection exists among the miners on account principally of the fines which they are obliged to pay if the percentage of stone exceeds a certain proportion of the iron ore got. In the Ardennes there have been no orders of any importance, and the market is very weak. Messrs. Warin & Son, of Sainte-Wast, Nord, are about to establish a sugar manufactory at Fins, the cost of which is estimated at about £18,000. The directors of the committee of the association of "The Iron Works of France," whose term of office had expired, have been re-elected, with Baron R. Reille as president.

Copper, Tin, Lead, and Zinc.—The increase of the stock of copper on the European market has caused this metal to depreciate in value here as elsewhere. The following are the latest prices quoted at Paris:—Best Chilian bars, £56 5s.; ordinary Chilian bars, £54 5s.; and best selected, £58 10s. the ton. The tin, lead, and zinc markets are dull, with a decided tendency to a falling off in prices.

The Manufacture of Submarine Cables in France.—The manufacture of submarine cables was not carried on in France until after 1889, when, the telephone lines having been handed over to the State, the General Telephone Company established workshops at Bezons-sur-Seine. In 1890, a cable was despatched from these shops and successfully laid between Martinique and Guadeloupe. Bezons having been found to be an inconvenient locality, the works have been transferred to Calais, and were inaugurated on the 18th inst. on the occasion of the shipment of a cable of 1,062 miles in length, weighing 2,367 tons, the first turned out of the new shops.

Launch.—The "Armand-Béhic," built at La Ciotat for the Compagnie des Messageries Maritimes, was launched on the 26th inst. She is fitted for the accommodation of 164 first, 179 second, and 112 third-class passengers. The length over all is 501ft. 7in., and width 49ft. 7in. The engines are triple-expansion of 700 h.p.

The French Navy.—The French Naval Estimates for 1892 are framed in view of the Mediterranean Squadron comprising three ironclad divisions, but the three small ironclads, the "Vauban," the "Bayard," and the "Duguesclin," are to be replaced by three larger vessels, while there is also to be a reserve squadron in two divisions, consisting of three small ironclads, three ironclad coasting vessels, three third-class cruisers, and three torpedo boats. In the Channel the ironclad squadron of the North will be composed of three men-of-war, an ironclad coasting vessel, a third-class cruiser, and four torpedo-boats, so that the French fleet in European waters will comprise, in 1892, eighteen ironclads, twenty-five cruisers, and torpedo boats.

Telephones in France.—It is probable that telephonic communication will shortly be established between Bordeaux and Paris, a distance of about 358 miles, as it is expected that the Chamber of Commerce and Municipality of Bordeaux will be willing to contribute towards advancing the requisite funds (about £2,600) to the French Government, which, under this condition, has consented to carry out the work and to undertake the management. Telephonic communication has also recently been established between Bordeaux and Pauillac, the port of Bordeaux, at a distance of about 25 miles.

BERLIN, 27th April, 1891.

German Coal and Iron Syndicates.—The yearly report of the Frankfort-on-Main Chamber of Commerce contains some important information as to the working of these syndicates. Various syndicates and conventions were formed in order to limit the production of pig iron. Working agreements were entered into between the coal owners, and a coke syndicate was formed, which absorbed the total production of the Lower Rhenish and Westphalian mines. Such unions have an important effect by making the production proportional to the consumption, and thereby regulating the prices. Notwithstanding the long and severe winter, the closing of river traffic, and the difficulties of transport on the railways, only a gradual and moderate recovery of prices has taken place. Though the unions make it their chief aim to maintain prices, these must be ultimately regulated by the general state of business and the demand of the public. Considerably higher prices have been arranged by the coke manufacturers for the summer contracts of the present year. This increase seems to be due to the efforts of the united coke selling conventions to maintain prices rather than to a real increase in the demand. The abnormally high prices of raw materials has a most prejudicial effect on German trade, and the improved state of German industries is counteracted by the increased cost of production, which prevents their competing with the other markets of the world.

VIENNA, 27th April, 1891.

The Iron Market.—The condition of the iron market has remained unaltered during the past week, and trade is still sluggish. The syndicates have maintained prices, but have not been able to impart any activity to the market. The large orders which have been expected have not yet been placed, but will no doubt arrive before long. The stagnation in the iron market will then be at an end. The negotiations with Germany are drawing to a close, and the Austrian tariff on iron would thus be reduced from 1s. 7d. to 1s. 2d. Mr. Wittgenstein is at present in Berlin for the purpose of making an agreement with the German works.

Austrian Exhibits at the Frankfort Electrical Exhibition.—The Electrical Exhibition at Frankfort will be the most important exhibition of electrical industry since the Vienna Exhibition of the year 1883. The progress of electrical discovery made since that year will be brought into notice, and the arrangement of the Exhibition is sure to be well considered and carried out under the able superintendence of the former director of the Berlin General Electricity Company. The progress made in the various works is very great, and the firms will no doubt do their best to be well represented in the competition. The installation for the distribution of power, which is being erected by the Oërlikon Company, is remarkable for the high tension of the current and for the distance to which the power is to be transmitted. Austrian firms generally are engaged in producing new machinery for the Exhibition. Messrs. Ganz & Co. are constructing an electrical railway on which the speed of the trains will be 28 miles an hour. Models and drawings are to be shown at the Exhibition. Messrs. Siemens & Halske, and Messrs. Kremenetzky, and other well-known firms will be represented. Mr. Kareis, Mr. Kohn, and Professor Schlenk have been chosen to represent Austria on the Exhibition Committee.

Explosion at an Ironworks.—A serious fatal explosion occurred to-day at Baron Rothschild's ironworks near Witnervitz, Moravia. The manager and six workmen were killed and many others injured. The disaster was caused by the bursting of a steam pipe.

BRUSSELS, 28th April, 1891.

Electric Lighting at Brussels.—Many private houses have been lighted electrically by means of Buffet batteries. The Belgian and Parisian Bank is trying to form a company for the purpose of working this system of lighting. Some opposition has, however, already been made to the scheme.—The contract for the poles required for the electric lighting of the Grande Place in Brussels, which had been opened to competition, has not yet been awarded, as the permanent commission has not approved the decision of the committee, who had decided on their use. The lighting of the Grande Place has been under consideration for two years past, and would be an interesting application of electric lighting. It is scarcely likely to be carried out under present conditions.—Some large installations have recently been erected by M. Dulait, of Charleroi, who is the head of the largest firm of electrical engineers in Belgium. In addition to various schemes carried out in Belgium, M. Dulait has numerous orders from France, and intends to establish an important agency in that country. The electrical and hydraulic works of M. Dulait have been largely extended, and the firm is engaged in the manufacture of carbons and insulators. Some of the staff are employed at the Charleroi central station, which is in itself a large business. The dynamos made by the firm have a good reputation in the industrial world. The electric lighting of the house of the Count of Flanders on the Julien system has been very successful. The rigidity of the plates is an important factor in keeping these accumulators in good order, and maintaining their reputation.—The Tudor system is also highly spoken of, and the company which supplies these batteries guarantees their successful working. There is an excellent installation at the brewery belonging to M. Willemans-Ceupens, and the Metropolitan Café is lighted by 400 incandescent lamps, which have a very pretty effect.

DÜSSELDORF, 28th April, 1891.

The Iron and Steel Market.—The condition of the iron and steel market, already a difficult one, has been made much more difficult by the renewal of the strike among the coal miners. It is reported that certain larger works, among which are the Rhenish Steel Works, the Phœnix Works, the Duisberg Works, and the Bothumer Works, have already stopped a part of their work in consequence of a want of coal. If the strike of the coal miners increases, a total stoppage of the Rhenish-Westphalian iron trade will result, since this industry, owing to competition, will not admit of higher prices being paid for coal. The price of puddled pig iron has already advanced, but for other sorts prices remain unchanged. Orders for 8,250 tons of steel rails and about 7,000 tons of iron sleepers, as well as the necessary bolts, have been placed by the State railway management at Cologne. The number of blast furnaces was as follow:—

	January, 1890.	December, 1890.	January, 1891.
Pig iron and spiegel iron...	65	66	66
Bessemer pig iron	9	9	10
Thomas pig iron	24	27	27
Foundry iron	28	30	31
	126	132	134

The Westphalian mine owners are forming an exclusive union. This union, whose place of meeting is at Essen, has notified by means of a circular that all workmen who should not have resumed their work before yesterday will be dismissed. This attitude has produced a very good effect on the workmen at the mines of Messrs. Krupp. The submission of the mine owners is very improbable, since they regard the strikers as not being thoroughly in earnest.

The Coal Market.—The chief feature of the past week was the spread of the strike among the Westphalian miners, which first broke out in the previous week. The first stoppage of work occurred on the 16th inst. On the 21st inst. the strike had affected six mines, and on the 24th inst. sixteen mines. During the past few days 9,189 workmen have been out on strike. The total number of the Westphalian miners is about 127,000. Even in the pits which are still in operation work is very slack, and stores of coal have been reduced to a minimum in consequence of the long winter. A deficiency in the supply of coal is therefore apparent, and high prices are quoted. The present Minister, in contrast with his attitude during former strikes, has advised the managers of the mines to flatly refuse all attempts at a compromise. Public opinion is decidedly against the miners, since it is generally recognised that their condition has been much improved during the last two years.

AMSTERDAM, 27th April, 1891.

Steamboat Companies.—It appears from the report of the directors of the Royal West-Indian Mail Packets Company in Amsterdam, that, after writing off a sum of £7,500, there remains for the year 1890 a net surplus available for dividend of £2,477, out of which a dividend of but 2 per cent. can be declared. This unfavourable result is owing to various circumstances. The gross earnings on passenger and goods traffic increased last year by 18 per cent., principally as a consequence of a larger number of boats running, the monthly service having been altered into one every three weeks. The working expenses, however, show a larger increase, whilst the competition of an English undertaking, opening a new service from London to Surinam direct, had to be met. The loss of the steamer "Prins Willem I.," and the rise in wages and the price of coal, also affected the net receipts. The report of the Steamship Company "Nederland" (Amsterdam-Java) is of a much more favourable character. The net receipts in 1890 resulted in an available balance of £56,694, the shareholders receiving a dividend of more than 9½ per cent. But for the loss of the "Prins Frederik," in June, 1890, the result would have been even better. The fortnightly mail service last year was kept up by twenty-five journeys out, and twenty-six journeys homeward, whilst the company employed besides two steamers of the "Phœnix" and five vessels of the Royal Mail Packets Company. Two new steamships—the "Prinses Sophie" and the "Prins Hendrik"—both built by Messrs. Caird, at Greenock—commenced running last autumn. Fifteen steamers, of an estimated value of £500,000, are now on the company's books. The directors state that the Government has renewed the old mail contract with the company pending the framing of a new one rendered necessary by the rejection, in 1890, of the Bill for the approval of a joint subsidised mail service by the "Nederland" and Rotterdam "Lloyd" Steamboat Companies.

STOCKHOLM, 25th April, 1891.

Manufactured Wood Industry.—The manufactured wood works in Sweden are, on the whole, doing well. The production is increasing, and the market is extending. The Bodafors Chair Manufactory turns out about 60,000 chairs per annum, which are distributed throughout Sweden, and are also exported to England, France, and Spain. Another prosperous establishment is the Ericsson Carpentry Manufactory at Orebro, which has recently secured some important contracts, mostly for the home market.

The New Warship "Thula."—The tenders for the building of this new warship have now been received, and show how near two competitors may be to each other in price. The tenders were:—The Motala Engineering Company, £79,333; the Kockum Engineering Company, £79,277; the Bergsund Engineering Company, £73,611.

The Miners' Strike.—The large miners' strike in the Norberg mining district has been compromised. The masters offered to leave the matter to the decision of a committee consisting of three men chosen by the masters, three men chosen by the men, with the chief of the official Mining Department as chairman. The committee was to fix the rate of wages at the Kallmora and other Norberg

Digitized by Google

mines. This offer was made on condition that the men returned to work before the 29th inst., and the men have since decided to do so. It may be worth mentioning that the Salvation Army did their utmost to bring about a reconciliation, and to dissuade the men from persisting in the strike.

THE STATE TELEPHONES.—The long distance telephones in Sweden, between Stockholm-Gothenburg and Stockholm-Malmö, continue to give great satisfaction. On the former there were 7,482 conversations during March, and on the latter 5,659 conversations.

SHIPMENTS OF WOOD PULP.—The export of wood pulp from Sweden during the month of March was as follows:—Chemical wood pulp (dry) 1,667,496 kgr., (wet) 1,106,592 kgr.; mechanical wood pulp (dry) 2,126,882 kgr., (wet) 641,000 kgr. The aggregate exports during the first three months of the present year amount to 17,249,998 kgr., against 14,123,000 kgr. during the corresponding period of 1890, and 9,924,000 kgr. during the corresponding period of 1889.

CHRISTIANIA, 25TH APRIL, 1891.

THE CHRISTIANIA CEMENT COMPANY.—This company is now in bankruptcy, which is a rare occurrence in Norway with such a large industrial undertaking. The share capital is £55,555, and the buildings, which were on a large scale, were completed last autumn, since which date the works have had plenty of orders. The installation was, however, much more expensive than was estimated, and the company has incurred liabilities amounting to about £47,000. With the present machinery the capacity is about 70,000 barrels of cement annually, but with an outlay of £5,500 it could be increased to 100,000 barrels. The bulk of the shares is in German and Swedish hands.

NEW TINWARE WORKS.—A new manufacture has been started at Skien, where the Stjernen Works have begun the manufacture of trays, boxes, and other descriptions of tinware. This is, we believe, the first industrial establishment of its kind in Norway.

THE HOLMENKOL ELECTRIC RAILWAY.—The projected electric railway to Holmenkollen will cost about £33,300, and the working expenses will be about £2,777 annually. The company intends to make a double line, and to run trains every two minutes.

COPENHAGEN, 25TH APRIL, 1891.

THE STEAMER "GEFION."—The steamer "Gefion," belonging to the United Steamship Company, Copenhagen, has just been lengthened 30ft. at the shipyard of Messrs. Burmeister & Wain, Copenhagen. The accommodation on board has been much improved, and the speed has been increased.

THE CRUISER "HEKLA."—The new cruiser "Hekla" has just had its engine trials in the Sound. It was launched in November last year, and will be ready this summer. The vessel has an armoured deck, is provided with powerful guns, and is fitted with torpedo-firing appliances and electric-light projectors. The engines are calculated at 3,000 i.h.p., and have been made at the Messrs. Burmeister & Wain's shipbuilding and engineering works, Copenhagen. The "Hekla" is 225ft. long and 33ft. broad.

NEW STEEL VESSELS.—A syndicate at Nordley, on the island of Fonö, has recently ordered four steel vessels from a Sunderland firm. The dimensions are:—Length, 175ft.; breadth, 30ft.; depth of hold, 16ft.; size, about 620 registered tons; and a dead-weight carrying capacity of about 980 tons. The price is £27,000 complete. A syndicate at Kolding has ordered a similar vessel from the same Sunderland firm.

MADRID, 27TH APRIL, 1891.

RAILWAYS IN THE SOUTH OF SPAIN.—The line which runs from Lorca to Huercal through a lead district has been opened for traffic. A new line of railway from Xerez to Arcos is projected. Arcos is the most important town in the province of Cadiz, and has at present no railway. It is stated that the southern system of railways, which is officially known as the Madrid, Alicante, and Saragossa line, intends to purchase the Andalusian system, which consists of a large group of lines with a safe and increasing traffic. The traffic on these lines will be still further increased when agricultural improvements are made in this district.

ELECTRIC LIGHTING AT MADRID.—Some progress is being made in electric lighting at Madrid, but the price is still very high. About 28,000 lights are served from the two central stations. The German company is at present using only one of their four large engines for driving the dynamos.

CONTRACT FOR ARMOUR PLATES.—It is reported that the Spanish Government are about to make a contract with the Creusot Works for 2,500 tons of armour plates to be used in the building of ships in the Government yards. A strong feeling has been expressed against this purchase, as it is thought that the Government will soon be able to obtain armour plates in sufficient quantity from the works of Mr. Martinez Rivas.

SHIPMENT OF ORES AT BILBAO.—There is a large and unexpected decrease in the shipment of ores at Bilbao. This decrease gives rise to some uneasiness, as arrangements had been based on a normal shipment of at least 3,500,000 tons of ores per annum. Bilbao has for the present lost the Italian market for hematite pig iron, and manufacturers must look forward to produce puddled iron or steel for sale in Spain.

NEW BANK AT BILBAO.—Although there is a branch of the Official Bank of Spain at Bilbao, and also a special local bank called the Bilbao Bank, which has very good credit, it is felt by merchants and by the industrial classes that there is room for a new bank, which should offer increased facilities. The granting of increased facilities implies greater risks on the part of the bank, but it seems probable that the capitalists who are starting the new bank will make it a success.

COAL IN THE PROVINCE OF ALMERIA.—It is reported that coal is to be worked in the province of Almeria. Though the coal is not of good quality, it will serve for many purposes.

ROME, 27TH APRIL, 1891.

THE OUTPUT OF MINES IN ITALY.—A report giving the total production of Italian mines in 1889 shows an increase of 38,240 tons over the production in 1888, valued at about £47,040, or an increase of 3·13 per cent. in the quantity and 2·19 per cent. in the value. The 726 mines in active work in the kingdom have given an aggregate output of 1,222,187 tons of various ores, valued at about £2,142,160. The production of 1888, compared with that of 1887, had shown an increase of 1 per cent. for the quantity and of 4·6 per cent. for the value. The larger quantity produced in 1889 is due to the larger number of mines or to the more active working of those in existence. The increase in the value of the production is not proportionate to that of the quantity, owing to the fact that the rise in the market prices has been limited to a few metals, such as zinc and antimony, whilst there has been a decline in the price of several ores. The increase, both as regards quantity and value, is mainly due, in order of importance, to the larger production of zinc ores, mercury, coals, lead ores, iron pyrites, asphalt and bitumen, antimony, and auriferous ores, &c. The larger decrease has been found in sulphur, copper ores (only in the value), silver ores, iron ores, spring salt, and boric acid. 48,981 workmen were employed in the mines, that is to say, 130 less than in 1888. The average annual production per man in 1888 was valued at £42 12s., whilst in 1889 it reached £43 14s. This fact seems to indicate an improvement in the management of the mines. The following table shows the production of the mines in Italy in the year 1889:—

Production of Ores.

Products.	Number of Mines Worked.	Production. Quantity Tons.	Value in Units. Lire.	Total Value. Lire.	Number of Men Employed.
Iron ores	43	173,489	10·88	1,887,231	1,418
Manganese ,,	5	2,203	23·51	51,801	46
Copper ,,	16	48,214	27·82	1,341,528	1,300
Zinc ,,	102	97,059	85·08	8,257,775	10,587
Lead ,,		36,894	191·42	7,062,348	
Silver ,,		1,997	875·64	1,748,663	
Gold ,,	20	10,932	46·50	508,427	451
Antimony ,,	5	563	177·75	100,072	328
Mercury (metal)	9	385	5090 00	2,274,450	533
Iron pyrites	4	17,022	14·48	246,494	343
Coals	37	390,320	7·32	2,858,154	2,714
Sulphur	419	371,494	66·36	24,652,876	29,028
Salt	19	28,490	—	556,633	635
Asphalt, bitumen, & petroleum, also mineral waters	28	33,521	—	620,532	996
Aluminite	1	5,600	25·00	140,000	76
Boric acid	11	2,473	500·00	1,236,550	99
Graphite	7	1,531	7·00	10,271	27
Total	726	1,222,187		53,554,255	48,931

In my next letter a table will be given showing the production of the metallurgical and chemical works.

NEW YORK, 18TH APRIL, 1891.

A NEW PULLEY COVERING.—A very reliable and inexpensive pulley covering has recently been brought out by the Burt Pulley Covering Company, 385, Washington Street, Buffalo, N.Y. It is known as Brazilian gum pulley covering, and is applied by means of a brush to the pulley, four coats being put on. After the last coat is on, the gum is allowed to harden for twelve hours, and then the face of the pulley is oiled with castor oil or any good belt dressing and the belt put on. This covering is guaranteed to prevent slipping of the belt, and is as simple as it is efficacious.

NO DUTY ON RECOVERED SULPHUR.—The classification of recovered sulphur as refined brimstone, subject to duty at the rate of $8 per ton, has been overruled by the Board of Appraisers, U.S.A., which decides that the article is entitled to free entry as crude sulphur.

"WHALEBACK" STEAMER.—The "whaleback" steamer "Colgate Hoyt,' which was described and illustrated in *Industries* some months ago, has developed another good quality in addition to those already claimed for her by her builders. Her captain reports that on a winter trip she proved herself a first-class icebreaker, the peculiar form of her bow working away and breaking up easily the ice which was forming rapidly on the lake as she came through. The whaleback ships are to be tried on the ocean as well as on the lakes, one being under construction which is to be sent through the canals to the Atlantic. This boat will be employed in carrying iron ore from Cuba to the United States.

THE WORLD'S FAIR AT CHICAGO.—Progress in the arrangements of this Exhibition is being rapidly made. The following table, giving a comparison between previous Exhibitions and the present one, will serve to show on what a large scale the Exhibition at Chicago in 1893 is to be held:—

Where Held and Year.	Total Acreage.	Square Feet Under Roof.	No. of Days Open.	Receipts.	Guarantee.
London, 1851...	21½	700,000	144	£356,000	English Govt.
Paris, 1855...	24½	1,866,000	200	128,000	French Govt.
London, 1862...	23½	1,291,800	121	328,852	English Govt.
Paris, 1867...	87	3,371,904	217	420,735	French Govt.
Vienna, 1873...	280	—	186	—	£900,000
Phila., 1876...	236	1,688,858	159	762,745	£500,000
Paris, 1878...	100	1,858,778	194	506,330	—
Paris, 1889...	173	1,000,000	183	1,660,000	£720,000
Chicago, 1893...	1,037	3,579,000	179	—	£3,088,870 to Mar. 31st

The Société des Chemins de Fer Glissant, of Paris, has made application for permission to erect a two-mile track on the Exhibition grounds at Chicago for the purpose of showing the hydraulic sliding railway, which was in operation during the Paris Exhibition of 1889. The cars slide on a film of water, and are propelled by jets of water thrown out from turbine pillars erected along the track.

PHILADELPHIA, 17TH APRIL, 1891.

THE COKERS' STRIKE.—During the last few days there has been a steady increase in the number of applications for work by the cokers in the Connelsville region, and the shipments of coke, although still small, are increasing rapidly. The evictions of men from the houses belonging to the Frick and McClure companies continue, and it is stated that a number of Hungarians will be sent from the East to take the places of the strikers. It is evident that the men were not prepared for such a long strike, since the men who are daily going back to work are driven to do so by actual necessity. The 10th Regiment will be withdrawn at the end of the week, and the companies fear there will be further disturbances. There are still 14,000 men out on strike.

THE PENCOYD IRON WORKS.—Work has been resumed during the day in the big mill of the Pencoyd Iron Works. The men are willing to return to work until July, and then sign a scale for the ensuing year. The steel department of the works has been running steadily since the beginning of the strike.

THE REMOVAL OF THE DELAWARE ISLANDS.—Tenders have been received for the removal of 18,000,000 cubic yards of material, 18,000ft. of temporary wharfing, depositing 2,500,000 cubic yards of the former on League Island, which constitute the proposed improvement to the Philadelphia Harbour. The tender of Messrs. James A. Mundy & Co. amounted to £445,840, that of the Penn Dredging Company to £733,600, and that of the American Dredging Company to £683,600. The specifications include the formation of a channel about 2,000ft. in width, and about 55,000 square feet in cross section at mean tide. The work is to be commenced on or before May 15th, 1891.

PROBABLE STRIKE OF MINERS.—The Convention of Miners and Mineowners at Pittsburg has terminated suddenly because the Conference Committee has failed to come to an agreement upon the eight hours question. This abrupt termination means that the friendly relations which have hitherto existed between the two classes have come to an end. It means also that 75,000 miners will stop work on May 1st, and that, directly or indirectly, 500,000 men will be affected.

NAVAL.—The Navy Department has authorised the payment to Messrs. W. Cramp & Sons of the second instalment of the price to be paid for cruiser "No. 12," the 21-knot vessel known at the Department as "The Pirate." This payment was made upon evidence that one-fifth of the work of construction had been completed. It has also authorised the tenth payment of £17,910 to be made on the armoured cruiser "No. 2," known as the "New York," also building at the yards of Messrs. Cramp. This is an indication that one-third of the work upon the vessel for which the contract was signed last July has been completed. The United States coast defence vessel "Monterey," now in course of construction at the Union Iron Works, San Francisco, will be launched on the 28th inst.

RAILROADS.—A new railroad has been incorporated to connect Chicago and Indianapolis by a direct line. The name is the Indianapolis, Longspirt, and Chicago Railroad, and the capital is £800,000.—The annual report of the Chicago, Burlington, and Quincey Railroad shows gross earnings of £5,555,180; expenses, taxes, rentals interest on bonds, and sinking fund, £5,038,600; net earnings £506,500; dividends, at the rate of 5 per cent., £763,900.

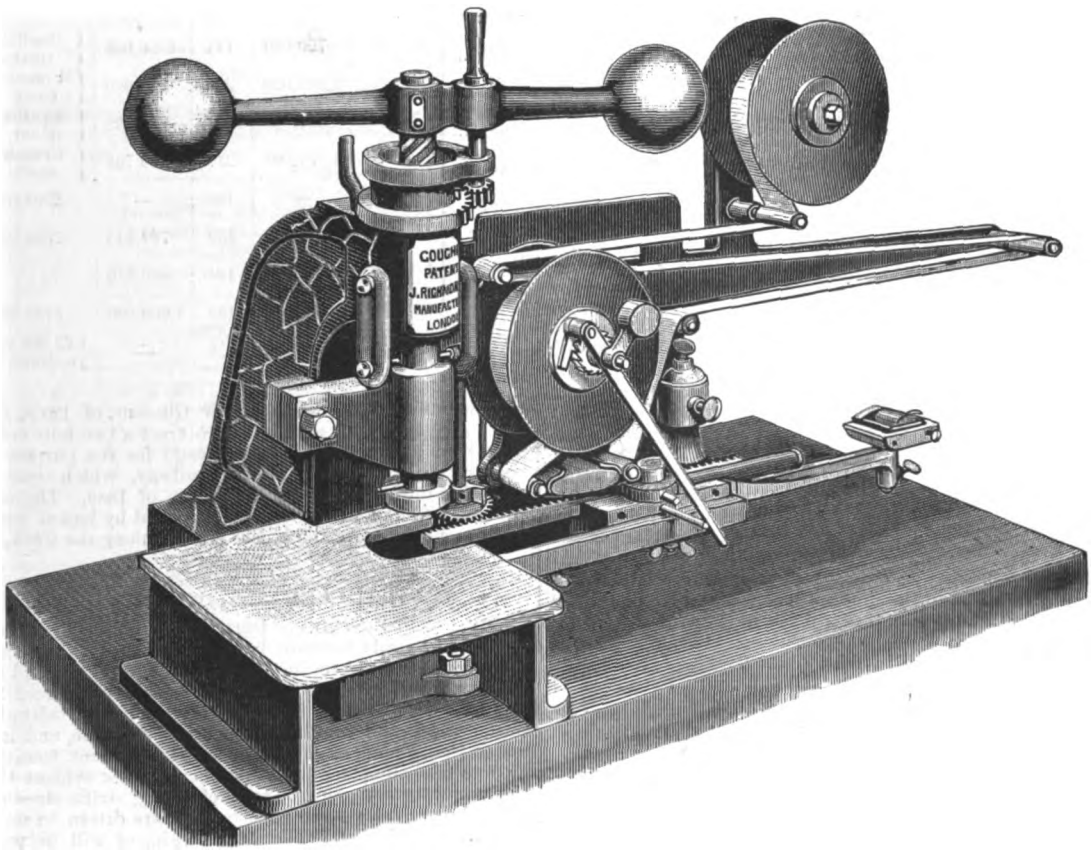

FIG. 2.—GENERAL VIEW OF PRESS.

NOTES ON PATENT LAW.

III.

(*Continued from page* 352.)

WE have in the present article to consider what exactly is meant by an invention in patent law. The importance of doing so arises in two ways—first, because only an invention can be patented, that is to say, can be the subject of a patent grant; and, in the second place, because it is in respect of his patented invention only that a patentee has any rights. But though it has to be considered in these two distinct lights, it will be found that the word itself is in no degree ambiguous. A perfectly definite meaning has been assigned to it, and although it may sometimes be a matter of difficulty to express that meaning in exact words the difficulty arises as a difficulty of expression and not of thought.

The easiest way of approaching the technical definition of the word is to call to mind its common meaning. We speak of that as an invention which any person has devised or contrived for a distinct purpose. Thus a story told, not because it is true, but because it will, though untrue, serve a purpose, is said to be an invented story. An instrument contrived to accomplish a given object is said to be invented with that object, and similarly anything else such as a formula, or a shape, or an expression, or an argument, which is capable of originating in the mind and subserving a purpose, is commonly called an invention. Of inventions of this class the mental original is the essential feature. There is another sense of the word "invention" which is now almost obsolete, but is preserved in a few technical expressions—the old Latin sense of discovery. Thus, the Empress Helena is spoken of as the "*inventress* of the true cross," the meaning not being that she originated the legend which identified a particular piece of wood with the true cross, but that she discovered the genuine thing.

Now, both these senses are included in the word "invent" as used in patent law. It is equally invention to originate and to discover a novelty. Hence it is not necessary for a patentee to satisfy the Crown that he has come into possession of the idea which is embodied in his invention in one or other of these ways. In either case he may be the inventor, if only the idea is a secret known to him. Indeed, for this purpose the word discover must be understood in the most extended sense. It conveys, perhaps, according to its common use, the sense of learning from the study of nature or by the process of reflection; but for present purposes it is not to be confined within any such limits. If a man were to go abroad, say, to Japan, and there learn by observation the art of lacquering, he would, upon introducing that art into this country, be as truly and as fully its inventor as if he had acquired it by the process of experiment in his own laboratory. So that it is correct to say in the most comprehensive terms that, by whatever means a man becomes possessed of a secret, provided it becomes *his* secret, he is for the purposes of patent law its inventor. To this extent the technical meaning of the word is larger than its ordinary sense.

But the vast body of things that can thus be called inventions is much cut down when we come to inquire what inventions are patentable. Here, again, we may advance a long way towards our conclusion upon a very well-known path, for it is commonly enough understood that a patentable invention must have something to do with merchandise. Everybody appreciates, to a greater or less extent, the ingenuity and originality of Darwin's theory of the origin of species, but nobody would for a moment suppose that Darwin could have taken a patent for it. It could not be embodied in any material thing, which should be either a presentation or a result of the theory. But, on the other hand, when working upon Darwin's theory of variation, M. Pasteur succeeds in producing a new and protective variety of some dangerous bacillus, the secret root of anthrax or of hydrophobia, for example, there is no doubt that if he chose he might obtain a valid patent either for the ameliorating process or for the medicinal lymph in which it results. The mere abstract idea cannot be monopolised, but when it has taken shape in some concrete substance it becomes fit subject for a patent grant. So much will be readily understood, but it is necessary to be somewhat more precise, for this is a topic which has been much discussed, and upon which the law has been laid down with great accuracy. The word has received statutory definition by the Patent Act of 1883, which says that it means "any manner of new manufacture the subject of letters patent and grant of privilege within section six of the Statute of Monopolies." The passage here referred to was quoted in our first article. The material words may, however, be usefully quoted again. They are to the effect that letters patent and grants of privilege may be made "of the sole making or working of any manner of new manufactures within this realm to the first and true inventor and inventors of such manufactures which others at the time of making such letters patents and grants shall not use, so as also they be not contrary to law, nor mischievous to the State by raising prices of commodities at home or hurt of trade or generally inconvenient."

The word "manufacture" in this clause has supplied the test by which all new abstract ideas have been tried and found wanting when proposed as subject matter of a patent. A new theory, for example, is plainly not a "manufacture," which, as was said by Lord Kenyon in a celebrated case, means "something made by the hands of man." But although the meaning of the term has been thus strictly observed, it has not been by any means narrowly defined. Whatever can be worked or made has been held to fall within it, and accordingly a manufacturing process or a manufactured product has been equally included. This comprehensive definition is, however, subject to one curious restriction, of doubtful authority, perhaps, at the present day, but still of sufficient importance to merit notice here.

It has been said that to support a patent there must be some *useful* and *vendible* article, the subject of the patent, if it be a patent for a manufactured article, or the object of the process, if it be a patent for a method of manufacture. This is, perhaps, a fair inference from the ordinary sense of the word manufacture, but it is a distinctly unfortunate one, because it establishes a most arbitrary distinction between useful inventions, and has the effect, if now sound law, of shutting out from the protection of the Patent Act the whole class of most meritorious inventions which are directed, not to the production of useful articles, but to the rendering innocuous of such as are naturally noisome. At the present time, when questions of sewage disposal have attained to vast and still growing importance, the question is one of no slight significance, and certainly the authorities, as they stand at the present moment, appear to show that deodorising processes and other similar methods of treatment intended to make sewage matter, not vendible, but only harmless, are not capable of being patented.

There is another class of inventions, often said to be incapable of being protected by a patent grant—namely, medicines—but in this case there would seem to be some misapprehension of the law. The fact is that what are commonly called *patent* medicines are not *patented* medicines. On the contrary, they are, many of them, secret compounds, and more accurately termed proprietary medicines. By an infelicitous convention they have come to be called patent medicines, although neither historically, nor at the present time, has their liability to stamp duty borne any ascertainable relation to patent grants. But although this is the case of so-called patent medicines, the proprietors of which choose, as a rule, to trade upon a reputation for secret knowledge rather than to accept the conditions of a patent grant, there seems no reason to doubt that any such medicine might be protected in this latter way if its inventor chose to make the necessary application. Indeed, at the time when the meaning of the word "manufacture" was a subject of discussion in the Courts the case of a medicine was more than once put forward by the judges, who defined the law as the very type of a patentable article.

But, although an abstract principle cannot be the subject matter of a patent, it may in a proper case be very effectively protected by a patent. This result, which, thus stated, appears, perhaps, paradoxical, is brought about in the following way. The Courts have always held that a substantial infringement of a patent is not rendered the less an infringement by the circumstance that the infringer has taken pains to introduce differences for the purpose of obscuring the essential identity of what he has made with what the patentee has protected. If such colourable imitations were allowed to pass, it is clear that the protection afforded by the grant would become illusory. It is therefore, in most cases, a matter of prime importance to ascertain what are the essential constituents of the invention. If its essence has been taken by the infringer, he will be held liable notwithstanding any ingenuity that he may have displayed in devising distinctions in respect of non-essential parts. If, therefore, the essence of an invention consists in the application of a new principle, the patentee is entitled to claim protection in respect of any possible application of the same principle, even although the mode of applying it which is complained of be totally distinct from anything that he had thought of, on the ground that other methods of working out the same principle are only colourable imitations of his invention. In one case a plaintiff successfully established a claim to

Digitized by Google

the broad principle of applying detonating powder to the discharge of firearms. In that case the infringer adopted a form of gun-lock unlike any that the patentee has described, but, inasmuch as his lock was constructed upon the principle of using detonating powder in a manner like that which had first been disclosed by the patentee, it was held that he had committed an infringement. Moreover, in the case of *Jupe* against *Pratt*, which is constantly quoted in the Courts as an authority upon this point, the rule of law was laid down by Baron Alderson in the clearest terms, to the effect that "You may take out a patent for a principle coupled with the mode of carrying the principle into effect, provided you have not only discovered the principle but invented some mode of carrying it into effect." Thus the rule against patents for abstract principles has been carefully guarded so that it shall not in effect restrict the legitimate scope of the protection afforded to an inventor, however large may be the scope and reach of his invention, while, on the other hand, it has been effectively asserted in such a sense as prevents any would-be monopolist from laying hands upon the forces of nature by the shallow device of inventing new phrases by which to describe them.

There is one point which, though really involved in what has been already said, may be usefully stated in express terms, as it is perhaps otherwise apt to become a source of doubt and even of perplexity. It is this—an invention is none the less invention in the sense of being new because the novelty consists in the putting together of old parts in a new combination. This was decided long ago, and one of the early cases affords a striking illustration of the point. There the patentee invented a machine for cutting cloth *crosswise* by means of rotary cutters. The use of rotary cutters for cutting cloth *lengthwise* had been known and practised before the date of this invention, but for cutting across its breadth shears only had been employed. It was held that a patent limited to the particular use of rotary cutters in the new way was valid, for although the materials were old the application of them and the mode of that application were new. Indeed, it is obvious that in a broad sense almost every invention consists, and must of necessity consist, in the combination of old parts in a new manner. The case mentioned shows that the novelty is sufficient, although the departure from what has been done before be very slight, if at the same time it be perfectly definite.

So also an invention is not the less original because it is grounded upon another distinct invention as a foundation. A case of this sort was heard by the great Lord Eldon, who said, "If the petitioners have invented certain improvements upon an engine for which a patent has been granted, and those improvements could not be used without the original engine, at the end of fourteen years" (that is, fourteen years from the date of the patent for the engine) "the petitioners could make use of a patent taken out under their improvements, though before that period expired they would have no right to make use of the other's substratum. At the end of that time, the public has a choice between the patents." This dictum expresses what is now the undoubted law upon this head.

The foregoing remarks will have conveyed to the reader's mind what may be made the subject of a patent. Perhaps it is safer not to attempt to summarise their effect in any accurate definition, but, subject to the curious question about inventions which are directed not to the production of useful articles, but to the amelioration of such as are mischievous, it may be broadly said that all inventions which are capable of becoming property in the hands of their inventors may be protected, and that, save in so far as they are subject to the laws relating to literary or artistic copyright, or the registration of designs and trade marks, they may be protected by letters patent.

So much must suffice under the head of what inventions are patentable. It is plain that the inventor of a patentable invention may apply and actually obtain protection for something less or for something other than he has invented. In other words, an important difference comes into view as soon as we pass from the consideration of what is a *patentable* to the consideration of what is an actually *patented* invention. But this further point we must reserve for our next article.

(*To be continued.*)

Notices of Meetings.

THIS WEEK.

DECIMAL ASSOCIATION.—Friday, May 1st, at 3 p.m. General meeting.

ROYAL INSTITUTION.—Saturday, May 2nd, at 3 p.m. Lecture IV., on "The Dynamo," by Professor S. P. Thompson.

NEXT WEEK.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.—Monday May 4th, at 8 p.m. Annual general meeting.

SOCIETY OF ENGINEERS.—Monday, May 4th, at 7.30 p.m. Paper to be read: "Modern Coal Gas Manufacture," by Mr. C. C. Carpenter.

SOCIETY OF CHEMICAL INDUSTRY.—Monday, May 4th, at 8 p.m. Papers to be read: "An Improved Process for Softening and Clarifying Water," by Mr. L. Archbutt and Mr. R. M. Decley; "The Chemistry of Whisky and Allied Products," by Mr. A. H. Allen.

INSTITUTION OF CIVIL ENGINEERS.—Tuesday, May 5th, at 8 p.m. Ordinary meeting. Paper to be read, with a view to discussion: "On Railway Train Lighting," by Mr. W. Langdon; also monthly ballot for members and (at 9 p.m.) reception by the President and Council.

IRON AND STEEL INSTUTUTE.—Wednesday, May 6th, Thursday, May 7th, and (if required) Friday, May 8th, at 10 a.m. Papers to be read: "On the Ironmaking Resources of the Southern States," by Professor J. R. Procter; "On the Coke Industry of the United States," by Mr. J. D. Weeks; "On the Manufacture of War Material in the United States," by Mr. W. H. Jaques; "On Tests for Steel used in the Manufacture of Artillery," by Mr. Wm. Anderson; "On Certain Pyrometric Measurements and the Method of Recording Them," by Professor Roberts-Austen, F.R.S.; "On the Changes in Iron Produced by Thermal Treatment" (supplementary paper), by Dr. E. J. Ball; "On a Graphic Method of Calculating the Composition of Furnace Charges," by Mr. H. C. Jenkins; "On the Calorific Efficiency of the Puddling Furnace," by Major L. Cubillo; "On Economical Puddling and Puddling Cinder," by Mr. Thos. Turner; and "On the Micro-Structure of Steel," by M. Osmond.

SOCIETY OF ARTS.—Wednesday, May 6th, at 8 p.m. Paper to be read: "The Sources and Applications of Borax," by Mr. E. L. Fleming.

INSTITUTION OF ELECTRICAL ENGINEERS.—Thursday, May 7th, at 8 p.m. Papers to be read: "On Some Effects of Alternating-Current Flow in Conductors having Capacity and Self-Induction," by Dr. J. A. Fleming; "Some Points Connected with Mains for Electric Lighting," by Mr. W. H. Preece, F.R.S.

CHEMICAL SOCIETY.—Thursday, May 7th, at 8 p.m. Papers to be read: "The Action of Alkalies on the Nitro-Compounds of the Paraffin Series," by Professor Dunstan and Mr. T. S. Dymond; "The Addition of the Elements of Alcohol to the Ethereal Salts of Unsaturated Acids," by Professor Purdie and Mr. W. Marshall; "On Some New Addition Compounds of Thiocarbamide affording Evidence of its Constitution," by Professor E. Reynolds; "On the Action of Acetic Anhydride on Substituted Thiocarbamides, and an Improved Method of Preparing Aromatic Mustard Oils."

PRICES CURRENT, 29TH APRIL, 1891.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER continues inactive, with small business. No change of importance has taken place during the week, although values of Chili bars have been unsteady. On the 27th inst. prices touched as low as £50 12s. 6d. cash, but have since improved, and are to-day £51 2s. 6d. to £51 10s., with firm market. Manufactured £64, "strong," with small demand.

TIN: Strong, at advancing rates, values of spot foreign being about 17s. 6d. to 20s. higher on the week.

LEAD: Steady, with practically no change in prices.

SPELTER: Again easier.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS: The demand for bleaching powder is well maintained, but for caustic soda there is less inquiry, and for large lots some concessions in price may be obtained. Soda ash of all qualities moves off steadily. Sulphate of copper is again lower, supplies being very plentiful and buyers few. Oxalic acid is more freely offered. Yellow prussiate of potash is firm at the advance.

HOME INDUSTRIES.

LONDON, 30th April, 1891.

The Money Market.—Money has been growing steadily dearer all the week, though gold began to arrive at the Bank in considerable quantities. The Bank was in the market taking what steps it could to make the official rate effective in drawing money to this centre. Now that the outside market is fairly in line with the central institution, the probabilities are that, though the half-yearly drain to Scotland will weaken the position, no serious increase in monetary tightness need be feared. The stock markets have been fairly active, though the amount of business is still on a restricted scale. This week the Stock Exchange is closed on Friday and Saturday, and a week that begins with a settlement and ends with a holiday is not the most favourable for encouraging new commitments. Besides, there was a severe check at the start—a set-back in Wall Street, and a recrudescence of rather alarming rumours about the position of the Paris Bourse—which depressed all values. The market managed to get over the scare pretty soon, and American securities above all have shown a good deal of staying power. The "boom" in them seems fairly established, and should be maintained, with occasional reactions, for a month or two, if we may judge from the prevailing conditions in New York. Home railways have exhibited a somewhat firmer tendency, but are still far from brisk. In foreign securities there is little interest and less animation. In the minor departments business is almost neglected, the greater activity in mining shares having diminished again. Miscellaneous securities are virtually idle.

The Coal Trade of London.—The enormous growth of the coal trade of the metropolis has been brought out very prominently in the evidence submitted in support of the Manchester and Sheffield Railway extension to London. In 1863, the year when the extension of the Midland line to London was sanctioned, the total amount of coal brought into London by all the railways was 1,775,000 tons. The Midland line was completed to London in 1868, and in the following year the quantity of railway-borne coal entering London was 3,341,000 tons. In 1879 this quantity had increased to 6,547,000 tons, and in 1889 it had risen still further to 7,877,000 tons. The sea-borne coal has not increased at anything like the same rate, but still it has materially expanded. In 1863 the amount which came into London by sea was 3,335,000 tons, and in 1889 it was 4,765,000 tons. We have thus a total of 12,637,000 tons coming into the metropolis in a year.

The Wool Trade.—Messrs. Helmuth, Schwartze, & Co., in their report on the wool trade, state that in the second series of London sales of colonial wool which commenced on the 2nd inst., and closed on the 28th inst., a total of 284,292 bales were catalogued, as against 305,906 bales in the corresponding series of last year. The quantity held over from the preceding sales amounted to 10,000 bales, and the new arrivals to 346,500 bales, of which 73,500 bales were forwarded direct. The total of first-hand wool actually available was therefore 283,000 bales, of which 274,000 bales have been sold (119,000 bales for home consumption, and 155,000 bales, including 9,000 bales for America, for export), leaving 9,000 bales to be carried forward to next series.

The Institution of Mechanical Engineers.—The annual dinner of the above Institution was held yesterday evening at the Criterion, Piccadilly, and was presided over by Mr. Joseph Tomlinson, President of the Institution. There was a very large attendance. Among those present were Sir James Douglass, Sir James Kitson, Sir John Coode, Sir Frederick Abel, Sir Douglas Galton, Sir R. Rawlinson, Mr. Alfred Giles, M.P., Mr. George Berkley, and Professor Kennedy.

Report on Injurious Insects and Fungi.—In the annual report of the Intelligence Department on Injurious Insects and Fungi, which has recently been issued by the Board of Agriculture, it is stated that arrangements had been made with the Post Office for the distribution of leaflets on crop attacks in country districts. Recourse has been had to this method during the past year in the case of the Hessian fly leaflet, and in that on the winter moth. Posters and enlarged illustrations of the insects whose detection is desired have been exhibited by the post offices in country districts. Reference is made in the report to the use of sulphate of copper as a remedy for the potato disease, which is recommended by reason of its success in some American experiments made last year. The report suggests that the sulphate of copper washes should be tried in Great Britain and Ireland, not in a half-hearted manner and when the disease is established, but as a preventive measure adopted as the Continental wine producers adopt it, and as the English hop-growers adopt sulphur, as almost a necessary part of cultivation.

Business Announcements.—The Duke of Marlborough has been appointed chairman of the Brush Electrical Engineering Company, Limited, in succession to Lord Thurlow, who has resigned his seat at the Board of that company. The Secretary of State has appointed Mr. A. A. Campbell Swinton to be permanent consulting electrical engineer to the Metropolitan Police.

Decimal Association.—A general meeting of the members of this Association will be held at the London Chamber of Commerce, Botolph House, Eastcheap, to-morrow, at 3 p.m. Mr. S. Montagu, M.P., President of the Association, will preside.

MANCHESTER, 30th April, 1891.

The Ship Canal.—The negotiations have been proceeding with the Salford Borough Council with reference to the promotion of a Bill empowering them to subscribe £1,000,000 towards the amount necessary to complete the Ship Canal. The Manchester authorities had expressed their opinion that it would be hazardous to introduce any new clauses into the Bill, but were willing to aid Salford to obtain a separate Bill. To this course the Salford Corporation has finally objected, and the Manchester scheme will therefore be pushed forward with all speed.

Cheap Gas.—A determined effort is being made to arouse public interest in the question of supplying gas at cost price. This subject has been discussed for some time and has been received with much public favour. It is desired to develop the use of gas for heating and motive power, the present price charged in the city being too high to permit of economical employment. The movement is a part of the general scheme for the purification of the atmosphere in Manchester.

The Engineering Trades.—Although the prevailing topic in engineering circles is the shortening of the working hours, the demand of the workmen has been so far conceded by a number of the largest employers that the question may be considered practically settled. There has been a partial cessation of work, but this has only applied to a few concerns, and, the majority of the Manchester engineers having agreed, it is felt that the others must follow. At present the movement is confined to the immediate vicinity of Manchester, but the outside towns will probably have to follow suit. In spite of the disturbances in the labour market engineers continue to be well employed. Although there is a general feeling that the best of the trade has gone, there is yet ample employment for many months, and no trace of depression is as yet perceptible. Boiler makers and bridge builders within the district are fully employed, and general ironfounders are also well engaged. Machine tool makers do not experience much falling off in the demand, inquiries both for home and abroad being numerous. Textile machinists are still exceptionally busy, there being a number of orders unexecuted. All the various firms engaged in this industry are so full that the execution of orders is much delayed. Messrs. John Hetherington & Sons, Limited, have acquired a large plot of land, with the buildings upon it, in order to extend their premises. Many other firms could usefully employ more plant and space than at present. There does not appear to be quite as much activity in the floating of new mills, although the results of the recent stocktakings have not been unsatisfactory. It is felt, however, that for the present the extension has been large enough, and it is a remarkable testimony to the vitality of the cotton trade that notwithstanding the increased competition new spindles are still being started.

The Linen and Jute Trades.—There has been a continuance of that firm feeling to which reference has been made in previous reports. Although merchants are not specially busy manufacturers will not make concessions in yarns, which have been dear for some time past. Prices for some descriptions are stiffer, both home and continental spinners being determined to hold out for better prices. Concerning piece goods, coarse Forfar makes are steady, but sales in this market display no feature of special interest. Hessians move off quietly. Handkerchiefs are in very fair demand, both in the L.C. and cotton end. The embroidery of these goods by the Swiss machine is said to be increasing in the St. Gall district, but goods so ornamented have not been placed to any extent on the local market. During the past three months extensive sales of Dundee printed jute carpets have been made in this district. The trade is a rapidly growing one, the sale of these carpets and of tapestries having been to a large extent responsible for the decline in the popularity of the old-fashioned "Kidder" or ingrain carpets. Other descriptions of fancy jute fabrics also sell well just now, their cheapness being a recommendation during times of general dulness when the more costly floor coverings cannot readily be sold. Linen threads have a steady sale. Shipments have fallen off slightly of late, but not in proportion to the decline in other branches of the export trade.

GLASGOW, 30th April, 1891.

Scottish Railways.—The sudden death in London on the 25th inst. of Mr. John Walker, the general manager of the North British Railway Company, has led to a fall of about 20s. in North British Railway stock. Mr. G. B. Wieland, secretary of the company, has been appointed general manager, pro tem. The difficulties that have arisen in connection with the construction of the Central Railway, which is at present being constructed through the centre of the city, seem in a fair way to be removed. The relative powers of the railway company under their Acts of Parliament and of the Corporation have been referred to arbitration, and in the meantime, separate plans are being lodged and separate applications for authority to deal with each street that requires to be opened up, as occasion arises.—The Lanarkshire and Dumbartonshire Railway Company has come to an arrangement with the authorities in Glasgow and in Partick with reference to their utilisation of an old bridge across the River Kelvin. The arrangement involves the payment to the railway company by the Bridge Trustees of £1,000, for which sum the railway undertakes to provide a new bridge 50ft. wide with an approach of the same width.

Telephony.—The National Telephone Company are about to carry a direct trunk wire from Glasgow to Carlisle *vid* Dumfries. This extension of the telephone system will place Glasgow in communication with Cumberland and Westmoreland, the system having been already extended into the mineral districts from Carlisle. In view of the intimate connection between Glasgow and the North of England, especially as regards the iron trade, this extension of facilities for the use of the telephone ought to be a great advantage.

Minerals.—In the beginning of the week pig iron rose sharply, on the 27th inst. 7½d. per ton, and on the 28th inst. another 7½d., making 1s. 3d. in two days.—Preparations are being made at Paisley Harbour for the discharge of iron ore. Coal shipments from the Scottish ports are still increasing, last week's increase being 30,044 tons. The shipments at Glasgow, however, again show a falling off, the East Coast ports and some of the smaller ports on the West Coast having succeeded in diverting some of the trade and in securing the increase.

Labour Questions.—A very singular dispute has arisen in Greenock in connection with the lengthening of the steamer "Rome" by Messrs. Caird & Co. for the Peninsular and Oriental Company. The plan hitherto adopted in lengthening steamers has consisted in cutting the vessel in two, separating the halves, and in inserting frames and plates to join the pieces, thus making up the required length. In the present case, however, the forward part of the vessel has been cut off, and an entirely new bow built. The rates for rivet work are 30 per cent. higher for old than for new work, and the dispute centres upon the question whether the construction of the bow is old work or new. Messrs. Caird & Co. hold the view that the riveting of the new part is new work, and should be paid for as such, while the riveting necessary to join the new part to the old is old work, and should be paid for at the advanced rate. The men, on the other hand, regard the whole of the work as old work, and demand payment for it as such. The Greenock branch of the Boiler Makers' Society has decided that the matter is one which Messrs. Caird's men must decide for themselves, but that, if they should decide to strike, the society would support them. Messrs. Caird's men thereupon, by a majority, decided to strike. New questions frequently arise in connection with trade union restrictions in consequence of rapid developments of industrial methods. This is the first instance of a dispute precisely of this kind. The dispute that threatened to disturb the local iron founding industry seems likely to be settled. The men have, it is stated, expressed their willingness to agree to a reduction of ¼d. per hour on time wages and 2½ per cent. on piece wages. This is a compromise which, if accepted by the employers, will avert a strike. The employers had intimated a reduction of 5 per cent. upon piece work. At a meeting held in Glasgow last week it was announced that 30 per cent. fewer men were employed than at this time last year.

Freights.—The freight market in Glasgow is fairly strong. The unfixed tonnage of sailing vessels for Calcutta is only 3,000 tons, and from Calcutta, 5,000 tons. Freights: Calcutta to U.K. or Continent, 36s. 3d. deadweight, 38s. 9d. for linseed. June sailing: Cardiff to San Francisco, 10s. 6d.; San Francisco home, November, 44s. 6d., and December, 43s. 9d. Steamers: Rangoon to Levant, 36s 3d.; Manila to U.K., 42s. 6d.; Bombay to U.K., May, 25s. 6d., June, 24s. 6d.

(From our own Correspondents.)

LIVERPOOL, 29th April, 1891.

The Vyrnwy Pipe Line.—The Board of Trade has sanctioned the laying of the temporary pipe line across the Mersey bed at Fidler's Ferry, notwithstanding the strong protest of the Warrington Corporation. The construction of the pipes is now well advanced, and they will soon be ready for laying, so that there is every prospect of the Vyrnwy water being supplied in time to prevent the dangers of the threatened drought. The permanent work under the river is now progressing more favourably, most of the obstacles having been overcome or removed. The condition laid down by the Board of Trade is that the temporary pipe line must be removed before the end of December, 1892.

The Cold Storage and Refrigerating Company.—The new premises of this company, which are being built on the site of the old Theatre Royal, are now far advanced. The building is nearly completed, and most of the machinery and apparatus, which has been designed by Mr. M. C. Bannister, Assoc.M.Inst.C.E., is either erected in position or is ready for erection. The works, when completed, will be one of the most extensive in the country, and will be fitted with all the most recent appliances.

SHEFFIELD, 29th April, 1891.

The Iron and Steel Trades.—A very quiet tone prevails throughout the steel trade, and few new orders have come in lately to replace the old ones, which are being completed. For the last two weeks there has been a considerable reduction in the output generally, which is due to the fact that quite one-quarter of the workmen are off work owing to the prevalence of the influenza. Prices for finished material have not much decreased, although it is confidently expected that a reduction must soon be made. There is a

Digitized by Google

fair amount of business in general blooms for ordinary trade purposes, and also in special forgings suitable for millwork. The steel casting business is quite stagnant, with the exception of a few details for agricultural machinery and odd parts required by marine engineers for repairs. Pattern makers are working short time, and engineers have little new work in progress. The cutlery trades are very quiet, and there are two serious disputes unsettled. File makers are only moderately busy, while cutters are now feeling the effects of so much machine-cut work. The building trades are brisk all round, and the contract for a new Town Hall has been placed, the total cost of the structure being estimated at £100,000.

COAL.—There is practically no change in the coal trade. The demand continues brisk at recent prices. Gas coke is selling at 14s. to 16s. per ton, and the harder and better qualities at increased rates.

THE FIFTY-THREE HOURS' MOVEMENT.—It is not anticipated that any strike will occur here in reference to this question, as most of the works in other districts have already conceded the demands of the men. The result of the meeting of the employers will be made known shortly.

NORTH STAFFORDSHIRE, 29TH APRIL, 1891.

THE IRON TRADE.—Great competition still prevails for any orders on the market, and prices are weak in consequence. Bars are being sold at from £5 17s. 6d. to £6 per ton, delivered at Liverpool or port of equal facility, and pig iron is not worth more than about 42s. 6d. at works. Notice for a reduction in wages has been given to the blast furnace men, and expires on May 2nd. Several forges have stopped work owing to the unremunerative state of the trade.

THE COAL TRADE.—There is still a large demand for house coal, and prices remain the same. For pottery and manufacturing fuel lower rates are being quoted.

THE APEDALE EXPLOSION.—The coroner's jury returned the following verdict as the result of their inquiry:—"That the men met their deaths from an explosion caused by a blown-out shot," and they wished the foreman to state that they were strongly of opinion that the management of the colliery had been most lax and negligent, leading, in the opinion of the jury, to the gross carelessness shown by their subordinates. They further decided "That the mine was not a dry and dusty one."

SWANSEA, 29TH APRIL, 1891.

TINPLATES.—The dependence of the tinplate of South Wales on the American market is shown by the resolution of the Tinplate Makers' Association, unanimously passed, to close their works for twenty-eight days from the 28th of June next. This measure was resolved upon in order to enable buyers to dispose of their large accumulated stocks in anticipation of the operation of the McKinley Tariff Act. Some idea of the amount of these stocks may be formed from the fact that the shipments of tinplate from Swansea in the month of March were 22,703 tons, as against a little over 10,000 tons in the corresponding month of last year. The stoppage, which, as regards 298 mills, was definitely agreed upon at the recent meeting, will involve, if made general, a reduction of about one million boxes in stocks. The tinplate makers have, during the recent busy period, been making very large profits, and one maker indeed estimates the total for the last seven months at not less than £1,000,000. They can therefore afford to wait, but the case is different with the steel makers, especially those owning blast furnaces, who have had to pay very high prices for fuel and ore. Messrs. Wright, Butler, & Co. have already put out their two blast furnaces at Carnarvon, and are preparing to do the same with their two furnaces at Landore, finding it cheaper to buy the necessary pig iron. The effect of the month's stoppage on the men must also be deplorable, not only through the loss in wages, which will amount to nearly £150,000, but also because it will aid the development of the tinplate making industry in the United States. Altogether the immediate outlook for the 30,000 hands employed at the 500 mills owned by the trade is not reassuring.

CARDIFF, 29TH APRIL, 1891.

THE IRON AND STEEL TRADE.—A slight improvement is observable in the hematite pig iron trade, and, in addition, makers are finding some relief in rather lower prices for fuel with reduced wages. There is nothing new to report in the steel rail trade. One or two inquiries have come to hand, but transactions have been limited. Quotations for heavy sections range from £4 10s. to £4 15s. Consequent upon the proposed stoppage for a few weeks in the tinplate industry, there is only a small demand for Bessemer steel bars, the price for which, however, has not been changed. In the iron ore trade a few cargoes have changed hands at rather lower prices on account of the low freights, but for quantities prices are maintained at 13s. 3d. to 13. 9d. c.i.f. Cardiff and Newport, 50 per cent. basis. Manganiferous ore finds a better outlet on account of an extra furnace being turned on to spiegel.

COAL AND COKE.—Exports of coal last week reached 288,000 tons, which is very little short of the highest total recorded. With such heavy shipments prices are maintained at the recent level, a fact contrary to the general anticipation, which was evidently based upon the theory that with the depression in the iron, steel, and shipbuilding industries the prices of coal would certainly recede also. It should be remembered that Welsh steam coal finds its way to all quarters of the globe and is used for various purposes, and hence, the dulness pervading kindred industries is unable to effect coal. Colliery property is still eagerly sought after and there seems every prospect of a steady year's trade. Large steam coal is quoted at:—1st quality, 14s. 6d. to 14s. 9d.; 2nd, 13s. 9d. to 14s. 3d.; 3rd, 13s. to 13s. 6d.; 4th, 12s. 6d. to 12s. 9d.; and small steam, at 5s. 3d. to 5s. 6d. The house coal market is easier with prices for No. 3 Rhondda 14s. 6d., and No. 2 Rhondda 13s. The prices of coke are, furnace, 17s. 6d. to 19s.; foundry, 20s. 6d. to 21s. 6d.; best foundry, 23s. to 25s.

BARROW-IN-FURNESS, 29TH APRIL, 1891.

HEMATITE.—There is a rather better tone in the hematite pig iron trade this week, and although the amount of business has not increased there is every reason to expect that it will do so shortly. In the meantime prices are firm at 48s. 6d. per ton for hematite warrants net cash, while makers are asking 49s. 6d. to 51s. 6d. for Bessemer parcels in mixed numbers net f.o.b. There are still 40 furnaces in blast, and 37 are standing idle. The stocks of iron have been decreased this week to the extent of 2,560 tons, leaving the stocks still in hand at 167,417 tons. Further reductions in stocks are likely to take place, as the consumption is maintained at a point a few thousand tons greater than the actual rate of production. The business in forge iron is quiet, but there are better prospects of trade in the Bessemer department by reason of a fuller demand.

STEEL.—The steel trade is very fairly employed, and during the week some good orders have been secured, including a large contract from the Cape Government, by the Barrow Company, and an equally large contract on American account, received by Messrs. Cammel & Co., of Workington. Heavy rails are quoted at £4 12s. 6d. per ton net, but business has been done for large parcels at £4 11s. per ton. There is not much doing in light rails, which are quoted at £5 15s., or in colliery rails, which are at £6 10s. per ton. The trade in steel shipbuilding material is quiet, although makers have still some orders to deliver. This trade depends naturally on the activity of shipbuilding, and it is considered probable that some large orders will soon be placed. In blooms, billets, and tinplate bars the business is comparatively easy, and slabs are quiet, but in hoops there is a steady trade, and there is still plenty of activity in heavy steel forgings.

THE "EMPRESS OF INDIA."—A telegram received from Vancouver, B.C., says that the steamer "Empress of India" arrived there on the 28th inst. from Yokohama. She made the passage in 10 days 14 hours 34 minutes, thus beating all former records between Yokohama and this port by over two days. The "Empress of India" was built at Barrow-in-Furness by the Naval Construction and Armaments Company, Limited, and sailed from the Mersey in the beginning of February with a full complement of passengers for a round-the-world tour. Her maiden trip has been a great success, and her first achievement on the Pacific, which represents a speed of 18 knots an hour, marks a revolution in the passenger service between Canada and Japan and China.

BUSINESS ANNOUNCEMENT.—Mr. Alexander Adamson, formerly shipyard manager of the Naval Construction and Armaments Company, Limited, Barrow-in-Furness, has just been appointed to a seat at the Board of that company, and will occupy the position of managing director of the company in room of the late Mr. A. D. Bryce-Douglas.

MIDDLESBROUGH, 29TH APRIL, 1891.

PIG IRON.—There is little business in pig iron, except in the way of speculation. Warrants are strong at 39s. 2d. sellers, buyers being 39s. cash. West Coast hematite has been sold at 49s., and East Coast is quoted at 51s., but the price is merely nominal. Some makers of pig iron have not sold under 40s. per ton, but the majority would be willing to take 39s. 6d., and even 39s. would be acceptable to some. The stock in Connal's store on the 27th inst. amounted to 118,215 tons, having decreased during the month 4,479 tons. It is expected that there will be a decrease in stocks at the end of the month by at least 5,000 tons.

SHIPMENTS OF PIG IRON.—The shipments to Scotland are larger than ever, but the shipments abroad are just about half what they were this time last year. Those to Scotland up to the 27th inst. amounted to 34,945 tons, against 9,025 last year, but those abroad only amounted to 27,410 tons, against 52,089 last year. The total shipments amounted to 71,013 tons, against 65,744 last year, so that the increased shipments to Scotland have more than made up for the decreased shipments abroad.

MANUFACTURED IRON AND STEEL.—Business is very dull, and works are beginning to be slackly employed. Prices are much the same, but concessions could be got readily. Iron ship plates are £5 12s. 6d.; angles, £5 10s.; and bars, £5 12s. 6d. Steel ship plates are £6 2s. 6d.; angles, £5 17s. 6d.; and rails (heavy section), £4 10s. per ton, all except the last, which are net, being liable to the usual discount of 2½ per cent., and f.o.t. at works.

SHIPBUILDING.—This industry is steady at present, but it is thought that as the year advances it will fall off somewhat. Another shipyard, however, is to be opened on the opposite side of the Tees near to Haverton Hill, and this fact looks promising. There is plenty of work in all the yards at present. There is also another marine engineering works being started in Middlesbrough on the premises of the late Cleveland Bolt and Nut Works.

SUNDERLAND, 29TH APRIL, 1891.

SHIPBUILDING AND ENGINEERING.—Shipbuilders have many inquiries, but these appear to be merely tentative. It is not likely that many orders will be received until quotations fall, and this is dependent upon the labour market. Engineering establishments are beginning to reduce the number of their employés. This industry will locally feel the pending slackness to the greatest extent, as so many sailing vessels are being built. There have been eight vessels, of 17,780 tons, launched during this month, making a total of 25 vessels (of 53,787 tons) for the current year. There are 52 vessels (of 120,945 tons) under construction, as compared with 59 vessels (of 127,552 tons) a year ago. On the 25th inst. there were three steamers launched—viz., the "Venango," for the Neptune Steam Navigation Company, Limited, by Mr. James Laing, Deptford; the "Nerano," for the Pinkney & Sons Steamship Company, by Messrs. Short Bros., Pallion; and the "Wallarah," built to the order of Mr. William Lund, of London, by the Sunderland Shipbuilding Company, Limited. On the 27th inst. Messrs. William Doxford & Sons, Limited, Pallion, launched the s.s. "Clan McIntyre," for the Clan Line of steamships, and the s.s. "Clan McLeod, for the same company, has nearly been completed.

SHIPPING.—The freight market is still unsatisfactory. The improvement effected in homeward rates is being discounted by a fall in outward freights. The lowest point has almost been touched again in the rate from Tyne to Genoa. During the month of March there was again a falling off in the income of the River Wear Commissioners. As compared with March, 1890, the total decrease is £1,643 5s. 9d. This is largely due to the decreased coal shipments, which are 53,623 tons less than for the same period of last year. During last week 69,641 tons of coals were shipped, a decrease of 16,676 tons as compared with the corresponding week last year.

NEWCASTLE, 29TH APRIL, 1891.

THE COAL TRADE.—The Northumberland coal owners have intimated to the miners' representatives their intention to claim a wages reduction of 3¾ per cent., the average selling price of coal having declined 6·22 per cent. during the quarter ending the 31st ult. The shipments of coal and coke at Tyne Dock during the week ending the 25th inst. amounted to 114,497 tons, being an increase as compared with the shipments for the corresponding week last year of 1,303 tons.

SHIPBUILDING.—Several launches have taken place on the Tyne this week, but the vessels have not been replaced by keels for others, a circumstance which indicates an approaching slackness in the yards. The Tyne Shipbuilding Company have been commissioned by a Newcastle firm to build a steamer of large tonnage, and it is rumoured that one or two other orders for vessels are about to be placed. Almost the whole of the graving docks are now occupied, there being a large amount of repairing work to be done. At many of the shipbuilding establishments advantage is being taken of the present lull in business to make necessary changes in the plant and general working arrangements.

ENGINEERING.—Marine engine shops continue to be fairly busy, though few new orders are being received. Messrs. John Abbott & Co. have many orders on hand for hydraulic machinery to be shipped to New Zealand and Australia, and the whole of their departments are kept well employed. Messrs. Watson & Sons, of the High Bridge Works, have secured a portion of the order for the requirements of the current year in gun-metal articles at the Government dockyards. The firm are also carrying out many orders for gun-metal accessories required in the equipment of war vessels which are being built by private firms. Messrs. Hawthorn, Leslie, & Co.'s branch engineering establishment at Forth Banks is at present somewhat slack, as no new contracts have been secured. The St. Peter's Works of the firm are, however, exceedingly busy.

TRADE DISPUTES.—The engineers employed at the works of Messrs. Palmer & Co., Jarrow, have come out on strike, owing to an alleged appropriation by the plumbers of certain work which the engineers claim should be done by themselves exclusively. These disputes regarding the apportionment of work are recurring very frequently, and, unless some method is found of putting a stop to them, they will cause much trouble in the future. The smiths at Messrs. Stephenson's Hepburn works and the chainmakers at Messrs. Abbott's works, Gateshead, have disputes with their employers with reference to the prices paid for piecework.

THE LATE MR. JOHN WALKER.—On the 24th inst. Mr. John Walker, general manager of the North British Railway, died suddenly in London. Mr. Walker was at first in the service of the Edinburgh, Perth, and Dundee Railway Company, and on the amalgamation of that company with the North British Railway he was transferred to the head office. Some years afterwards he was appointed secretary to the North British Company, and he held that office till about 1872, when he was elected a director. He continued on the board till 1874, when he was appointed general manager of the company in succession to the late Mr. Mason.

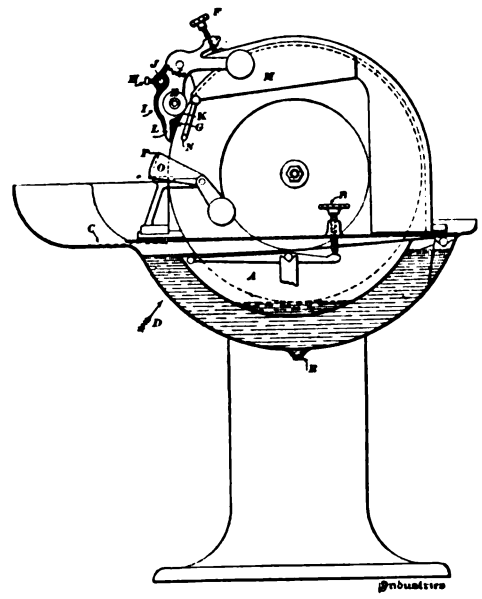

Fig. 2.

THE NICARAGUA CANAL.

III.

(*Continued from page* 363.)

PROPOSED ROUTE.

The central section of the canal, from Ochoa to Lake Nicaragua, follows the River San Juan, and has a length of 64·54 miles. For this little excavation is required, but to make it navigable a dam is to be constructed at Ochoa, which will have the effect of flooding the valley of the river for a great proportion of its length and maintaining the water at a level of 106ft. above the sea. The dam will abut against two steep hills, have an average height of 61ft. above the river bed, a width of 25ft. at the top, and 500ft. at the base. The length of the weir crest is fixed at 1,250ft., and that of the abutments at 650ft. It is estimated that, with a mean flow of 20,000 cubic feet per second in the river, the depth of water above the weir will be about 3½ft. Between the Toro Rapids—indicated on the plan Fig. 4 on page 362—and the lake, a distance of 28 miles, blasting under water and dredging will be necessary in several places to an average depth of 4½ft., equivalent to about 24 miles in length. Below the rapids the width of the navigable channel will nowhere be less than 1,000ft., with depths ranging from 28ft. to 130ft. The average minimum depth of the water, as raised by the dam, in the shallowest places is to be 23ft. The Ochoa dam it is proposed to construct in the same manner as those previously mentioned—namely, of "rock fill" and earth backing. As described in Mr. Menocal's report, "the core of the rock portion will be made of smaller stones, gravel, and refuse from the rock cuts, with three rows of sheet piling from abutment to abutment, and substantial concrete core walls from the ends of the sheet piling carried well into the abutment hills and up along the slope beyond the maximum flood level. The upper portion and long flat apron will be composed of stones of the largest dimensions that can be handled and arranged, the interstices being filled from behind with small stones, gravel, and earth dumped from suitable trestles."

A short distance above the site of the Ochoa dam is the confluence of the San Carlos with the San Juan River. To the east of the former river is a ridge running in a direction south by west, but this ridge is interrupted by gaps which at certain points are below the water level. Such gaps will be closed by embankments, the top of the latter having a height of 112ft. above the sea level. In the ridge in question it is intended also to provide a large waste weir, which will discharge the flood waters of the San Carlos into the San Juan River below the Ochoa dam, where a natural channel exists in the Cureño Creek. Across Lake Nicaragua itself the distance to be traversed by vessels will be 56·5 miles. From the mouth of the canal on the east side of the lake it will be necessary to dredge for a distance of about 14 miles in soft mud in order to maintain a depth of 30ft., but the average depth of the artificial channel required is only 9·8ft., with a width of 150ft. at the bottom, the sides having a slope of 3 to 1. No further excavation in the lake is necessary from the end of this channel to within 1,400ft. of the west shore, but here a cutting has to be constructed in rock. It is considered advisable to provide for the building of two breakwaters at the entrance of the canal on the west shore of the lake, one on either side, for the purpose of protection against prevailing winds, of arresting débris drifting along the coast, and of serving as guides to approaching vessels.

We now come to the western division, extending from Lake Nicaragua to the Pacific port of Brito, and having a length of 17·04 miles. Of this distance, 11·44 miles will have to be excavated entirely, while the remainder, 5·60 miles, passes through the Tola Basin, situated in the valleys of the Grande and Tola Rivers. Like the other basins in the course of the canal, the Tola Basin will be formed by the erection of a dam. From its estuary on Lake Nicaragua the projected channel follows the valley of the Lajas River for 8,260ft. Here the river turns southward, while the canal continues its course in the same straight line, and at 4·7 miles from the lake crosses the "Western Divide," which has an elevation of 152ft. above the mean tide in the Pacific. Descending at the rate of about 9ft. per mile, in 1¾ miles it meets the Rio Grande, and follows generally for some distance the course of this mountain stream, cutting through some of its sharp bends. Nine miles from the lake the basin of the Tola is reached. The embankment by which the basin is formed is to have a length of 1,800ft., and a height of 70ft., and its structure will be exactly similar to that of the Ochoa dam. The top of the embankment will be 112ft. above sea level, so that the level of Lake Nicaragua will be extended through the divide and the basin to the embankment. The estimated area of the Tola Basin is 4,000 acres, and for over 4½ miles its depth will range from not less than 30ft. to 70ft. The rock excavated in forming Locks 4 and 5 will be utilised in the construction of the embankment, as well as the earth removed in constructing the canal to the east of the basin. A weir, 1,300ft. long, and the lock culverts are relied on for controlling the lake level, even during exceptional floods, but to make assurance doubly sure it is proposed to construct a "guard gate" in the canal between the lake and the "Divide," by means of which, on an emergency, the water can be shut off from the former. Westward of Locks 4 and 5 the canal will flow through a broad flat district to the port of Brito. 1·58 miles below Lock 5 is the sixth and last lock, between which and Brito the canal will be at the sea level.

Greytown Harbour Improvements. — An essential preliminary to the construction of the canal is the improvement of Greytown Harbour, with which considerable progress has already been made. Between the inner bay, on the shore of which Greytown is situated, and the sea, there existed thirty years ago a narrow but safe channel, through which the largest vessels could pass. The action of the waves has, however, thrown up a sand bank, closing the entrance to this channel, so that at present—or at any rate previous to the commencement of the works now in progress—the bay is converted into a fresh water lagoon. The plan adopted for restoring the harbour consists, first, in the construction of a breakwater nearly at right angles to the shore of the sand bank referred to, having a length of about 2,000ft. and extending to a depth of six fathoms; and, secondly, in dredging from this depth through the sand bank into the inner bay. As the shifting sand arrested by the breakwater begins to silt up the new entrance, the breakwater will be extended, the process being repeated until a new coast line is formed perpendicular to the direction of the prevailing wind. The new entrance channel will have a depth of 30ft., and a width at the bottom of 500ft. To a depth of 15ft. of water the jetty will be constructed of creosoted timber, fascinage, and stone; beyond this, in deep water, of rubble, the stone for which will be furnished from the excavation of the "Eastern Divide."

The inner basin of the harbour will have an excavated area of 206 acres, which, with the enlarged section of the canal as far as Lock No. 1, gives a total area of 341 acres of water, 28ft. deep, exclusive of the slopes of 2 to 1, and the natural accommodation afforded by the rest of the bay, which is sufficient for a considerable number of vessels of ordinary size.

Brito Harbour.—At Brito also harbour improvements are required. The main portion of the harbour will have to be excavated in the alluvial valley of the Rio Grande, which here debouches on the coast, but a part of it will also be in deep water protected by two breakwaters, one 900ft. long, projecting from the shore at the western extremity of the range of hills which extends along the Pacific coast, the other 830ft. long, normal to the beach on the opposite side of the basin, as indicated in Fig. 5 in our issue of the 17th ult. The new harbour will penetrate about 3,000ft. inland from the present shore line, while its whole length, measured from the entrance between the breakwaters, will be 3,900ft. In addition to this, the canal itself, being here constructed of enlarged section as compared with its average dimensions, will form an extension of the harbour for another 3,000ft. The total harbour area, including the wider portion of the canal itself, will be about 103 acres, with a depth of 30ft.

(*To be continued.*)

NEW TOOL GRINDER.

The accompanying illustrations, Figs. 1 and 2, represent a general view and side elevation of a new tool grinder, made bythe Leland, Faulconer, & Norton Company, Detroit, Michigan, U.S.A., which is of novel construction. A wheel is carried at each end of the spindle, and the two wheels are so arranged that they may be removed from or put on the spindle with little trouble, and without disturbing the spindle or boxes.

The front of the water pan is in the form of two part circles, so that no matter where the operator stands he will be about the same distance from the wheel. There are guards, which effectually prevent the throwing of water about the machine. They are adjustable to the wheels, and held in position by bronze bolts, so that there is no trouble from rust when they are to be moved. Upon the rest is pivoted the guard *O*, which is counterbalanced, so that when not in use it rises above the rest; but when the tool is placed upon the guard at *P* it descends until the tool bears upon the rest, in either position doing much to prevent throwing of water, while at the same time it also prevents sudden gouging of the wheel. Provision is made for keeping the wheels true, and in the best possible condition for effective work, by the adjusting device seen attached to the wheel guard above the rest. This consists of a threaded roll of steel running upon a hardened and ground arbor in bronze bearings, and brought into contact with the wheel by turning the small hand-wheel *F*. It is intended to be used in keeping the wheel true whilst running rather than remedying its defects. The surface *G* is of chilled iron, and is held to the stone by gravity only, so that it does not bear hard upon it. For a water supply no pumps, valves, or other similar devices are made use of, yet the supply is under perfect control by simply turning the hand-wheel *B*, which, as will be seen, is on a screw, which bears upon one end of a lever, which is fulcrumed as shown, and supports the front end of the tank *A*, the other end being pivoted at the back, as shown.

The wheel spindle is of crucible steel, ground accurately to size with the collars turned all over, to ensure exact balance, and has bearings 2⅛in. diameter, 8in. long. The wheels are 24in. diameter, 1½in. face, and are 25½in. apart.

We are indebted to our esteemed contemporary the *American Machinist* for the illustrations.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 76, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 1ST MAY, 1891.

MR. GOSCHEN'S BUDGET.

THE Budget speeches of Mr. Goschen are received annually with scarcely less public interest than were those of Mr. Gladstone during the best period of his career as a public financier. The reputation of Mr. Goschen has relieved him of the burden of the carping criticism which is generally directed against the statements of less famous Chancellors; but it has also militated to some extent against adequate examination of his financial proposals. His authority as a practical financier on a considerable scale has, indeed, helped to obscure some of the less sound of his devices, and has helped to reconcile the public mind to many fresh departures which, if they had been proposed by lesser men, might have been universally reprobated. Again, he has had the good fortune to occupy the position of Chancellor of the Exchequer during a period of prosperity which followed a period of unexampled depression. In his recitals of the results of the finance of the past years he has thus always been in the agreeable position of being able to congratulate himself and the country upon a revenue which had expanded at a rate greater than his estimates, and upon an expenditure which had fallen short of these. On the present occasion he has been equally fortunate, although there is an unpleasant reservation that if the whole of the expenditure of the year had been debited in the accounts of the year, so agreeable a result could not have been reached. Mr. Goschen is, of course, not without the excuse that such a state of matters is not unknown in previous Budgets, and that the records of both parties are not without examples of similar expedients whenever occasion arose that seemed to demand their adoption. More serious, however, in the finances of the past year, is the discovery that some of the spending Departments have asked for much more money than they have spent during the year. It is well, certainly, that departmental estimates should make a complete disclosure of projected expenditure; but there is something seriously wrong when rather more than a million of money is taken from the pockets of the taxpayer, and therefore from the resources available for industrial purposes, in excess of the amount actually required by the spending Departments. Either gross blunders must have been made in the estimates, in which case the permanent officials are to blame, or Mr. Goschen has succeeded in compelling the spending Departments to reduce their expenditure by an amount so large as to suggest gross extravagance in the past. It is also open to question whether the reduction in expenditure has not been accomplished, to some extent, at least, at the expense of efficiency. The details which Mr. Goschen gave of the industry of the year were at once valuable and encouraging. The great and sudden increase of the profits from several important industries is a noticeable feature in a year which has been characterised by considerable financial disturbance, by not a few serious strikes, and by a general feeling of uneasiness as to the immediate future. The long-delayed return of prosperity to the cotton trade will be noticed with satisfaction. The increase in the earnings of a set of collieries between 1887 and 1889 is, however, so large as to suggest that these collieries have been exceptionally fortunate. It can hardly be supposed that an increase in profits in three years of 300 per cent. was universal throughout the kingdom. Basing his estimate for the coming year upon considerations suggested by these figures, Mr. Goschen regards an increase in the revenue of the year of £1,200,000 as a fair expectation. He estimates the total revenue at £90,430,000, and the expenditure at £88,440,000. The estimated surplus is thus nearly two millions. Mr. Goschen's plan for dealing with this surplus must come before Parliament in another form, and from a certain section of the people is not unlikely to receive strenuous opposition. He proposes to devote one-half of the surplus to the payment of the increased charge upon the Exchequer that will be entailed should the Government succeed in passing a measure for the granting of "free" education to England. The remainder of the surplus he devotes to the extent of £500,000 to the erection of barracks, and to the extent of £400,000 to the withdrawal of light gold coin now in circulation. As regards the last of these proposals, it would have been interesting—indeed, highly advisable—to know how much of the £600,000 granted last year for this operation has been expended, and also whether it is to be supposed that the sum now asked for will suffice to complete it. As regards the destination of the bulk of the surplus, and apart altogether from party politics, which are inadmissible in these columns, it may be doubted whether there is any real demand for free education at the moment. It is not very clear whether the addition of a sum of £2,000,000 a-year, proposed for the future needs under this head, will suffice to make education free, even so far as it is compulsory. There will thus be a tendency either to cheapen the cost of education, which is already being done in Scotland, where fees have practically been abolished, or there must be a considerable addition to local rates. The Government, no doubt, feels itself committed to legislate in this direction. Meanwhile it may be well to note that our national Budget is gradually creeping up to a hundred millions a year. Although in times of prosperity taxpayers may accept the inevitable and forbear to grumble, a time of depression may come when even the present burden may become excessive. Moreover, there is at least one highly uncertain item in the annual receipts to which Chancellors of the Exchequer have hitherto always looked for support—that is, the revenue from spirits. The revenue from this source has almost always been in excess of the estimates; but no possible assurance can be given that it will continue to be so. It is, indeed, a most uncertain source of revenue, and is liable to fall away all the more seriously during a period of depression as it increases more rapidly during a period of prosperity. One item in Mr. Goschen's statement is questionable enough to have already led to much criticism. This is his proposal to set apart the dividends which, after the year 1894, will accrue from the Suez Canal shares, in order to provide for an addition to our national defences. The provision of national defences is a matter by itself, and there is no more special need for setting apart the dividends on the Canal shares, than there is for setting apart the duty on snuff or a farthing of the sixth penny of the income-tax. The device is, indeed, like the childish one of wrapping in special parcels the money intended to be devoted to separate uses.

Digitized by Google

The argument, too, that the taxpayer is not called upon to provide this annual sum of £600,000 because it is derived from the Suez Canal is a mere subterfuge. It is impossible by any method of financing to get over the circumstance that there are but two sides to the taxpayer's ledger—viz., debit and credit—and that, whatever appears on one side is paid out, and whatever appears on the other side is received. Besides, it is entirely beyond the power of Mr. Goschen to limit the range of choice as to the disposal of national funds of the Chancellors of the Exchequer and the Parliaments of the future. Even sinking funds have not escaped the exigencies of changes in Administrations, and there have been cases in which Ministers have suspended sinking funds of their own creation. Some surprise has naturally been felt that Mr. Goschen made no reference to the proposals as to the gold reserves and to the issue of £1 and 10s. notes made in his speech at Leeds in January last. Perhaps the hint that the currency proposals hung on the question of light gold may be taken to mean that when the motion on the withdrawal of light gold is made he will refer to them. It may be that Mr. Goschen is meeting with unforeseen difficulties in perfecting his plan, either through the obstinate attitude of the banks, or through difficulties inherent in the nature of his proposals. It is interesting to note in this connection two points in Mr. Goschen's speech—first, that bankers have been reaping during the three past years a very heavy increase of profits, and that the amount passed through the bankers' clearing houses has enormously increased. This constitutes an argument in favour of causing the banks to defray the cost of the new gold reserve since they enjoy privileges so extensive and profitable. The second point is that the profit on silver, due to the difference between the price of silver in the market and the face value of coined silver, has brought in £200,000 over the amount received on this account in the previous year, and that the demand for silver is increasing rapidly. This increased demand for silver may probably be set down to an increase in wages, and suggests also that the present is a favourable moment for the passing into circulation of 10s. notes based on silver. The cost of coinage would be saved, and the trouble of circulating the silver, and subsequently withdrawing it or withdrawing half sovereigns, might be avoided by promptly placing the 10s. note within reach of those who require to use small change.

The Budget, if it be taken as a whole, may be set down as colourless: it neither increases nor remits taxation, although it shows a surplus of a couple of millions. Its leading feature, the provision in anticipation of funds for granting free education, certainly wears the aspect in which it seems to have been generally regarded in the country—namely, that of a Dissolution Budget, in which the Government, feeling certain of the support of the upper and middle classes, makes a bold bid for the support of the masses. Whether the Government is offering them a boon which they do not want, or do not care to have, remains to be seen. It is probable that if they had been consulted they would have voted by preference for a reduction in the duties upon tea, coffee, or tobacco.

FLASHING SIGNALS IN THE NAVY.

The Parliamentary paper which was recently issued, giving the whole of the official correspondence relating to Rear-Admiral Colomb's system of flashing signals, is interesting from several points of view. It gives a fairly good account of the services of a highly distinguished naval officer, and also enlightens the public on some of the official methods of looking at things. The student of the history of scientific inventions will, on reading the correspondence, be struck with an illustration of the fact that no one man is the sole inventor of any mechanical or physical arrangement. Most discoveries or inventions have been evolved from the conditions of the times or the environment of the nominal inventor, who very often seized on the speculations or imperfectly developed designs of some previous workers. Some time since we received a pamphlet written by Major-General Babbage, son of the late Charles Babbage, which was written for the purpose of showing that the latter was the real inventor of the occulting system of telegraphing known in the army as the heliograph, and in the navy as "Colomb's signals." The writer showed that his father, as early as 1851, published a description of the system in his work entitled "The Exposition of 1851." At pages 103 and 111 he gave full details of his system of telegraphing by occultation for use in fleets and lighthouses. He made many experiments, and expended not a little money, in perfecting it, and during 1851 he exhibited an occulting light at a window in his own house in London, which attracted attention, and was seen by many. The pamphlet was published on the occasion of a deputation to the First Lord of the Admiralty urging the claims of Admiral Colomb for some form of recognition as the inventor of the flashing systems of night and fog signals, and the writer urges that if the Government thinks fit to recognise the usefulness of the invention and the claim of the inventor, its liberality should be extended to the representatives of Charles Babbage, both as a recognition of his scientific claims, and of his services in the matter. Admiral Colomb's patent is dated May, 1862, and there cannot be the slightest doubt that the method has been much improved by his exertions. Although we cannot enter into a discussion of the relative claims of Babbage and Colomb, we think it is only right that the work of the former should not be overlooked, while that of the latter has at least received the honour of being recorded in a continuous form in a Parliamentary paper. Babbage's life, and a great part of his fortune, was spent in attempts to work out various mechanical problems, and although the results may not have been of much practical utility, still they are worthy of recognition, not only on account of their value to science, but also because of his unselfish devotion and unwearied perseverance to objects beyond the sphere of ordinary occupations.

The correspondence which has been published shows that Admiral Colomb has for twenty years been seeking for what he considers a proper recognition of his claims, and, like many ingenious men, he has been kept all that time in a state of suspense. Early in his career he received a gratuity of £500, and before payment the Treasury wished to be assured that no further claims could be with justice made for similar remuneration in connection with the invention. After considerable correspondence a receipt was given by Captain Colomb, which seems definite enough, as it is "in final and absolute discharge of all claims on Her Majesty's Government on account of signal arrangements for land service, and in respect of signals for joint naval and military use," but Admiral Colomb states that the form of receipt signed was specially prepared in order to leave his naval claims open. Almost immediately after the payment the flashing system was fully adopted and introduced into every ship in the service. In 1876, when he was serving as flag captain on the "Audacious" in the China seas, he presented a petition to the Government, proposing that his claims for recompense should be referred to arbitration. He expressed the opinion that there never had been in the modern navy so considerable a service so ill-requited as his had been. For, instead of being rewarded, after excessive labour in maturing the invention, and after still more excessive labour and anxiety in obtaining its adoption by the Navy—after complete success in both efforts he found himself a poorer man than if he had never made them; behind in his profession, and with no prospect before him except a compulsory retirement from the service which he had benefited. His application was supported by Admiral Ryder, who expressed the opinion that the former award was utterly insignificant, and could only be considered as a small instalment paid while the invention was still in its infancy. He thought that impartial arbitrators would not offer him less than £10,000, although he said he had reason to believe that Captain Colomb would be satisfied with a payment of £5,000. He pointed out the great value of the system of flashing signals, and the high services rendered by Captain Colomb. Both the Admiralty and the Treasury, however, fell back on the receipt which had formerly been given, but, looking at the great development of the system of signalling which had taken place, the Admiralty proposed to the Treasury that Captain Colomb should be paid a further sum of £1,000 on account of his system of signals, and £250 for services in connection with the compilation of a manual to the general signal books. To this proposal the Treasury declined to agree, holding that the previous receipt barred all further consideration of the matter. No further progress was made until May, 1886, when Captain Colomb was compulsorily retired from the Navy and became free to take steps which he could not take while a serving officer. We cannot enter into details here, but may briefly state that in November last the Admiralty proposed to pay Admiral Colomb a further grant of £2,000 on account of his flashing signals, which he, in a very lengthy reply, giving a *résumé* of the whole subject, declined, and there the matter at present rests, although the Admiralty made a special disclaimer of any intention to undervalue either his services or the merits of his invention. It seems to us, however, that by making this last offer the Admiralty admitted the whole principle for which Admiral Colomb has been contending—namely, that some further recognition of his services was necessary. Having done this, we think that it is a comparatively simple matter to arrive at a decision as to what a fair amount should be. Possibly both the Admiralty and the Treasury felt that if they were liberal with Admiral Colomb many other claims would be made. In any further discussion on this matter, we hope that the claims of the family of Charles Babbage will not be overlooked.

THE PIG IRON WARRANTS BILL.

The second reading of the Pig Iron Warrants Bill has been postponed till the 8th inst., but, considering the fact that no fewer than ten notices of motion for its rejection stand in the order book of the House of Commons, by members who represent all parties, its chances of passing are very small. The members of the pig iron "ring" are up in arms against it, but, of course, that in itself does not prove that the Bill is bad, although it may affect their methods of doing business. The other day they were represented by a deputation, which waited on the First Lord of the Treasury and the Attorney-General, and urged that, while the professed objects of the Bill were to put down gambling speculations, its results would really be to shake the pig iron trade to its foundations, and possibly destroy the supremacy of Glasgow as its central market. We think this latter argument should have been omitted. The business of Parliament is to endeavour to allow justice to be done, without regard to the conveniences or even the interests of a very small body of men who have managed to get things pretty well into their own hands. The Attorney-General stated that he understood that the Bill was not intended to interfere with such contracts as were in ordinary use in the trade, and that if it was found that the provisions of the measure would affect such interests the Government would oppose the Bill. On the other hand, the supporters of the Bill are doing all they can to advance its progress. They have issued a statement of their views, and their answer to some of the objections which have been raised against the Bill. They state that it does not call in question the utility of warrant stores or the validity of warrants. On the contrary, it recognises the value of warrants as documents representing pig iron deposited in a public store to be delivered at any time to the holder or presenter of the warrant. The Bill is intended to prevent and to render illegal fictitious and illusory purchases, and sales of warrants where no warrants exist—what is aimed at being the pretence or practice of selling warrants which the individual who sells has not in his possession or under his control. The Bill, in their opinion, will not hinder or interfere with genuine transactions. It will not prevent contracts for future delivery of iron, neither will it prevent a consumer or buyer of iron from obtaining from a maker or merchant a binding tender or contract to supply a quantity of iron on agreed conditions. Its promoters say that the Bill is intended to encourage and facilitate genuine transactions, and to prohibit mere speculative dealings, which dealings are ostensibly in warrants, but are really gambling for differences in value. They think the sound and legitimate trade of the country is injured thereby, and the wages of the industrial classes are subjected to needless fluctuations. This is a very important subject, and it is well that it should be looked at in all its aspects.

THE PANAMA CANAL.

In view of the articles which are appearing in our columns on the Nicaragua Canal, and of the progress which is being made by that undertaking, it is well not to allow the older undertaking of Panama to be entirely lost sight of, for its completion would, of course, have a most important bearing on the other. We have often expressed our own opinions on the subject, but it is so difficult to obtain exact information regarding this great project that it is well to give careful consideration to all opinions which appear to be trustworthy, or at least deserving of attention. M. Lucien Bonaparte-Wyse has forwarded a report on the Panama Canal, and the prospects of its completion, to the official liquidator of the old company, and this will be found more encouraging reading to those interested in the concern than some of the others which have preceded it. He certainly has gone about his work in a most exhaustive manner, and with every appearance of wishing to be impartial. He gives a detailed account of the negotiations connected

Digitized by Google

with the prolongation of the contract, but into these we need not enter. It is sufficient to note that in December last the new contract was ratified by the Columbian Government, and M. Bonaparte-Wyse hopes that this will hasten the advent of the day when the good name of France will have its revenge, and when the narrow but formidable barrier separating the Atlantic and the Pacific will be removed for the benefit of international trade. Referring to the technical and practical aspects of the work, the opinions of the engineers are quoted to the effect that the excavation could be completed in five, or at the most six, years' time. From his own observations on the spot, the author of the report again recommends the formation of a central artificial lake, approached on either side by conjoined locks with double chambers, and then discusses a great many other details connected with the work. The capital necessary for the completion of the undertaking is roughly estimated at 600,000,000fr., or £24,000,000 sterling. He hints that there may be pleasant surprises in store for those who still believe in the completion of the canal, which, in his opinion, is not so impossible as many continue to think, and he expresses the hope that it will be carried out by French hands alone.

THE LATE MR. JOHN WALKER.

The sudden death of Mr. John Walker, general manager of the North British Railway Company, has removed one of the most remarkable figures in the world of railway administration. Mr. Walker had been in London attending the House of Commons Committee which was sitting to consider the railway Bills projected by his company. On Friday last he had left the committee room with the intention of going to Ventnor till Monday. On the way to the station he became ill, and almost immediately after reaching the Waterloo Station of the London and South-Western Railway he expired in the waiting room of the station, the cause of death being an apoplectic stroke. Mr. Walker, who, when he died, was in his sixty-second year, began his connection with the North British Railway in 1862, on the amalgamation between that company and the Edinburgh, Perth, and Dundee Railway Company, in whose service Mr. Walker had spent his earlier years. Since 1874 Mr. Walker had been practical dictator of the company, for in that year he became general manager. Some years previously the company had passed through a serious crisis, having been rescued from bankruptcy by the strenuous efforts of a committee mainly composed of Glasgow gentlemen, led by the late Mr. James White, of Overtown. After this crisis had passed away Mr. Walker conceived the most ambitious designs for the future of his company, and it was mainly through his far-seeing sagacity and boldness that the company secured a practical monopoly of the coal districts in the East of Scotland and paramount control of the great route to the North. The Tay Bridge and the Forth Bridge were integral parts of his extensive schemes, and the initiation of these remarkable enterprises, as well as the large measure of financial success which they have already attained, is due for the most part to Mr. Walker. The past fifteen months have been very eventful for the North British Railway. They have seen the opening of the Forth Bridge, and its connecting lines to the north and the south of the Forth; the consequent enormous increase of traffic, the congestion of the Waverley Station and its proved incapacity for the service of the railway; the promotion of Bills in Parliament for the acquisition of an extended area for the station and its approaches; the unsuccessful Parliamentary campaign for the acquisition of the Glasgow and South-Western Railway; the opposition to the Caledonian Railway Bills for access to Edinburgh; the great strike which lasted five weeks, and cost the company upwards of a quarter of a million, involving the total loss of half a year's income to the ordinary shareholders; and, lastly, the extensive schemes for securing access to the mineral districts of Lanarkshire now before Parliament. All these events crowded into so short a time, and all of them due in a greater or lesser degree to the activity of Mr. Walker, afford evidence enough of the immense grasp of his administrative powers; but they involved a strain which has as evidently broken down an iron physique. It cannot be said that the strain of any one of these events actually hastened Mr. Walker's end, but the burden of them all, involving as some of them did successive disappointments, was fatal. The effect upon the future of the company is hard to foresee. For some years Mr. Walker has in the eyes of the trading community represented the North British Railway, and it is impossible as yet to say what changes may be rendered necessary in the policy of the company by the removal of the master mind that controlled it. Since Hudson, the English, and Hodgson, the Scottish Railway King, no single figure in railway history has stood out so prominently as that of Mr. Walker. Alike for his most single-minded loyalty to the interests of his company, and for his enthusiasm for the development of the mineral resources of Scotland, Mr. Walker will be remembered as one of the most remarkable railway men of his time.

Letters to the Editor.

ENGINEERS IN THE ROYAL NAVY.

To the Editor of "Industries."

Sir,—Your correspondent, "M.I.N.A.," who—I presume I am justified from his remarks in saying—has never served in the Navy, describes himself as "a marine engineer who is acquainted with the requirements both of the Navy and the mercantile marine," and goes on to controvert my statement.

I was very careful, never having served in the mercantile marine, not to claim full knowledge of its requirements, merely stating what my conception of it was — which statement "M.I.N.A." does not controvert—and with all due deference to "M.I.N.A.'s" description of himself, I submit that he is not acquainted with the requirements of the Royal Navy.

If "M.I.N.A.'s" remarks as to artificers, &c., refer to an ideal service in which the able seamen become captains and admirals, then I quite agree that the engineer officers may be drawn from the artificers, and perhaps also the surgeons from the sick berth attendants; into the desirability or otherwise of such an arrangement I decline to enter. But if "M.I.N.A." refers, as I did, to the naval service as at present constituted, and maintains, as I understood your article to recommend, that the ordinary workman should be the source for supplying *any appreciable number* of engineer officers to the Navy, then he does not understand naval requirements.

"M.I.N.A." introduces Mr. Bryce-Douglas's name, which I fully expected would be done. Might I suggest that Mr. Douglas commenced his career *thirty years ago*, a very palpable fact, but one which I fancy "M.I.N.A." and others have not fully grasped the meaning of. As to whether Mr. Douglas would have made a good naval engineer, I can only say that, in my opinion, he would very probably have left the service had he ever joined it.

With regard to "M.I.N.A.'s" last paragraph, does it not seem that, when the best men leave a service and young engineers will not join it, the proper remedy is to improve the conditions of that service, not to lower the qualifications required for joining it? That, at any rate, is how it appears to,

Yours, &c.,
A. E.

Portsmouth, 28th April, 1891.

THE SINKING OF THE "BLANCO ENCALADA."

To the Editor of "Industries."

Sir,—The numerous friends in this country of the Revolutionary Forces in Chili will have learned with profound regret of the loss of the ironclad "Blanco Encalada," which was blown up by a Whitehead torpedo discharged from the Government cruiser, "Almirante Lynch," in the Bay of Caldera, on the 23rd inst.

The "Blanco Encalada" was a sea-going ironclad, of about 3,500 tons, of the central battery type, designed by Sir Edward Reed, and built in Hull. After taking an important part, in company with her consort and sister ship the "Almirante Cochrane," in the late war with Peru, she returned to England in 1885 to be completely overhauled and re-armed at Elswick, taking up her station again on the South Pacific in 1887. Her new armament consisted of Armstrong breechloading guns, Hotchkiss and Nordenfelt rapid-firing guns, Whitehead torpedoes, and all the equipment of a modern ironclad. Her speed before alterations was about 10 knots, and it might probably have been increased to 12 knots. Her adversaries, the "Almirante Condell" and the "Almirante Lynch," belong to a type of vessels the immense value of which has been only too tardily recognised by our own Admiralty—torpedo cruisers of very high speed, lightly armoured, but heavily armed with rapid-firing artillery and self-acting torpedoes. These two vessels, recently built in England, set out from Valparaiso, commanded by an experienced officer, Captain Moraga, and, sailing into the Bay of Caldera, surprised the "Blanco Encalada," and struck her with a lucky (!) or unlucky torpedo, destroying the ironclad.

It appears that the "Blanco Encalada" was lying at anchor, and that the attack took place in the early morning, at a time when, by the routine of a Chilian man-of-war, it would be most fatal, one experienced officer only being on deck, while the crew would be occupied in the peaceful operations of scouring brass and holystoning. Quartermasters are often sleepy in the morning, and probably the officer may have been preoccupied in his chartroom, little expecting that two of the latest and most perfect machines of destruction produced by the naval genius of England were appearing as enemies over the horizon. Once well in view, all hope for the ironclad, moored and unprotected as she appears to have been, was lost. The two torpedo boats circled into the bay, and it is said that seven torpedoes were discharged, one of them sinking the vessel.

Torpedo warfare has probably been more extensively and more fatally practised on the West Coast of South America than anywhere else; and the Chilians and Peruvians have both proved themselves to possess, at least in attack, all the vigilance, resource, and ingenuity upon which these operations are dependent. So far as our present information goes, however, this latest incident seems to indicate nothing new excepting negligence on the part of the officers in having the ship at anchor and unprotected in the present state of affairs—if she were at all able to steam. There can be little doubt that if the vessel had been at sea, and could have chosen a duelling ground with the two cruisers, we should have had news of another tenour. Opposed to an ironclad thoroughly armed with Hotchkiss and Nordenfelt guns, and a powerful battery of artillery worked by hydraulic power, and directed and controlled by electricity, the "Almirante Lynch" and "Almirante Condell" would have required even more than the heroism of the names they bear before they could have achieved such a feat as the sinking of the "Blanco Encalada."

It would be a great mistake for speculators and others in this country to assume that by the loss of this ship the Revolutionary Forces in Chili have received a death blow. On the contrary, we may be perfectly certain that there will now be war to the knife, and that unless the Government of the autocratic President sees its way to submit themselves to the judgement of their country they will eventually have to capitulate before superior resources. There still remains with the Chilian revolutionary fleet the sister ship to the "Blanco Encalada," even more modern than the latter vessel, also a number of well-armed corvettes and—most significant of all—the protected cruiser "Esmeralda," which, swift and powerfully armed as she is, could give a very good account of any of her enemies before they could come within effective torpedo range.

There can be little doubt that we should have heard ere now of stirring incidents in connection with this ship had she not apparently been detailed off for some special service. The nature of this we can only speculate, but I have little doubt that she has gone to the Straits of Magellan to await the arrival of the new cruisers from Europe which are on their way out to succour the Government. The issue may be another practical and deadly experiment in modern naval warfare unless—and this is equally probable—the two cruisers are escorted up the coast as new allies for the revolution. In any event I think that those who know Chili best will agree with me that from the fact that the greater part of the youth, energy, and enthusiasm of the country is on the side of the revolutionists, the Government of the day will sooner or later be obliged to capitulate.

I am personally acquainted, and have been a messmate of a number of the officers whose names are now appearing in the Chilian despatches. The leaders of the naval forces, or nearly all of them, are exceedingly able and experienced sailors, and not a few have gained their experience under our own flag. The best of them are men keenly interested in South American progress, and with European ideas and European experiences. With the control of a powerful fleet it is not surprising that they resist the attempts of an unscrupulous adventurer to demoralise and override the institutions of their country.

Yours, &c.,
Alfred E. Mayor.

32, Victoria Street, London, S.W.,
30th April, 1891.

TUCKER *v.* KAYE.

To the Editor of "Industries."

Sir,—I have seen your reports of "Tucker *v.* Kaye" in your issues of the 27th ult. and the 18th inst., and I conclude from your remarks that you have by some means got a wrong impression, which I hope, in fairness to Mr. Justice Romer and myself, you will allow me to dispel.

You did not state in your report that I had a patent, but I may state that we had been making my patent automatic railway wedge lock for some time, when I got a letter from Mr. Tucker's solicitors, charging me with infringement of Tucker's patent. I got Tucker's specification, and, on examining his patent, I found that the only part which I had in my lock which Tucker had in his was old, and I had not claimed it—my firm, and also many others, having made it before Tucker's patent. I wrote Mr. Tucker, stating that I was not infringing his patent, and his solicitors replied, saying that they had received my admissions, and they issued the writ. I also sent the specifications to Lord Grimthorpe for his lordship's opinion, who wrote me, showing Tucker was wrong, as he had pointed out Tucker's principle in his book on "Clocks and Locks," about the year 1846.

You seem to think there is a value in Tucker's lock on account of having no projection at its face, but perhaps you do not know that I patented a lock in 1880 which has no projection at its face, and which will do for either hand of door, and we have been making them all the time.

The action before Mr. Justice Romer was for infringement, but Tucker had patented no projection, while I had patented the automatically wedging of a door, to prevent it rattling, and also to prevent the door handle being in the fast position if the door was open or not wedged fast.

Mr Justice Romer, no doubt, saw clearly that my main bolt, leaving the striking plate last in opening the door, and coming in contact with the striking plate first in closing the door, both increased the lasting qualities and prevented the wedge bolt being shot out and the handle being in the fast position when the door was open.

Yours, &c.,
Joseph Kaye.

Patent Lock Works, South Accommodation Road,
Leeds, 24th April, 1891.

THE ROYAL NAVAL EXHIBITION.

Since we last referred to this Exhibition great progress has been made, and, judging from a recent visit, it is not improbable that it will be quite ready for the opening ceremony, which is fixed to take place to-morrow.

At the time of our visit most of the galleries were practically finished, and some of the exhibits were in position. Water has been let into the new lake, which is a well-constructed cement-lined basin, 250ft. long, 150ft. wide, and 5ft. deep, in which will be shown in action miniature ironclads, complete with guns and machinery, torpedoes, lifeboats, &c. Amongst numerous other things of interest which will be found in the extensive grounds we may mention a North Sea trawler, which has been brought as it stands, and with some difficulty, from Yarmouth, and a full-size model of Nelson's historic ship "Victory." There is also a pavilion, in which models of the magnificent fleet of steamers owned by the P. & O. Company will be exhibited.

Digitized by Google

The model of the Eddystone Lighthouse, which we illustrated in our issue of the 10th ult., is completed as regards the exterior. About a thousand men are at present engaged in the work of putting the Exhibition in readiness for the opening.

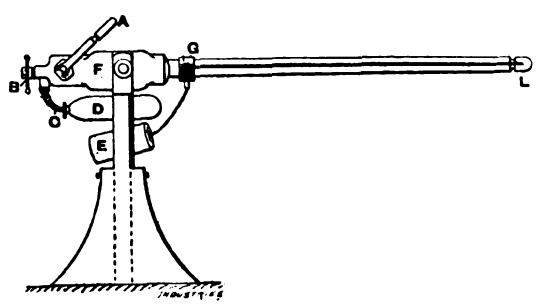
Altogether the authorities are to be congratulated on the progress which has been made in the work of organising what promises to be a most interesting Exhibition. We intend at a later date to refer to some of the principal exhibits in detail.

TRIAL OF H.M.S. "VULCAN."

On Thursday, the 23rd ult. the trial of the above ship took place at Spithead. Perhaps rather unusual interest attaches to this trial as the "Vulcan" occupies a unique position in the Navy, the ship which she is to supersede —viz., the "Hecla"—not having been designed especially for her present service, but being originally a merchant steamer, and adapted to her present use after having been purchased for the Navy.

The official designation of the "Vulcan" is "Torpedo Depôt Ship," but this hardly conveys a full idea of her capabilities, which would be better described by "Torpedo Boat Depôt and Floating Workshop." She is a vessel of 350ft. length by 58ft. beam, displacement 6,620 tons, carrying 6 second-class torpedo boats, 1 vidette boat, and 2 ordinary service steamboats. These boats would in action, be despatched supplied with their torpedoes, which they could replenish when required from the stock carried on board. The workshop is for the purpose of effecting any repairs necessary either in the "Vulcan's" own boats, or in those of the fleet to which she would be attached. The ship herself, although not primarily intended for fighting, has considerable powers of defence and offence, being supplied with eight 4·7in. quick-firing guns and twelve 3in. ditto; in addition she has for the discharge of torpedoes a stern tube and bow tube, and also two submerged tubes in the torpedo room. The fitting of these latter was not provided for in the original design, and has caused some delay in the trials, the ship having been otherwise ready some months ago.

In the "Hecla" the means of hoisting the boats in and out are provided by the masts and derricks, but in the "Vulcan" special arrangements are provided in two cranes, worked by hydraulic gear, by Messrs. Sir W. Armstrong & Co. These cranes are pivoted close to the side of the ship, passing through the decks between rollers, and bearing on a footstep attached to a bearer built into the bottom of the ship. Their height is 63ft., and overhang 38ft., and when not in use they are turned inboard and connected together by a link. It can be imagined that they give a somewhat strange appearance to the ship—so much so, that one might imagine that a piece of the dockyard had got out to sea. The hoisting is effected by two rams, 17½in. diameter and 10ft. stroke, having a lifting power of about 30 tons, the weight of a boat complete being about 17 tons. The cranes will be tested to hold 40 tons. For slueing, rams, 16in. diameter and 6ft. 9in. stroke, are provided. These cranes afford, of course, a much readier method of dealing with the boats than the masts and booms of the "Hecla," but they are looked upon with some distrust by naval men. In one particular there certainly seems reason for this, in that no control is provided for other than that afforded by the rams. These apply their power to the vertical post, and not far from its axis, and it is quite conceivable that in a seaway the rolling of the ship might cause the crane to give trouble. To prevent this it is proposed to fit guys to the ends of the cranes, but as they are at the side of the ship, considerable difficulty will be found in devising any guy which can check an inboard roll. The subject is, however, now under consideration.



The workshop would be sufficient for quite an average size establishment on shore, containing, as it does, five lathes, two shaping and two drilling machines, slotting, shearing, and punching machines, a circular saw and bench, a blacksmith's shop, moulder's shop with hot-air furnace, and about a dozen vices, all of which, judging by the experience of the "Hecla," will be kept well employed. The workshop machinery is driven by its own engine, and it contains, in addition, a dynamo driven by one of Willans' engines. Of these there are three altogether provided, each capable of developing 400 amperes at 80 volts, at 400 revolutions, and self-regulating from 10 to 400 amperes. Messrs. Willans claim that these engines and dynamos develop an electrical horse-power for 29lb. of water per hour, which is a remarkably good result.

The main engines are by Messrs. Humphreys & Tennant, and are of the type of which they have supplied so many good examples to Her Majesty's Navy. They are triple-expansion, with cylinder diameters 40in., 59in., and 88in.; stroke, 4ft. 3in.; and were estimated to develop 12,000 i.h.p.—*i.e.*, 6,000 each set—at 100 revolutions with steam of 150lb. pressure. This result was to be obtained with forced draught of 2in. air pressure, and, with open stokeholds, 7,200 i.h.p. was to be maintained for twelve hours continuously. The manner in which modifications of the original conditions for these and other engines have been made necessary has been well discussed lately, so it will be sufficient to say that the task set in the recent trial was to obtain 8,000 i.h.p. for eight consecutive hours with not more than ½in. air pressure. The boilers are five in number—four main boilers, double-ended, each containing six furnaces, and one auxiliary boiler, single-ended, with three furnaces. The main boilers had each originally one common combustion chamber for the six furnaces, but brick partitions have now been erected, dividing the combustion chamber into six parts. The furnaces have also been shortened by bricking up the ends of the bars, so that the total grate surface of the main boilers has been reduced from 600 square feet to 488 square feet. The reasons for these alterations have been already discussed in our account of H.M.S. "Pallas"—see *Industries* of the 27th February.

The result of the trial on the 23rd ult. must, on the modified conditions, be considered satisfactory, the mean indicated horse-power obtained being 8,166, and the machinery working in a perfectly satisfactory manner. No doubt, so far as the engines are concerned, they could develop the 12,000 h.p. for four consecutive hours, as in the original contract, and for the causes which have necessitated the alteration of the boilers they cannot be held responsible. The speed obtained was 18½ knots, the engines at the time developing 8,300 h.p. A further series of trials at progressive speeds of 10, 12, 14, 16, 18, and 20 knots are taking place at the date of going to press, during the latter of which the use of forced draught will, of course, be necessary. In this case also the whole of the five boilers will be used, giving an extra 55 square feet of grate area, and after this trial the engines will, if found satisfactory on opening up, be accepted.

A PNEUMATIC LINE-THROWING GUN.

Visitors to the forthcoming Naval Exhibition will be able to see an exhibit by Commander John D'Arcy Irvine, R.N., in the Sepping Gallery, who will have on view his pneumatic gun, which is particularly intended for saving life at sea, but which can also be put to various other uses. The accompanying illustration represents a side elevation of this gun, in which A represents the firing lever, B is a screw jamb valve, C and D are a connecting tube and compressed air reservoir, E is a cop for holding the line, F is the air chamber, G is a collar upon the barrel, to which is connected the rope by means of a wire, and L is the projectile. To operate the gun it is first necessary to admit a supply of air under a pressure of 2,400lb. per square inch into the air chamber F by means of the valve B, a process which occupies only a short period of time. The valve B is then closed again, and the lever A pulled towards the operator, thereby admitting the air pressure to the

rear of the projectile, which is carried forward at a great velocity. The rear end of this projectile is tubular and externally threaded to fit a pair of gripping jaws inside the barrel, which hold the projectile against the pressure of the air until the desired moment when the aforesaid movement of the hand lever A releases the grip. The head of the projectile shown is solid, and has a transverse perforation, through which a cord is passed having its ends joined to form a rearwardly extending loop. It is found essential for the successful flight of the projectile that the pull of the line should be exerted at its rear end, and in order to achieve this the loose slide collar G is used, having attached to it the cord above referred to. This in turn is connected to the line proper.

Many opportunities for the successful use of such an apparatus will readily suggest themselves. It might be successfully applied, for instance, in cases of fire on land, for throwing a rope to the rescue of persons in the upper floors of a burning building. The apparatus, we are informed, has been put to various kinds of tests, and has given general satisfaction. The inventor is also bringing out a shoulder gun for similar purposes, but the propelling power of this is to be derived from gunpowder.

SHIPBUILDING NOTES.

On the 20th ult. there was launched from the yard of the Naval Construction and Armaments Company, Limited, Barrow-in-Furness, a dredger, for the European Commission of the Danube. Her dimensions are:—Length, 124ft.; breadth, 28ft.; and depth, 10ft. She was named, after the President of the Commission, the "Sir William Hartley." She is furnished with the latest improvements, and will be fitted with a set of triple-expansion engines.

On the 21st ult. the s.s. "Coringa" (late P. & O. "Bangalore") went down the river for loaded speed trial over the measured mile. The old engines of the "Coringa" have been replaced by a new set supplied by Messrs. Fleming & Ferguson, engineers, Paisley, of their patent improved quadruple-expansion type, having cylinders 22in., 30in., 40in., and 60in., by 36in. stroke. At the trial the vessel carried a deadweight cargo of 3,000 tons, and drew 22ft. mean. The engines indicated 1,500 h.p. on trial, and the speed obtained was 10½ knots over the measured mile at Skelmorlie, a speed considerably in excess of contract.

On the 23rd ult. the s.s. "Pembridge," a steel screw steamer built by Messrs. Sir Raylton Dixon & Co., Middlesbrough, took her trial trip from the Tees. This vessel, which has been built to the order of Messrs. J. Temperley & Co., of London and Newcastle, is built on the web-frame principle. Her leading dimensions are:—Length, over all, 323ft. 6in.; breadth, 41ft.; depth, moulded, 23ft. 1½in., with a deadweight capacity of about 4,300 tons. Her engines have been fitted by Messrs. S. Richardson & Sons, of Hartlepool, on the triple-expansion system, with cylinders 23in., 38in., and 62in., by 42in. stroke.

On the 25th ult. there was launched from the yard of the Tyne Iron Shipbuilding Company, Limited, of Willington Quay-on-Tyne, the steel screw steamer "Cape Corrientes," of the following dimensions:—Length, 300ft.; breadth, 38ft. 8in.; depth, 23ft. 2in. amidships; and to class 100 A1 at Lloyd's. This vessel has water ballast fitted on the cellular system. The engines, which are to be supplied by the North-Eastern Marine Engineering Company, Limited, are of the triple-expansion type, having cylinders 23in., 38in., and 63in., by 42in. stroke, and working at a pressure of 150lb.

On the 25th ult. Messrs. Richardson, Duck, & Co. launched from their building yard, South Stockton-on-Tees, the steel screw steamer "Nutfield," of the following dimensions:—Length, over all, 307ft. 3in.; breadth, extreme, 40ft.; depth, moulded, 21ft. 8½in.; tonnage, gross, about 2,550 tons. This vessel, which has been built to the order of Messrs. Tyler, Bright, & Woods, Leadenhall Street, London, is classed 100 A1 at Lloyd's, and has been built under special survey. The vessel is fitted with water ballast on the cellular principle. The engines are by Messrs. Thos. Richardson & Son, of about 200 n.h.p.

On the 25th ult. Messrs. Ropner & Son launched the steel screw steamer "Phyllis," of the following dimensions, viz.:—Length, over all, 301ft.; breadth, 39ft.; depth, moulded, 21ft. 10in. The vessel has a cellular bottom for water ballast, is built on the web-frame principle, classed 100 A1 at Lloyd's, and will carry 3,600 tons. Her engines are triple-expansion, by Messrs. T. Richardson & Sons, Hartlepool, having cylinders 22in., 36in., and 59in., by 39in. stroke, with two large steel boilers working at 160lb. The steamer has been built to the order of Messrs. J. S. Allison & Co., West Hartlepool.

Reviews.

Handbook for Mechanical Engineers. By Henry Adams. Second Edition. London: E. & F. N. Spon.

In the preface to the first edition of this work, which was issued seven years ago, it was described as an effort to write out a part of the student's notes for him, in the hope that he might thereby be enabled to give more undivided attention to the illustrations and descriptions of mechanical details and operations put before him in the lectures, and was not intended in any way to supersede the ordinary text-books, but simply to supplement them. The favourable reception which was given to the work has induced the author, or, more correctly, the editor, to re-cast the whole under a new title, and to include additional matter, with the object of rendering the work still more acceptable to engineers in practice. He points out that busy men must have facts and opinions put before them briefly, and he has endeavoured to convey his information in as condensed a form as is compatible with accuracy. The work is, of course, largely a compilation, but the names of the sources from which it is extracted are always given, and these seem to have been selected with great care. All the ordinary branches of mechanical engineering are

THE ELECTRIC LIGHTING PLANT OF THE METROPOLITAN POLICE OFFICES.

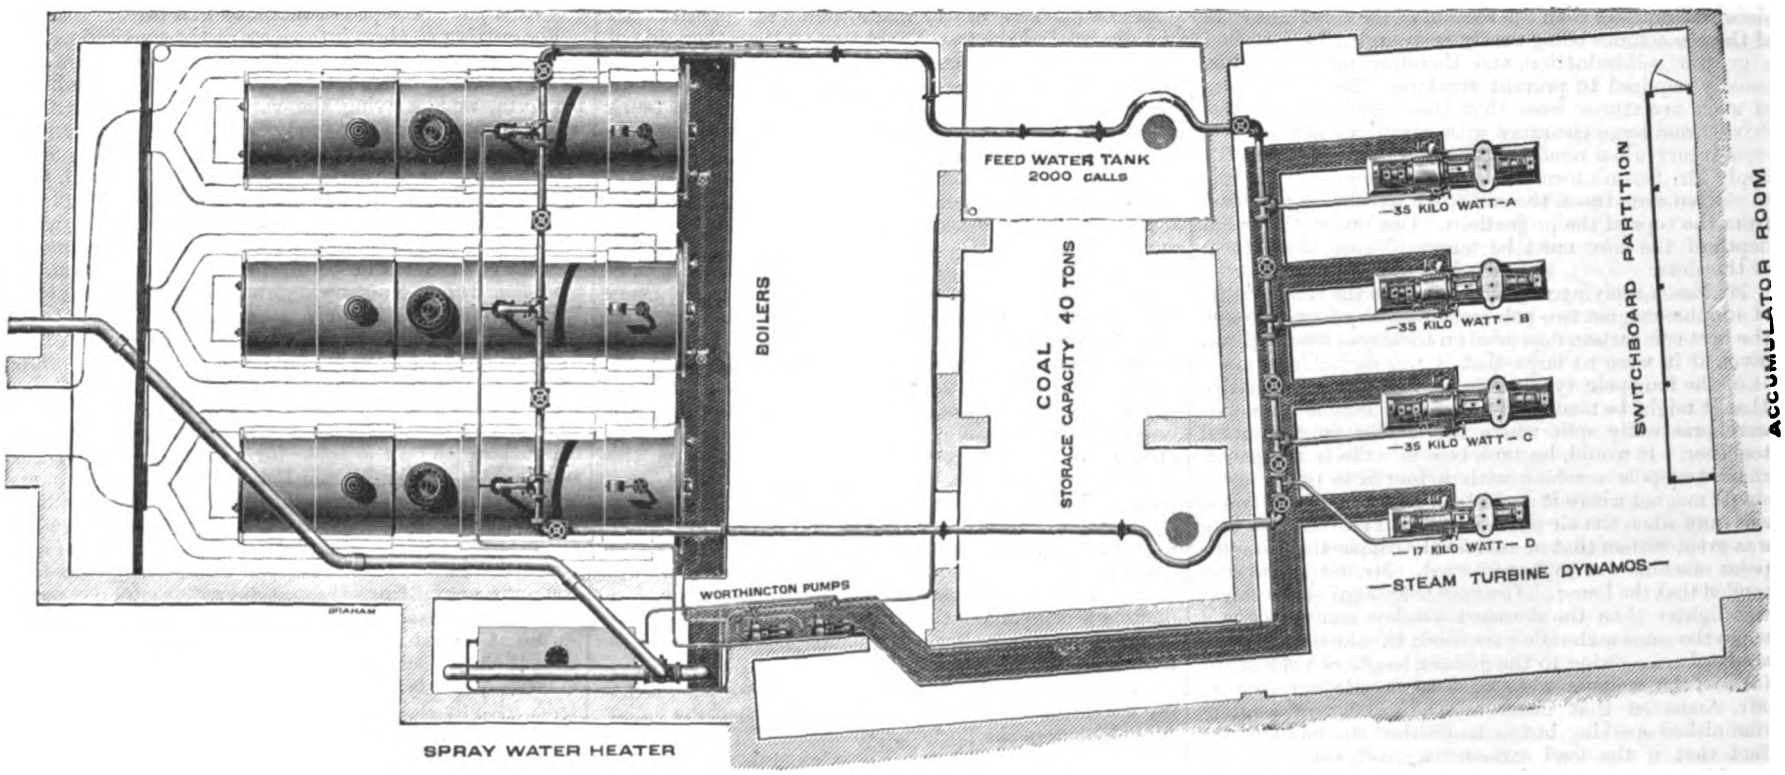

FIG. 1.—PLAN OF ENGINE ROOM.

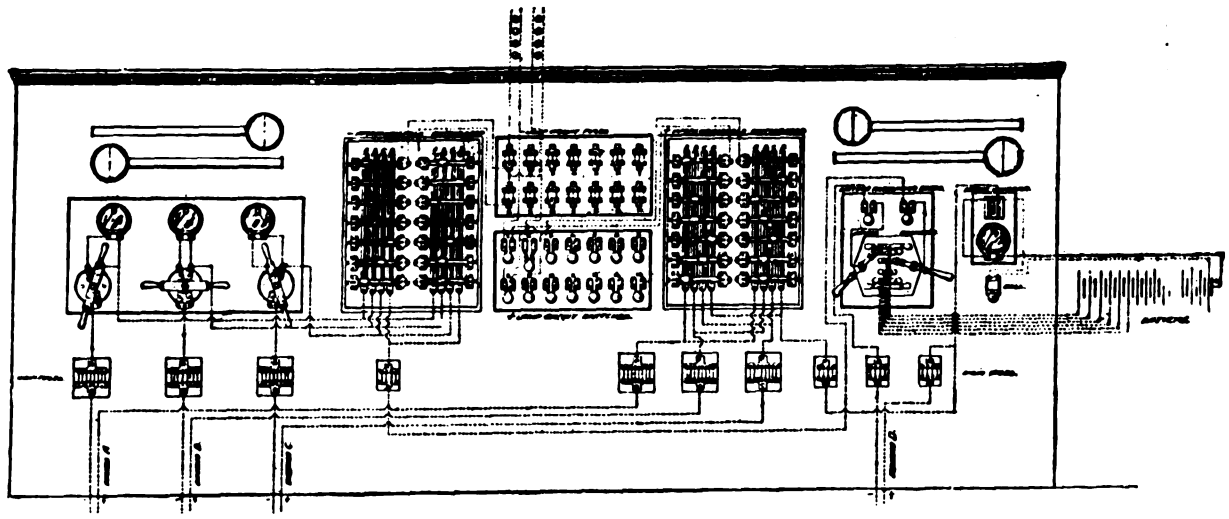

FIG. 2.—DIAGRAM OF THE SWITCH BOARD.

The engine-house has been excavated in the yard, between the main building and Whitehall, and the whole of the generating plant has been placed well away from the offices. The steam plant consists of three Lancashire boilers by Messrs. Davey, Paxman, & Co. The feed-water heater is of a special type, consisting of a tank into which the feed-water is admitted by a ball valve, the water being blown into a spray by the exhaust steam from the engines, which enters immediately under the ball valve. Worthington steam pumps are so arranged as to draw water from the feed-water heater or direct from the main feed-water tanks.

The electrical power is obtained from four of the latest radial type of Parsons steam turbines and dynamos, three of these being capable of giving an output of 35,000 watts each, and a smaller generator, giving an output of 120 amperes by 130 volts, for the charging of accumulators. The accumulators consist of 106 cells, capable of discharging at a rate of 120 amperes for nine hours for the supply of 200 lamps of 16 c.p. each. The ordinary lighting for the building is supplied direct from the steam turbine dynamos. The battery for supplying lamps at night is charged from the smaller generator during the day, and excepting cases of emergency. Every alternate lamp throughout the building is supplied from a different circuit, so that, in event of a breakdown, only half the lights would be extinguished. The generating plant also provides electrical power to the printing office, where the police reports and notices are now all printed by a machine worked by an electro-motor.

New Scotland Yard is, it is believed, the first Government office lighted entirely and exclusively with the electric light. The whole installation is now practically complete, and the new illuminant is giving general satisfaction to the occupants. The whole of the work has been carried out in the most complete way by Messrs. Drake & Gorham, under the supervision of Mr. A. Campbell-Swinton as consulting engineer.

We give above, in Figs. 1 and 2, a plan of the engine-room and a diagram of the switch board, which explain themselves.

fairly well covered, and a copious index of subjects makes the contents easily available for reference. We have much pleasure in commending it.

MANUAL TRAINING IN EDUCATION. By Professor C. M. Woodward. London: WALTER SCOTT.

This book forms one of the convenient and interesting series published by Mr. Walter Scott in the "Contemporary Science Series," and at the present time, when the subject of technical and manual instruction is being so much discussed, will be found valuable in many respects. Notwithstanding all that has been said and written on the subject of technical education, the majority of people have still a very hazy idea of either its meaning or scope. Mr. Woodward's book will be most useful in showing how a system of manual training is to be carried out, especially in those departments which will be of most use to young engineers, such as turning, carpentry, and smithing. We must confess, however, that the title of the book is rather misleading, as there are many other exercises in manual training which would be of great use to scholars of both sexes, beginning with those which are usually given in a Kindergarten school. So far, however, as he goes, Professor Woodward gives many useful hints about drawing and its relations to woodwork, and examples of the work which may be done in joinery, wood turning, pattern making, moulding, and smith work. The book, however, is not a complete text-book on these subjects, but a great part of it is taken up with discussions on the educational aspects of the question, the defective nature of the traditional curriculum, the remedies proposed, the scope of manual training and its results. The author is somewhat combative, and states what he considers the fallacies connected with manual training, and replies with vigour to criticisms which have been made on his proposals. On one point we are glad to see he is quite clear. He comes to the conclusion "that the more a shop becomes a factory the less it is a school. Instead of planning the shop to turn out merchandise, it should be planned to turn out well-trained boys. Clear-headed, intelligent boys should be the only article put upon the market."

THE ELECTRIC LIGHTING PLANT OF THE METROPOLITAN POLICE OFFICES.

THE whole of the new Metropolitan Police Offices at New Scotland Yard have been fitted with the electric light. There are about 1,100 lamps at present fixed, and the total number will eventually be about 1,250.

INSTITUTION OF ELECTRICAL ENGINEERS.

AT a meeting of this Institution on the 23rd ult. the discussion on the paper entitled "The Design of Multipolar Dynamos," by Mr. W. B. Esson, was continued.

Mr. Mordey read a communication from Mr. W. B. Sayers, in which it was pointed out that Mr. Esson had

Digitized by Google

made no mention of slotted armatures in his paper, although many of the results contained in it could, by suitable modification, be applied to them. A mistake made by nearly all designers in considering this kind of machine was to assume that they required much less magnetising power than ordinary smooth core machines. The *sine quâ non* of a good slotted armature machine was that the sum of the areas of the teeth under a pole piece was not less than the section of the core. The coils of these machines being nearly surrounded by iron had a greater self-induction, and therefore more lead was usually required to prevent sparking. The advantages of such armatures were that they combined positive driving and large clearance with considerable immunity from injury when removed for inspection or repair. To apply Mr. Esson's formulæ for the "volume of current" to slotted armatures, the air space should be reckoned from the tops of the projections. Obviously, the radial depth of the core must be measured from the bottom of the slots.

Mr. Esson, replying, said with regard to the comparisons of a double-magnet two-pole machine with a four-pole one, the best comparison depended on the size of the machine. Even if it were so large that it was desirable to make it of the four-pole type, there was still the alternative that it might be made two-pole if the double horseshoe were practically split where the similar poles abutted together. It would, he said, be a mistake to compare a small two-pole machine with a four-pole one, since a single magnet where it could be used was better; and it was only when the air gap necessary to prevent sparking was greater than that needed for the copper that a multipolar machine was to be preferred. Mr. Kapp had contended that the four-pole Gramme field (Fig. 7 of the paper) was lighter than the double horseshoe shown in Fig. 4 when the same materials were used; this, he thought, was a mistake, for owing to the greater length of yoke in the former, the weights were as 4 to 3. He agreed with Mr. Andersen that increasing the number of sections diminished sparking, but he had wished to emphasise the fact that if the load exceeded a given value, no non-sparking position could be found for the brushes whatever the number of sections might be. He had then pointed out that in no actual machine did the load exceed half the limiting value. He entirely agreed with Mr. Crompton about the economy of material effected by making multipolar machines, for his own experience showed the saving to approach very closely the 40 per cent. mentioned by Mr. Crompton.

THE PHYSICAL SOCIETY.

At a meeting of this Society on the 17th ult., Professor W. E. Ayrton, F.R.S., President, being in the chair, a paper was read "On a Property of Magnetic Shunts," by Professor S. P. Thompson. After referring to a few instances in which magnetic shunts are employed—as, for example, the ordinary magnetic medical coil, and Trotter's constant-current dynamo—the author said that the particular property he wished to speak of was the time taken for such a shunt to lose its magnetism as compared with the other branch of the magnetic circuit. If these times were very different, unexpected results might be produced, and these might be regarded as being due to a kind of magnetic time-constants. Short pieces, as was well known, demagnetise much more rapidly than long ones, particularly if the latter form, or be part of, a closed magnetic circuit. Hence, in alternators such as Kingdon's keeper dynamo, in which both magnets and armature are stationary it was important that the revolving keepers should be short. The most important application of a magnetic shunt occurred, he said, in d'Arlincourt's relay.

Professor Perry asked if any experiments had been made to test whether throwing back actually occurred. He also inquired whether such action would be augmented or otherwise by having a thick copper tube round the yoke, or by laminating the iron.

Mr. Blakesley asked if placing a yoke across A B in the diagram shown would not improve the action.

The President said he would be glad to know whether the relay was any more sensitive than an ordinary one as regards the ampere-turns or the watts required to actuate the instrument. In India he remembered that they used inductive coils shunting the ordinary relays, in order to expedite the action and to avoid confused signals arising from the electrostatic capacity of long lines.

In reply, Professor Thompson said he had tried an experiment on a horse-shoe electromagnet, and found evidence of throwing back when working near the bend or yoke. Putting a yoke across A B would, he thought, tend to neutralise the effect desired.

Afterwards a paper on "An Alternating Current Influence Machine" was read by Mr. James Wimshurst. This machine consists of a varnished glass disc, with or without metallic sectors, mounted on an axis and rotating within a square wooden frame fixed in the plane of the disc. The frame carries four square glass plates, each of which has one corner cut away so as to clear the boss of the disc. These plates are placed one at each corner of the frame, alternately on the two sides, and the disc revolves between them. There are thus two plates on one side of the disc situated at opposite ends of a diagonal of the frame, and two on the other side of the disc at opposite ends of the other diagonal. Tinfoil sectors fixed to the outer sides of the plates act as inductors, and wire brushes connected with them touch the disc about 90 degrees behind the centre of the inductors. The peculiarity of the machine is that, although sparks can be readily obtained from it, a Leyden jar cannot be charged by bringing it to one of the terminals. From this the author concluded that the electricity produced was alternately of positive and negative sign, and this he showed to be the case by means of an electroscope. The alternations, he said, occurred about every three-fourths of a revolution, the suspended paper discs which he used as an electroscope remaining apart for that period and collapsing during the next quarter of a turn. Using discs with various numbers and sizes of sectors the author finds that the smaller the sector and the fewer the number the greater the quantity of electricity produced. Plain varnished glass is the best in this respect. Such a disc, however, does not excite itself quite so freely as one having numerous metallic sectors. By removing two of the inductors, and placing an insulating rod carrying collecting brushes at its ends across a diameter of the disc, the machine was used to produce direct currents. Numerous discs and various shaped inductors accompanied the machine, by means of which a Holtz, Voss, or ordinary influence machine could be imitated.

Professor S. P. Thompson congratulated the author on the most interesting and puzzling machine he had brought before the Society. He inquired if the machine would work if the direction of rotation was reversed or if two of the inductors were removed, and also whether all the four inductors are electrically of the same sign at the same instant.

In reply, Mr. Wimshurst said the machine would not excite if the direction of rotation be changed without also changing the direction of the brush arm, but it would work as a direct-current machine when two inductors were removed.

The next paper was "On Erecting Prisms for the Optical Lantern, and on a New Form of Erecting Prism made by Mr. Ahrens," by Professor S. P. Thompson. The ordinary form of erecting prism—viz., a right-angled isosceles one—was, the author pointed out, open to the objection that the top halves of the faces enclosing the right angle were nearly useless, for only the light which, after the first refraction, is totally reflected by the hypothenuse face, can be utilised. The fraction of the side which is useful varies with the refractive index, being ·46 when $\mu = 1{\cdot}5$, and ·525 when $\mu = 1{\cdot}65$. To increase these proportions, prisms with angles of 105 degrees and 126 degrees have been used by Wright and others, and in some cases the prisms have been truncated. With such large angles much light is lost by reflection. Bertin employed two truncated right-angled prisms placed base to base, with an air film between them. Nachet has also made erecting prisms for microscopes, in which internal reflections occur from faces inclined at an angle of 81 degrees to each other. This form of prism suggested to Mr. Ahrens the new form now shown, and which may be described as a long right-angled prism whose ends are cut off so as to be parallel to each other and inclined at 45 degrees to the hypothenuse face. The longitudinal acute angles, not being required, are truncated. Light falling parallel to the axis on one end of the prism is refracted, and after internal reflections emerges parallel, but perverted. It is claimed that this form of prism gives, weight for weight, a larger angular field than any previously made. The performance of the new form of prism, and also of the ordinary forms, was tested before the Society.

At the close of the meeting it was announced that the next meeting would be held at Cambridge on May 9th, instead of May 8th, as previously intended.

THE MANUFACTURE OF SOAP.

By W. Lawrence Gadd, F.I.C., F.C.S.

VI.

(*Continued from page* 403.)

Stamping and Packing.—The soap bars, after standing in open pile for a day, are either packed at once in boxes, or, if not required immediately for packing, are "close piled" or packed together in solid blocks. Before placing in the boxes, the bars are usually stamped in the centre and at both ends of one face, corresponding to the three separate pounds into which the bar may be divided by the retailer, with an impression of the name of the soap and of the maker. This is done either by a small hand stamp, with which the bar is struck, or by a lever press giving the three impressions at one stroke. Many kinds of household soaps are, however, sent out in the form of moulded tablets, the bars being divided into 1lb. pieces, and each piece stamped or moulded in a press.

For cutting the bars into pieces of the required weight or size, various machines are used, the most common consisting of an upright frame placed in front of a table or platform, and carrying the vertical, stretched cutting wires, against which the bars of soap are pressed, and so divided. A number of bars are laid side by side on the platform, and the rearmost one is pushed forward, thus forcing the remainder, one after the other, through the wires. Another machine, on a similar principle, has a moveable wooden back-piece, which is worked forward by means of chain or toothed wheel gearing, and, the back-board and wire-carrying frame both being tall, there is the advantage, with this machine, of being able to cut three or four layers of bars at once. In this way, from forty to sixty bars can be cut each time the travelling back-piece is wound forward. Some time is, however, lost while drawing back the pushing board to its original position, which has to be done before a fresh supply of soap bars can be stacked on the table for cutting; but a machine supplied by Messrs. Martin Perls & Co., of London, and shown in Fig. 9, overcomes this difficulty to some extent, by the frame or gauge carrying the wires travelling backwards and forwards along the table, a row of soap bars being laid at one end of the table during the time the wires are cutting others at the other end.

One of the best machines I have seen is perhaps that in use at the Sunlight Works of Messrs. Lever Brothers, as it is simple, automatic, and capable of rapidly cutting a large quantity of soap. It consists of the ordinary table with fixed wires for cutting one layer of bars, which are pushed forward by an iron bar attached at each end to an endless chain running on rollers at each side of the table. The rollers, geared to the power shaft, are constantly kept steadily running, and the endless chain moves the pushing bar forward along the table until near the fixed cutting wires, where it falls through a slot and returns under the platform to the far end, to be again carried forward. There are two of these bars, the second appearing at the one end of the table as the first disappears through the slot at the other end, and one of these machines, working continuously in this way, will cut a large quantity of soap, the attendant merely placing the bars side by side on the table, to be pushed forward and pressed through the cutting wires by the travellers. The end of the table, where the fixed wires are placed, is

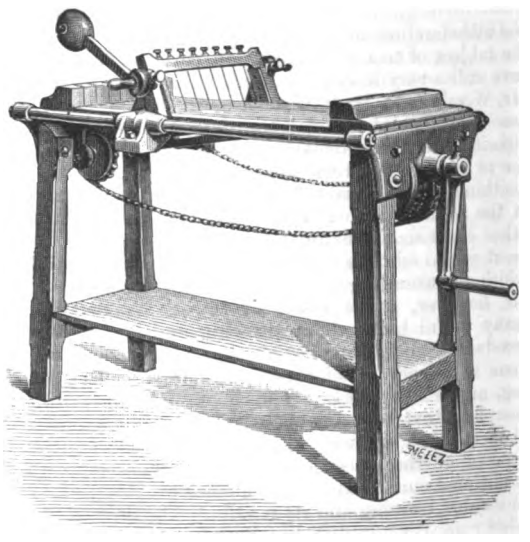

Fig. 9.

in contact with a conveyor, consisting of a pair of endless bands running on rollers and connected together by a number of flat pieces of wood about 2in. wide. The pieces of soap as they are cut are pushed on to this conveyor, and are carried by it into another room to the stamps, for compression into the required shape of tablet. These extremely useful labour-saving conveyors are largely used throughout the extensive and modern works at Port Sunlight, similar but more substantial ones, running on metal wheels, carrying the wooden boxes from the box-making machines to the packing room, and, when packed, from thence to the warehouse and to the sidings and wharfs for shipment

The stamps most commonly in use are worked by hand power, and are of various designs, the variation being generally in the method of applying the pressure. They consist essentially of two brass plates or dies, bearing in

Digitized by Google

relief or sunk characters the impression intended to be given to the top and bottom faces of the tablet, combined with a brass ring which surrounds the soap and forms the mould in which it is compressed by the force of the blow into the desired shape. The pressure is applied generally by forcing down a lever attached to a counterbalanced wheel, the rebound of which raises the top die and ring after the stroke, and so leaves the compressed tablet free to be removed and packed. To prevent the soap from sticking to the mould and dies, they are occasionally sponged with a solution of salt. Fig. 10 is an illustration of a hand stamp made by

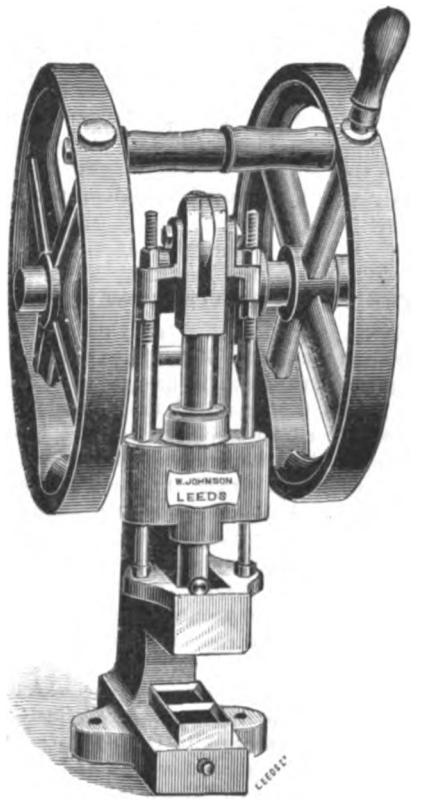

Fig. 10.

Mr. W. Johnson, of Leeds. The same maker manufactures a stamping machine to be worked by power, which is quicker than the hand machine, stamping, as it does, as many as forty tablets per minute. This is shown in Fig. 11. The cut piece of soap is placed on the table in front of the feeding arm, on the left of the illustration, which moves forward and pushes the same under the pressing head carrying the top die. The soap is then allowed to drop into the mould, which is let into the table; the press head descends with the necessary force to give the impression of the dies and mould the soap into shape, and the finished tablet is then raised to the level of the table, the act of feeding the next piece delivering it on the right of the machine, ready to be packed. In England the tablets are usually only stamped on the top and bottom faces, but in some parts of the Continent there is a demand for tablets stamped on all the six faces, and this is achieved by a special stamp, in which the dies for impressing the side and end faces of the tablet are hinged, as shown in Fig. 12, and fall back to allow the soap to be inserted or removed, but automatically close on the tablet when the down stroke is given, the ring of the mould coming down and encircling them with sufficient force to give the impressions.

The foregoing describes the general process for the manufacture of ordinary household soaps, such as "pale" or "primrose," mainly from tallow or similar fat and rosin; also brown soaps of various kinds, made from "nigre," brown tallow, palm oil, rosin, &c.; and other varieties of soap. Some of these, especially when run heavily with silicate of soda or other adulterants, are coloured slightly by the addition of aniline and other colours, to give a richer or better appearance, and several of the colours so used are objectionable on account of requiring to be dissolved in caustic soda solution before being added to the soap. A number of the better class soaps are, however, slightly tinted with perfectly harmless colours, amongst which may be mentioned chlorophyll, the green colouring matter of plants. This substance is obtained in the form of a green paste, consisting of chlorophyll ground in oil, and a weighed quantity is rubbed in a mortar with a comparatively large volume of hot cottonseed or cocoanut oil, and the whole added to the soap in the crutching machine. The amount of chlorophyll paste used, varies from $\frac{1}{8}$oz. or more down to $\frac{1}{20}$oz. per cwt. of soap, and should be added soon after the crutching pan commences to fill,

THE MANUFACTURE OF SOAP.

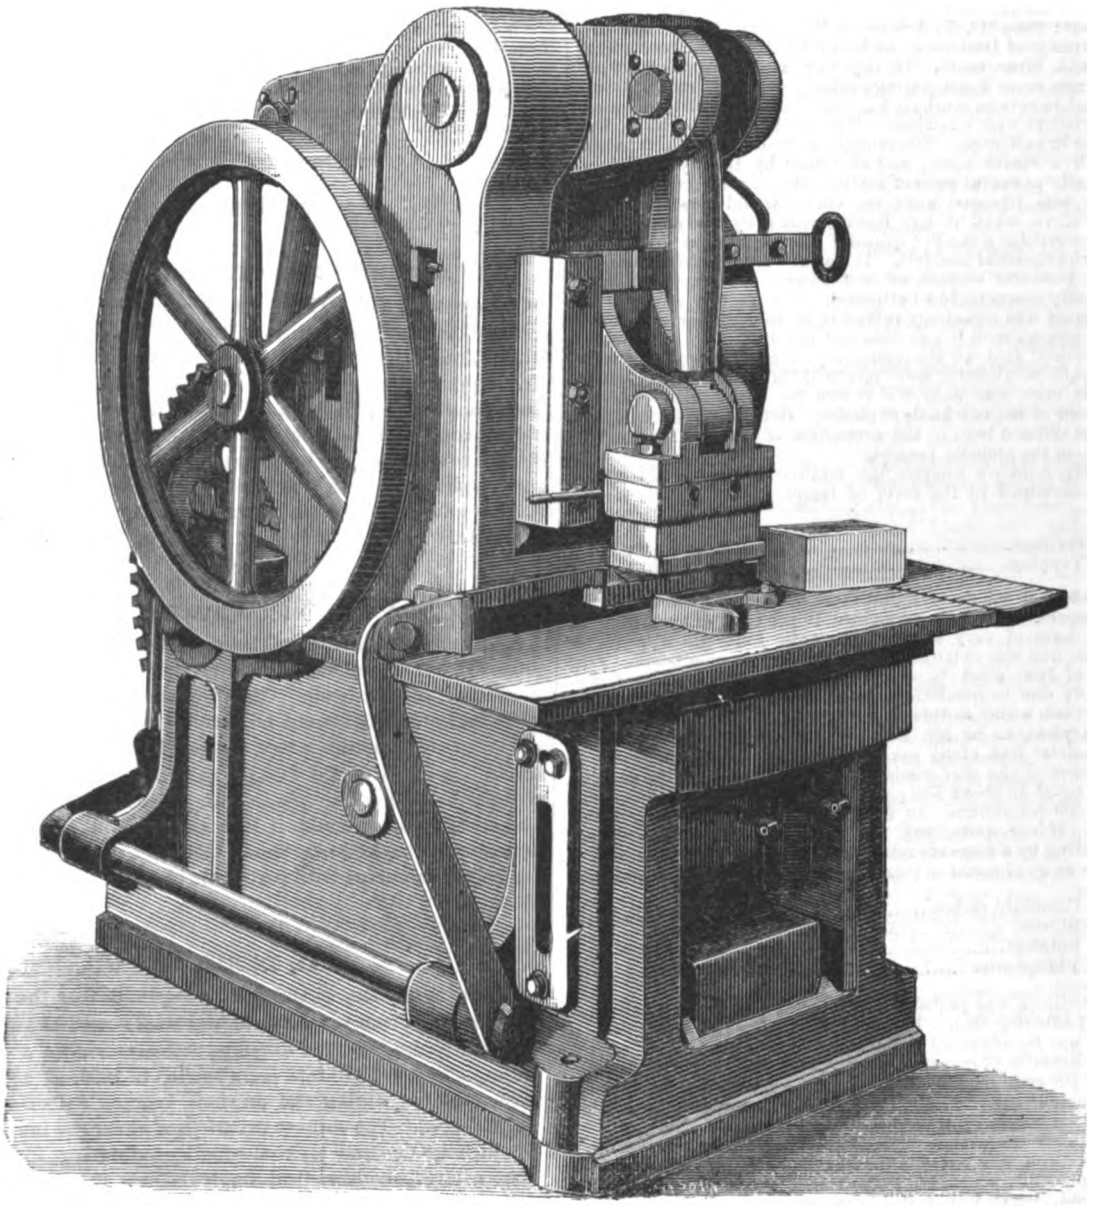

Fig. 11.—General View of Power Stamping Machine.

the mixture of chlorophyll and oil being poured, in a moderately thin stream, into the flowing soap at the orifice of the shoot, which ensures its more thorough mixing than if thrown into the crutcher in one or more separate portions. It is claimed that the addition of the small quantity of chlorophyll given above not only improves the colour of the soap, by neutralising any brownish or reddish tints, but also prevents oxidation and consequent discolouration afterwards.

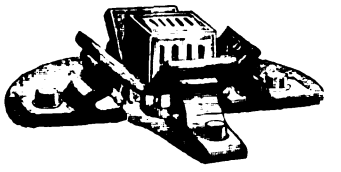

Fig. 12.

A large quantity of household and laundry soap is now made from oil, or oil mixed with a proportion of tallow and rosin, enormous quantities of cocoanut, palmnut, cottonseed, and bleached palm oil being used. The oil soaps have usually a darker, browner, and more transparent appearance than those made from tallow alone, and are apt to become darker and more discoloured by oxidation, on exposure to air; but, at the same time, they have several important advantages. They lather with facility, and the bars do not "dry in" or shrink, and consequently lose their shapes, to anything like the same extent as tallow soaps. The amount of water of constitution is, in oil soaps, greater than in tallow soaps, and, probably on this account, fitted soaps of the former class cannot be run, to any great extent, with silicate or other solution.

(To be continued.)

VARIETIES OF TAP CINDER.*

In the discussion which followed the reading of Mr. Holgate's paper before this Institute, more than a year ago, reference was made to the fact that tap cinder which boils out of the puddling furnace during the working of the charge is much more lively in the tapping waggon than the cinder which is tapped out at the end of the process, and while the latter evolves little or no gas, the former gives off considerable quantities of a combustible gas which burns in jets at the surface of the molten cinder. As some doubt was expressed as to the causes of this difference in behaviour, I asked some of my friends who are connected with the local iron trade to supply me with samples for examination, and venture to-night to bring before you some of the results of the inquiry. I am sorry that circumstances should have prevented my dealing with the matter before.

The physical properties of tap cinder vary considerably with the quality of iron used, the fettling employed, the temperature and rate of cooling, and other circumstances; but in spite of these variations it will be noticed that the two kinds of cinder, namely, "boilings" and "tappings," each possess characteristic appearances which render them easily distinguishable. Thus, while the boilings are usually more or less hollow, possessing a honeycombed or vesicular structure, frequently showing bright crystalline faces, and being more readily fractured by a blow, the tappings, on the other hand, are usually compact, heavy, and strong, requiring more force to cause fracture, and showing much less porosity than is seen in the boilings. Both the total and the relative weight of the two kinds of cinder vary considerably according to circumstances. Mr. A. E. Barrows, of Bloomfield, has been good enough to take the weights of iron used and of cinder obtained in producing best iron, and his results are as follow:—

Weight Charges.			Boilings.			Tappings.			Yield.		
Cwt.	Qs.	Lbs.	Cwt.	Qs.	Lbs.	Cwt.	Qs.	Lbs.	Cwt.	Qs.	Lbs.

4	1	18	1	0	0	1	1	12	4	2	14
4	1	18	1	0	20	1	2	0	4	2	7

These figures show that the boilings and tappings produced were of nearly equal weight, and each was in round numbers one-fourth of the yield.

* Paper read by Mr. Thomas Turner before the South Staffordshire Institute of Iron and Steel Works' Managers on the 11th ult.

Digitized by Google

In working common iron for sheets the weight of boilings and tappings was also about equal. On the other hand, Mr. Yeomans informs me that at Old Hill he frequently boils out nearly the whole of his cinder, leaving no more in the furnace than can with advantage be used in the subsequent heat. For my experiments I obtained samples of boilings and tappings, both taken from the same heat: from Mr. T. Ashton, of Netherton, three heats; Mr. R. M. Tolley, of Darlaston, one heat; and Mr. A. E. Barrows, of Bloomfield, three heats. In this way, as the samples were obtained from seven heats, during ordinary working, with different irons and in several works it was considered that fairly representative cinders were examined. The method of procedure was the same in each case. The samples were broken up and passed through a coarse sieve, and examined by the eye and by a moderately powerful magnet for globules of iron; crushing and sieving was repeated until the cinder would pass through a No. 40 sieve, when it was finally treated by the magnet, and from the residue a smaller quantity was very finely ground for use in the chemical analysis. It was not found advisable to use a very powerful magnet, as in that case the slag was itself sufficiently magnetic to be attracted. The portion attracted by the magnet was repeatedly rubbed in an iron mortar and sorted with a magnet until it was obtained free from slag. It was at once noticed that all the boilings yielded globules of metallic iron, while no globules were met with in any of the tappings. Here at once was seen the reason for the difference in the behaviour of the two kinds of cinder. But the three samples of boilings differed both in the proportion of metallic iron and in the size of the globules present.

In Mr. Ashton's samples the relative density of the cinder was determined in the form of lumps at 17° C., the results being—

Boilings	3·71
Tappings	3·75

from which it will be seen that there was no great difference in this respect. The boilings yielded 16 per cent. of metallic iron, in the form of very small shots, while from the tappings no metallic iron was obtained, as I have before mentioned. This yield of iron must be considered abnormally high, and was probably due to insufficient heat during the beginning of the boil. Such a slag as this, if we assume it to weigh one-fourth of the yield, as in Mr. Barrows' experiments, would mean a preventible loss of 3½ per cent. of puddled bar, and this in the course of the year would entail a very considerable amount, being equal to about £50 per week on 300 tons of puddled bar, or £2,500 per annum. In fact, I believe that this slag would nearly, if not quite, pay for the expense of crushing and separating by a magneto machine to recover the metallic iron.

The shots of metal in this case were analysed and contained—

Combined carbon	·88	per cent.
Silicon	·57	,,
Sulphur	·05	,,
Phosphorus	·55	,,

The silicon was probably due in great part to the small quantity of adhering slag. The rest of the analysis shows that the metal was far advanced in the series of changes which occur in the conversion of cast iron into wrought iron, and the presence of ·88 per cent. of carbon sufficiently explains the formation of combustible gas (carbonic oxide) in the tapping waggon, where the metal was in contact with a molten oxidising slag.

Mr. Barrows' sample of boilings yielded only 3 per cent. of metallic iron, which was in the form of larger globules than in the previous case, while Mr. Tolley's boilings only contained 2 per per cent., which was in still larger shots. It appears, therefore, that the greatest loss is noticed when the iron boils over in the slag in the state of comparatively fine division, in which form also it is probably less likely to attract attention. I question whether this loss can be much reduced by the use of the tapping bar as a skimmer during the boiling over, and other similar means; but I am inclined to think that the presence of a perfectly fluid cinder assists the iron to subside more readily, and thus tends to prevent loss.

The various samples of cinder have been analysed, and I hope shortly to have an opportunity of discussing the relative economy of these slags, but it will be sufficient now to say that in my opinion Mr. Ashton's cinder was (apart from the loss of iron above mentioned, and which is unnecessary) considerably more economical than either of the others, while Mr. Barrows' was the purest and most extravagant of the three examined.

In connection with such observations it must, of course, be remembered that in some cases it may be necessary to waste fettling in order to obtain a special quality of iron. The composition of the two kinds of cinder when freed from shots of metal shown by the mean obtained from the seven heats was as follows:—

	Boilings.	Tappings.
Ferric oxide (Fe_2O_3)	6·94	12·90
Ferrous oxide (FeO)	62·61	64·62
Silica (SiO_2)	19·45	15·47
Phosphoric anhydride (P_2O_5)	6·32	3·91
Not estimated (Al_2O_3,MnO,S,&c.)	4·68	3·10
	100·00	100·00

These figures show that the boilings are distinctly more impure than the tappings. The quantity of ferric oxide, which is the most active oxidising agent, is lower in the boilings, and this points to considerable chemical action during the early part of the process. The amount of silica is higher in the boilings, and this is due to the well-known fact that silicon is eliminated very early in puddling. The proportion of phosphorus is also greater in the boilings, and this points to a fact that is, I think, not sufficiently appreciated—namely, that the greater part of the phosphorus is oxidised before the boil commences. These analyses, I think, further show that (since it is necessary to have a certain quantity of slag in order to remove the impurities present, and since, in order to produce a good iron, it is necessary to have a fairly pure tapping cinder) for economical puddling it is necessary to boil away a considerable quantity of the first impure cinder so as to be able to obtain a pure tapping cinder with the use of the smallest possible quantity of fettling. The importance of a high temperature is well known to skilful puddlers, and has been illustrated in these experiments.

I have on previous occasions expressed the opinion that the chemical composition and fluidity of the cinder is of the greatest practical importance in puddling, and at present I believe that one of the readiest and most practicable methods of judging of the economical working of the puddling furnace is to be found by paying attention to the weights and composition of the tappings and boilings. Tap cinder is the puddlers' waste product, and in these days, when waste products are being utilised in all directions, it is certainly of the greatest moment to the ironmaster that his tap cinder should be as small in quantity, and as highly charged with impurities, as is consistent with excellence of manufacture.

Notes.

COMPOUND LOCOMOTIVES IN RUSSIA.

In *Industries*, Vol. VIII., page 169, we published a paper read before the Institution of Mechanical Engineers by Mr. T. Urquhart on the above subject. We now learn from Mr. Urquhart that, out of 143 locomotives on the Grazi and Tsaritsin Railway, South-East Russia, 32 have now been compounded. These compound locomotives, which consist of three classes, all burning petroleum fuel, have made a total mileage of over one million miles since their conversion, and show a mean economy of liquid fuel of 18½ per cent.

A NEW DISINCRUSTANT.

A novelty in the ranks of boiler disincrustants has been proposed, which, unlike many of the nostrums of the kind, is at least fairly rational. The suggestion is made that a bottle of liquid CO_2 should be coupled to the boiler while the latter still contains water, the idea being that the water would become saturated with the gas and dissolve the scale without attacking the plates. Ingenious as the notion undoubtedly is, we doubt if it would work, as the solvent action would be decidedly slow. Moreover, it would only do for boilers incrusted with carbonate of lime or magnesia.

COAL IN RUSSIA.

The coal industry in the Donetz Basin during the past year has not given very satisfactory results, and the quantity transported by the different railways shows a great falling off; 1,863,170 tons were carried in 1890, as against 2,000,705 tons during the previous year, or a decrease of 137,535 tons. The colliery proprietors, under the influence of the large demand for coal experienced during 1888 and part of 1889, made radical improvements in their mines, greatly enlarging the same, and increasing their productive capabilities; but during the past year they have had to gradually retrench, and this year the output will most probably reach its normal figure. The heavy duty on foreign coal and the opening of the port at Marinpol have greatly assisted in developing the export of Donetz coal to the Black Sea ports, at which, during the past year, there is a falling off of nearly 100,000 tons in the quantity of English coal imported.

SLIDE RULE FOR ELECTRIC "WIRING" PURPOSES.

Messrs. Crompton & Co. have sent us an extremely neat slide rule for calculating out everything that has to be known in "wiring." It is the invention of Mr. A. P. Trotter, and is an ingenious combination of three logarithmic or slide-rule scales so arranged that, given, for instance, the number of lamps, say 47, of, say 67 watts each, and the pressure, say 93 volts, and the drop, say 1·5 volts, the mains being, for example, 90 yards long, one can find at once that 7/12 or 19/17 cable should be used. This calculation may be done without the observer having to study simple arithmetic. The little rule also calculates curr ent densities, resistances, maximum current densities, sectional areas, &c., with equal promptitude and accuracy. We hope Mr. Trotter will now turn his attention to a waistcoat-pocket rule for reading directly the most economical mains for a municipal network, the windings of dynamos and transformers, speed of cabling, &c.

NOVEL WEIGHING MACHINE.

Mr. Joce Soler, of Barcelona, has lately invented a novel form of weighing machine, which we recently inspected at the British Travels Agency Company's office, 13, Victoria Street, London, S.W. The machine is designed to weigh either large or small articles, two scale pans, one large and the other small, being provided, the small one weighing one-thousandth part of the other. If a light article is to be weighed, it is placed in the small scale pan and counterpoised by large weights in the large scale pan. If the weight of a heavy article is required, it is placed in the large scale pan and equipoised by a sliding weight on a compound steel-yard. In addition, the weighing machine is provided with a third scale pan, to give or check the price of the article being weighed. The upper edge of the steel-yard is engraved to show various weights, and the lower edge is graduated for money. The rate per kilogramme being known, the money scale pan is moved along the steel-yard to the proper division for the given rate; money in coins is now put into the scale pan until it balances the article to be priced; the amount of money thus put in is the price of the article. An adjustable balance weight counterbalances the weight of the money scale pan. The machine we inspected, although arranged for the metric system of weights and measures, can be adapted to the British system without much difficulty.

THE UNITED STATES POST OFFICE.

Few persons, except those directly connected with the postal service in the United States, have a fair conception of the magnitude to which it has grown within the last few years. From the Report of the United States Postmaster-General for 1890, we learn that the United States leads all the world in the number of miles of railway postal routes. The combined length of the railway postal routes of the country is 144,557 miles, while the transportation of mails on those routes last year reached the enormous total of 186,575,384 miles. Germany comes next with a total length of 24,522 miles and a total transportation of 89,267,000 miles. But the railways by no means carry all the mails in the United States. The Star route and steamboat service have a length of 251,792 miles, with a transportation annually of over 12,000,000 miles. To carry on successfully this immense service requires the work of over 90,000 persons. The postal correspondence of the United States with foreign countries falls but a little below that of Germany, which leads the lists of nations. Ninety millions of pieces were despatched by the United States to foreign countries during the year 1890. When it is known that of the 90,000,000 pieces forwarded, fully 70,000,000 were carried by vessels of foreign register, the anxiety for some measure by which American mails can be carried by American vessels will be readily understood.

POSTAL RATES TO THE COLONIES AND BRITISH INDIA.

An interesting correspondence has recently taken place between Messrs. Maconochie Brothers, Lowestoft, and the Postmaster-General respecting the reduction of the postal rates to the Colonies and British India, This firm states that they are able to effect a large saving in postage by sending their price lists and circulars to Antwerp for transmission to India and Australia. The rates from the Continent to India for printed matter not exceeding 50 grammes (nearly 2oz.) is 5 centimes, or ½d., and to Australia, New Zealand, and other parts of the world 1d., whereas the rates from England to those places are 1½d. and 2d. respectively. The saving of postage on the sending of 20,000 circulars by despatching them from the Continent has been estimated at about £100. The new postal rates, which came into force on the 1st of January last, apply only to letters, and it is suggested that British firms should be allowed to send circulars from England to other parts of the Empire at rates as low as those available to competing foreign firms. A uniform ocean postage of ½d. for 2oz. of printed matter to the whole of the Empire would enable British firms to send their circulars direct from England. It is also stated that some firms send their letters in bulk to any one colony, to be afterwards distributed in that colony at a cost of 1d. for each letter. If a uniform "ocean postage" for letters of 1d. per ½oz. to all parts of the Empire were adopted the whole of this correspondence would be sent direct from England. The postal authorities state that the question of transit rates on trade circulars is to be discussed at the Postal Congress, which is to be held at Vienna this month, but that no immediate reduction can be made on the present postage rates. It is much to be wished that the discussion at the Postal Congress will render possible such a reduction as will give British firms facilities equal to those enjoyed by foreign firms for the transmission of printed circulars.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

18th April, 1891.

6256. Bow, W. ..... Riveting apparatus.
6263. Haddon & Clayton ..... Grate bars and apparatus connected with steam boiler furnaces.
6267. Monks & Bush ..... Movable signals on engines or trains.
6277. Stopford, T. R. ..... Apparatus for consuming smoke in stationary steam boiler flues.
6279. Pallister, E. A. ..... Apparatus for feeding letter-press printing machines.
6296. Lake, W. R. ..... Apparatus for burning liquid fuel (*The Stickney Oil Burner Company*).
6302. Stehlik, A. ..... Apparatus for moistening air.
6304. Barstow, Shaw, Crone, Jun., Taylor, & Shaw Boiler furnaces.
6812. Lloyd, R. S. (of the Firm of Hayward, Tyler, & Co.). ..... High pressure cocks or valves.
6320. Wirth, J. ..... Propelling apparatus for vessels.
6322. Stevens, N. P. ..... Plug and socket cutters and chucks for same. (22nd September, 1890.)
6324. Sébillot, A. M. G. ..... Ship railways.

14th April, 1891.

6334. Martignoni, J. ..... Tools for cutting, drilling, and grooving metals.
6338. Jackson & Hoad ..... Hydrostatic weighing machines, weighbridges, and the like.
6348. Crabtree, J. ..... Sand moulding machines.
6352. Williams, J. ..... A steam wheel as a motor to drive machinery.
6353. Brewer, W. J. ..... Antifriction bearing wheels for revolving axles.
6360. Shaw & Harcourt ..... Coils employed in clutches, brakes, and the like.
6362. Carter, J. E. ..... Nut and set screw turning lathes.
6365. Gass, W. G. ..... Single-acting steam engines.
6368. Boult, A. J. ..... Air brake and signalling apparatus for railway trains (*Mason*).
6369. Thompson, W. P. ..... Horseshoe machines (*Carrington, Morris, & Bucklin*).
6375. Megill, E. L. ..... Gripper fingers for platen printing presses.
6390. Johnson, A. ..... Apparatus for communicating motion eccentrically for tool-holder for lathes, &c.
6392. Lunkenheimer, E. ..... Straight way valves.
6393. Lawrence & Ranyard... Method of examining and recording the condition of steam boilers and removing scale and sediment therefrom.
6406. Clark, A. M. ..... Mechanism for threading wires through pipes or tubes (*Wessel & Giese*).
6408. Boggett, W. ..... Means for heating water to a high temperature for producing steam.
6410. Day, J. ..... Gas engines.

15th April, 1891.

6423. Andrew, W. ..... Boilers used in the manufacture of paper pulp.
6429. Hartley, J. W. ..... Cold sawing machines.
6432. Stopford, Kilroe, Wallbank, & Johnson..... ..... Smoke consumer for locomotive and other boilers.
6434. Madeley, F. ..... Manufacture of cased tubing.
6435. Wilson, T. W. ..... Jacquard machines.
6436. Thompson, J. A..... A method of condensing steam or other fluids.
6437. Schofield & Ashworth Carding engines.
6439. Sykes, T. ..... Fuel economisers.
6451. Holbrook, W. ..... Disintegrators.
6457. Vosper, C. W. ..... Method for working multiple spindles for various purposes.
6478. Tillcock & Conning ... Oval and circular cutting machine.
6482. Bonne, C. R. ..... Dredging apparatus (*Lentz*).
6483. Von Kiester, A. ..... Pumps.
6490. Ritter, A. B. ..... The manufacture of bolts and rivets.
6497. Riemer, J. ..... Apparatus for rolling tubes, tubular rods, and cylinders.
6503. Lüthy, O ..... Shuttle-driving mechanisms.

16th April, 1891.

6507. Rymer-Jones & Westray Apparatus for heating air previous to its being forced through the furnaces of steam boilers.
6510. Sanderson & Hood ..... Feeding steam boilers.
6511. Hartcliffe, W. ..... Full way valves or stopcocks.
6520. Brown, A. F. G. ..... Sight feed lubricators.
6528. Common, A. A. ..... Method of and apparatus for determining the time of flight of projectiles.
6530. Shaw, E. A. ..... Apparatus for pulverising minerals.
6535. Weston, R. ..... Railway signalling.
6541. McNaughton, J. A. ..... Air and vapour engines.
6547. Wood, J. ..... Gas regulator or governor.
6573. Pochin, W. ..... Rotary motors and pumps.
6574. Bousfield, J. E. ..... Apparatus for indicating the names of stations in railway carriages (*Schlösser*).
6578. Barclay, A. ..... Gas engines.
6596. Gehre, M. ..... Multitubular steam boilers.

17th April, 1891.

6598. Ridealgh & Welford ... Gas or vapour engines.
6600. Green, S. ..... Carding engines.
6601. Smith & Smith ..... Apparatus for washing and scouring wool and other fibres.
6605. Smith & Drysdale ..... Machine for bending chain links.
6608. Slade, E. A. ..... The propulsion of closed buoys or tubular boats or rafts by hand power.
6615. Green, F. S. ..... Igniter tubes for gas engines.
6620. Eynon & Seaman ..... Manufacture of piles or billets for rolling mills. (29th September, 1890.)
6622. Soulerin, L. ..... Railway brakes worked by fluid pressure.
6643. Barker & Woodcock ... Apparatus for the production of gas and hot air for marine boiler and other furnaces.

18th April, 1891.

6669. Miller, I. T. ..... Rock drill.
6671. Gildemeister, F. ..... Drilling machines.
6673. Thomas, F. ..... Screw propellers of steamships.
6675. Thompson, J. ..... Slubbing intermediate and roving frames.
6678. Horrocks, J. ..... Combined safety and anti-vacuum valve.
6686. McArthur, A. ..... Steam boiler and other furnaces.
6696. Covert, D'E. S. ..... Alarm for steam generators (*Ashley*).
6702. Whiteley, J. ..... Cotton spinning machines.
6703. Syddall, S. ..... Adjustable travelling clearer roller for spinning machinery.
6717. Abel, C. D. ..... Apparatus for supplying oil and other liquids under a constant pressure (*The Gas Motoren Fabrik Deutz*).
6718. Casciaro, A. M. ..... Apparatus for registering the number of passengers and distance travelled by same in vehicles.
6726. Petit, C. ..... Cocks or valves.
6727. Van Rennes, D. W. ..... Petroleum engines.
6734. Weston, R. ..... Railway signalling.

ELECTRICITY.

13th April, 1891.

6276. Blanchard, G. W. ..... Electric locking devices for the gear wheels of motors of electric cars.
6292. Miller, H. W. ..... Electrical insulator.
6298. Wodicka, J. ..... Armatures of dynamo electric machines.

14th April, 1891.

6347. Tugwell & Mitchell ... Alternating current transformers.
6378. Van Depoele, C. J. ..... Electric motors.
6402. Collier, A. T. ..... Microphonic or telephonic transmitters.

15th April, 1891.

6485. Gravier, A. I. ..... Dynamo-electric and electro-dynamic machines.

16th April, 1891.

6517. Dorman & Smith ..... Electric light switches.

17th April, 1891.

6633. Teague, F. ..... Electric meters.
6660. De Ferranti, S. Z. ..... Distribution of electrical energy.

18th April, 1891.

6730. Mordey, W. M. ..... Dynamo-electric machines.

CHEMISTRY.

13th April, 1891.

6268. Dawson & Hirsch ..... Raw materials for production of colouring matters.

14th April, 1891.

6376. Brooke, Simpson, & Spiller, Ld., & Green The production of new bases and of azo-colouring matters therefrom.
6387. Heyes, W. ..... Apparatus for concentrating acids and other liquids.

15th April, 1891.

6415. D'Andria, M. N. ..... Utilising waste acid residues from the "pickling" of iron.
6479. Rickard, W. T. ..... The mechanical and chemico-metallurgical treatment of copper and other ores.
6500. Kolb, J. ..... Production of chlorine.
6502. Von der Poppenburg, J. Galvanic batteries.

16th April, 1891.

6509. Wilson & Harvey ..... Manufacture of ferric chloride from waste pickle.

MISCELLANEOUS.

18th April, 1891.

6253. Warneford & Turner Locking nuts on bolts.
6288. Gummer & Gummer ..... Tap valves.
6303. Darby, J. H. ..... Manufacture of steel.
6323. Taussig, E. ..... Apparatus for smelting and casting.
6326. Bousfield, J. E. ..... Locks (*Piddington*).

14th April, 1891.

6350. Mansfield, L. ..... Means for preventing loosening of the keys or wedges in the chairs of railway rails.
6377. Eyre, C. J. ..... A new motive power.
6380. Brewer & King ..... Axle lubricators.
6395. Jones, F. G. ..... Joint for soil and like pipes.
6399. Bauer, F. ..... Glands for stuffing boxes.
6400. Bowring, H. E. ..... Boats' davits.
6411. Baumotte, H. ..... Manufacture of chisel and other like cutting tools.

15th April, 1891.

6414. Phillips, H. L. ..... The manufacture of spanners or wrenches.
6430. Rayner, J. ..... Safety lamps.
6464. Munns, W. H. ..... Vehicle wheel (*Jeffery*).
6466. Munns, W. H. ..... Wrench (*Perault*).

16th April, 1891.

6529. Day, J. M. ..... Bolts and nuts with locking device.
6548. Wood & Brookfield ... Motive power.
6564. Liardet & Liardet ..... Chain shackles and lowering hooks and tackles.
6579. Hill, E. J. ..... Boat lowering tackle.
6588. Miller, E. C. .... Loose pulley lubricators (*Miller*).
6590. Walsh, T. H. ..... Car couplers. (25th September 1890.)

17th April, 1891.

6631. Ruthven-Murray, E. T Ratchet braces.
6632. Boutcher, A. G. ..... Socket or collar for stoneware drain pipes, traps, gullies, &c.
6645. Wilton & Wilton..... Furnaces.
6658. Johnson, J. Y. ..... Lubricators (*Plisson*).

18th April, 1891.

6683. White, R. J. ..... The manufacture of white lead.
6737. Billups, J. E. ..... Permanent way for railways and tramways.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1890.

2202. Westwood & Butler.
4226. Peyton.
5560. Whitehouse.
5616. Fraser.
5781. Keller & Keller.
5917. Mackie.
6083. Gordon.
6238. Pallister.
6285. Turner, Bayliff, & Bayliff.
6557. Oertel.
6644. Johnston & Johnston.
6726. Von Hefner-Altenbeck.
7058. Johnson (*Marx & Weller*).
7215. Allport.
7372. Brockas & Irving.
7491. Birch.
7614. Hogg.
7659A. Rutter. (16th May, 1890.)
7791. Brining & Lister.
7842. Hines, Howell, & Howell.
7981. Sechehaye.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Slide Valves.—*W. C. Church, London.*—In the valve under notice the working fluid is admitted through the middle of the cylinder facing into the interior of the slide valve, and the exhaust is discharged into the slide jacket outside the slide valve, but obviously the working fluid might be admitted by a passage in the cover of the slide case. Double-ported slides have within the body of the slide exhaust passages opening into the jacket, and operate in conjunction with exhaust ports, which alternate with the admission ports. On the upper side of the slide valve is fitted a cap, which travels with it, but which has a slight extent of free motion on an internal spring ring, the edges of which and of the interior of the cap are slightly oblique or rounded to allow a little accommodation of the valve to the working faces. The areas pressed upon by the supply and exhaust fluid are so proportioned that the pressures towards the cover nearly balance the pressures towards the face. A spring is provided between the cap and the valve, which keeps both bearing on their working faces. Chases or grooves are formed in the working faces to allow the escape of leakage fluid, and the said faces should be arranged so that the slide and cap over-pass in their travel the edges of the stationary surfaces against which they work. For large size valves a central tie-bolt, or pair of tie-bolts, are provided to pass through an opening in the slide valve to secure the slide jacket cover to the cylinder. Claims: A slide valve having an internal cavity supplied with working fluid and constituting a central port; a valve having a middle port and two end ports governing double ports for each end of the cylinder, and having in connection with the cavity eduction passages opening into the slide case; the cap, spring ring, and arrangement of the forms and dimensions of rubbing surfaces, so as to obtain an approximately balanced valve.—No. 7187. May 8th, 1890. 1*s.* 1*d.*

Finishing Machines.—*J. Kirk & B. Lee, both of Leeds.*—The invention relates to machinery for finishing worsted, woollen, and other woven fabrics. Such a machine is shown in the annexed illustrations, of which Fig. 1 is a side elevation, Fig. 2

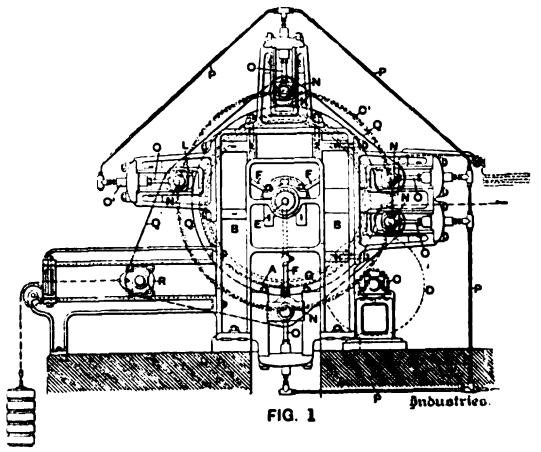

FIG. 1

a front part sectional elevation, and Fig. 3 an enlarged detail. The main cylinder A, which is journaled in suitable framework B, and driven by gearing C C¹ from D, is double rimmed, having an annular space between the two rims. The trunnions of A are hollow, and have connected to them steam supply and exhaust pipes E, governed by valve E¹ (Fig. 3), by means of which steam is supplied to and exhausted from the inner chamber in A. Pipes F, provided with taps, are also connected to pipes E, and are connected with the annular space G between the two rims of A. These pipes F are principally for forcing water of condensation out of G, which receives its main supply of steam through pipes H, governed by suitable taps from the inner chamber in A, which chamber may be cooled by water supplied through pipe F¹. Around A are pressing rollers I, J, K, L, and M, the sliding bearings N of all of which are pressed towards the main cylinder A by the hydraulic rams O of the cylinders O¹, supplied with water under pressure through pipes P. An end-

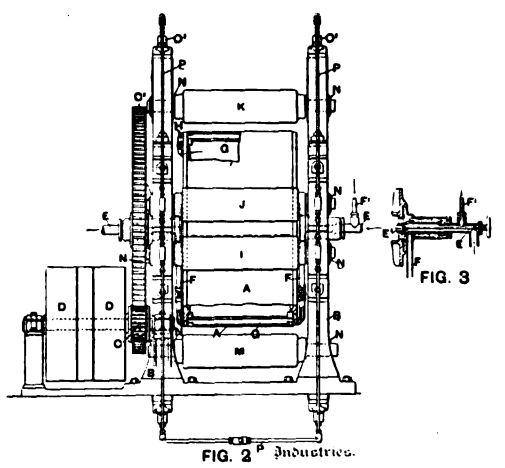

FIG. 2

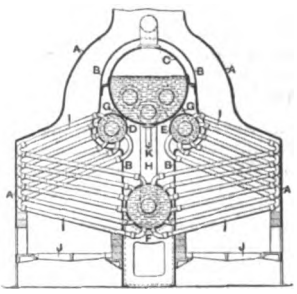

FIG. 3

less strap Q of thin metal, woven wire or other suitable material, passes partly around A, and then passes around the rollers I and J and the outside of K, L, and M and around a weighted sliding or tightening roller R. The outer wall of A may be perforated to allow of the steaming of the fabric being pressed. Five claims are made, embracing the general construction of finishing machinery as described.—No. 6258. April 24th, 1890. 8*d.*

Oil Motor Engines.—*O. Weiss, Köln-Nippes, Germany.*—An oil motor is described, together with an improved method of producing the combustible gaseous charges from petroleum or other oil. The said method consists mainly in causing a portion of the burning combustible charge in the engine cylinder, at the moment of the greatest development of pressure and heat, to effect the conversion of the oil required for the next combustible charge into vapour, which is at once utilised in the engine. This is effected by an injector apparatus, which, being supplied with the said portion of highly heated gas, draws in liquid oil, and by means of the great heat of the gas converts it first into spray and finally into combustible vapour. The injector is supplied with the hot gases by a valve, which is spring-loaded to some pressure slightly less than the maximum pressure obtaining in the cylinder during combustion; this valve lifts as the point of maximum pressure is approached, and admits a small charge to the injector, which operates as above stated, and delivers the resulting vapour into a reservoir from which the engine draws its supply. The engines described, as operated by this arrangement, consist of one or more four-cycle engines, whose series of cycles (where more than one engine is used) overlap in a manner well understood. Claims: The method of producing combustible vapour by means of an injector supplied with hot gas at a high pressure and operating as described, in conjunction with a spring-loaded valve; the oil motor, consisting of two double-acting or four single-acting cylinders, one cylinder operating the injector to provide charge for another cylinder, and so on, in turn.—No. 3261. February 23rd, 1891. 8*d.*

Joint for Metallic Pipes.—*J. Aird, Tipton.*—As a substitute for the screw coupling of metallic pipes or tubes the following arrangement is devised, which is said to be less costly to produce, easier to connect, and capable of withstanding greater pressure than other connections:—On the exterior of each of the meeting ends of the two sections of pipe to be connected together a broad flange or collar is formed, and a groove may be made in the meeting faces of each of the flanges to receive asbestos or other packing. Upon each section of the tube a loose clamping collar is placed, which takes abutment against the back of the flange on the tube, and around the clamping collars holes or slots are formed for the reception of headed screw-bolts by means of which the parts may be drawn together. One of the clamping collars is formed with an annular flange thereon, which covers the joint formed by the meeting faces of the tube flanges and renders it impossible to blow out the packing, and the other clamping collar is formed to receive the flange of its neighbour so as to form a broad bearing or guide for the parts when screwed up, the packing being compressed in the operation, as may be readily understood. Claims: The flanged pipes with clamping collars, substantially as described, and the particular details arranged as described.—No. 16896. October 23rd, 1890. 8*d.*

Multitubular Boilers.—*J. M. Stratton, London.*—The object of the inventor is to obtain a large heating surface and rapid circulation. A boiler for this purpose is shown in the annexed illustrations, of which Fig. 1 is a transverse section, and Fig. 2 is a front elevation partly in section. In the centre of the combustion chamber A is a second chamber B, in which are placed the four cylindrical water chambers C, D, E, and F. The three chambers C, D, and E are connected by means of the tubes G, and the two, C and F, are connected by tube H. The lower

FIG. 1.

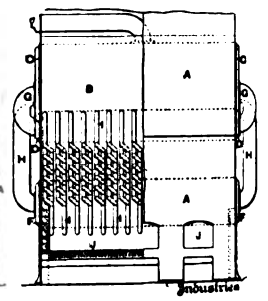

FIG. 2.

three chambers D, E, and F are connected by a number of clusters of smaller valve tubes I, which extend through each side of B across the double fire-grate J. The water is supplied to the upper chamber C through pipe K. Five claims are made embracing the boiler above described together with modifications.—No. 5633. April 14th, 1890. 11*d.*

Railway Couplings.—*H. Lacy, Middleton, Lancashire.*—This is a coupling apparatus arranged so that it may be operated by a steam or vacuum arrangement, or operated by hand without the necessity for going between the vehicles. Two horizontal shafts are arranged transversely at the end of the carriage in suitable bearings, one shaft carrying a pair of hooks and being on the level of the buffers, the other shaft being above the buffers; each shaft carries a spur wheel, and a vertical rack in gear with the said wheels gears the two shafts together. A detent is provided for the purpose of securing the gear in any position in which it may be placed. It is intended that the two hooks shall have their points downwards so as to lower into a pair of eyes on the opposite carriage. Presumably, the arrangement is fitted at one end only of each carriage. Claims: The coupling arrangement substantially as described, operated by hand, steam, or vacuum.—No. 6318. April 25th, 1890. 6*d.*

Gas Engines.—*E. & F. J. Seage, Exeter.*—In engines constructed according to this invention instead of employing the usual arrangement of valve shaft driven by bevel gearing from the crank shaft at half the speed of the latter, cams are attached to the boss of a spur wheel driven at half the speed of the crank shaft by a spur pinion thereon, and rocking levers extend from beneath the cams to a point beneath the valve chambers, being pivoted at about the centre of their length in such a manner that in addition to the oscillation in a vertical plane imparted to the levers by the cams, one of them may also receive a lateral oscillation when actuated by a link, which is controlled by the governor so that upon an increase in the speed of the engine that end of the valve lever which operates the admission valve, although continuing to rise and fall vertically, will be laterally moved out of the line of the spindle of the gas valve, which it will not operate, until, by the consequent reduction of speed, the governor brings it back into line with the valve spindle, when a tongue on the rocking arm will strike a projection formed upon the valve spindle, lifting the valve and readmitting the gas or combustible vapour to the cylinder. Claims: The use of suitably operated levers lying at right angles with the crank shaft for operating the admission and exhaust valves; a lever laterally oscillated by the governor, and controlling the admission valve, as described.—No. 8431. May 31st, 1890. 8*d.*

Digitized by Google

FURNACES, &c.—*G. Moffatt & S. Stuttaford, both of London.*—The particular arrangements covered under this invention are means for consuming smoke and economising fuel, so designed as to occupy but little room in the furnace, and therefore suitable for use in boilers of the locomotive type. A frame is fitted horizontally across the forward end of the firebox at about the level of the bars (which are preferably shortened by the length of this frame), which frame supports vertical tubes arranged in single or double rows across the firebox at the tube-plate end. The lower ends of the tubes are open, and air from below the fire-bars can obtain access thereto through the supporting frame, admission being regulated by a hinged adjustable door. It is preferred to make the tubes of greater width, measured across the firebox, than their width measured in the line of the bars, and the tubes are also preferably tapered, their lower ends being the larger; they terminate above the fuel in the firebox and are protected from flame by a firebrick casing in which channels are formed by which the air is led from the upper ends of the air tubes in thin streams to mingle with the hot gases rising from the fire on the way to the tubes. Claims: The combination of tubes, air door frame, and brick-facing as described.—No. 8168. May 24th, 1890. 8*d.*

FORGING MACHINES.—*R. Low, Clapham, Surrey.*—The machine embraced by this invention is for the purpose of rolling forgings of a circular or other form. The machine shown in the annexed illustrations, of which Fig. 1 is a side elevation and Fig. 2 a

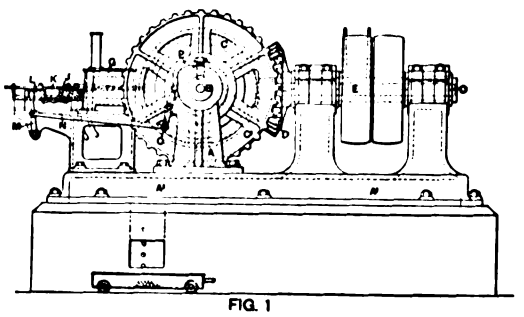

FIG. 1

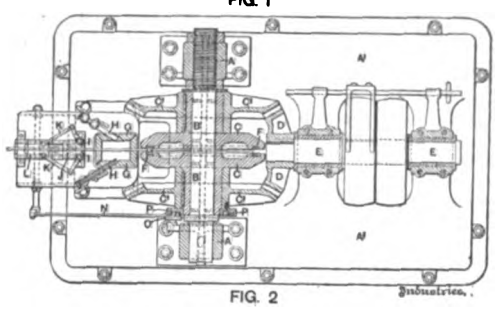

FIG. 2

sectional plan, is for the purpose of rolling spherical forgings. Mounted adjustably in supports A on base A^1 is a stationary rod B carrying upon it the two die holders C driven in opposite directions by means of gear C^1 on the hubs thereof and gear D on the driving shaft E. The dies F are formed in segments and are placed in grooves in the opposite faces of the holders C, which grooves are dovetailed, except in one part, where they are rectangular, to allow of the insertion of said segments. These dies are so formed that at one side of the holder there is a sufficient space to allow the rod from which the forging is made to be inserted. The faces, however, gradually converge towards one another until they touch (the various stages of the operation being plainly shown in Fig. 3). The bar to be operated upon is heated as it passes through a chamber C by means of burners H, and is advanced intermittently by means of gripping jaws or levers I pivoted on a slide J and connected by rods K to a second slide L receiving a reciprocating motion by rods M, N, O, and P on one

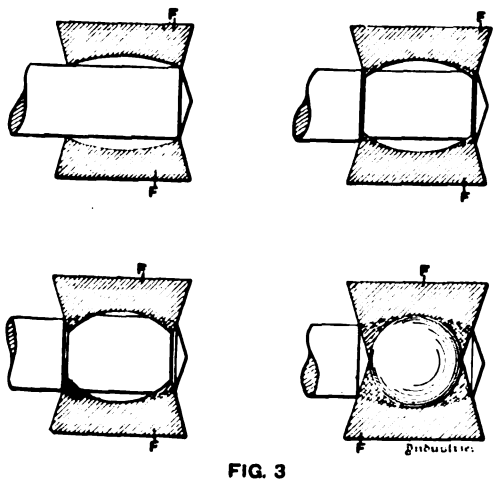

FIG. 3

of the wheels C^1. These slides are connected together by suitable bolts, but in such a manner that the actuating slide is moved a certain distance in one or the other direction before the other slide moves with it, so as to allow the grippers to grip or release the bar. Eight claims are made.—No. 6894. May 3rd, 1890. 8*d.*

VACUUM PUMPS.—*A. Berrenberg & Nickerson, both of Somerville, Mass., U.S.A.*—This invention consists in forcing into the cylinder of vacuum pumps at each suction stroke of the piston a quantity of oil from which air has been eliminated, this oil serving to fill all the clearance when the piston is at the extreme end of its stroke, thus permitting all air to be expelled. All excess of oil at the end of the stroke is forced out of the cylinder into a vacuum tank, in which any air that may have been taken into the oil during the forcing stroke of the piston will be withdrawn and the oil made ready for use again in the cylinder, this circulation and de-aëration taking place at each stroke of the piston. An arrangement of the apparatus is described wherein the reservoir of oil is in communication with a de-aërating cylinder, and, by another passage, in communication with the cylinder of the vacuum pump to which the apparatus is applied. The pump draws in during one stroke air from the vessel which it is exhausting, and also oil from the reservoir, and during the return stroke expels the air and the excess of oil together, the former passing freely away and the latter being led into a receiving chamber provided with a float valve regulating the return of the air to the reservoir. The oil feed-pipe is provided with a circulating pipe and a relief valve which prevents more than a certain pressure being put upon the oil supplied to the cylinder. Claims: Filling the clearances of a vacuum pump with de-aërated oil, as described.—No. 3352. February 24th, 1891. 6*d.*

HOT WATER SUPPLY BOILER.—*C. J. Jones, London.*—This boiler, which is intended for supplying boiling water under light pressure, is constructed as described in a prior patent, No. 13952 of 1884, and is heated from a gas burner as shown in the annexed illustrations, of which Fig. 1 is a vertical section of the boiler, Fig. 3 a plan of the gas burner A, and Fig. 2 an enlarged vertical section of the regulator valve. This regulator valve, which regulates the supply of gas to the burner A according to the pressure in the boiler, is constructed as follows:—B is a chamber covered at the top by a flexible diaphragm C, D is a second diaphragm separated from it by a ring E^3. F are screws by which a cover G is drawn towards the chamber so as to clamp the outer edges of the diaphragms and the ring E between them. E^1 is a hole formed through the ring in order that if the upper diaphragm becomes defective any water passing through it may escape outwards and not subject the lower diaphragm to pressure. G^1 is a pipe passing from the top of the cover G to the water space of the boiler. H is a filling block between the two diaphragms, and I a valve fixed to the underside of the lower diaphragm, and which, when this diaphragm is pressed downwards, comes against and closes the top of a tube J which rises up into the gas chamber B. The tube is continued downwards for a distance, and has within it a coiled spring K, which, pressed against a disc

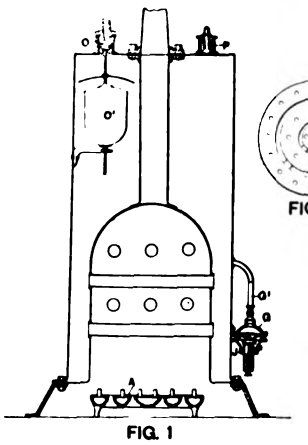

FIG. 1

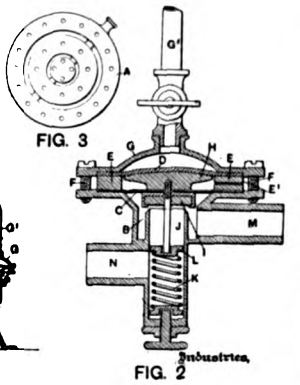

FIG. 2

L connected to the valve I, tends to keep the latter open. M is a pipe connected to the gas supply and N a pipe connected to the burner, the supply to the latter being governed, as described, by valve I. A valve O governed by a float O^1 is provided to regulate the supply of water to the boiler. P is a safety valve. Eight claims are made.—No. 4320. March 19th, 1890. 8*d.*

SMOKE PREVENTION.—*G. Moffatt & S. Stuttaford, London.*—For the purpose of consuming the smoke given off by the fuel in the furnaces of steam boilers the inventors provide a hollow casting forming a bridge, and situated as is customary in the flue, and at the rear end of the fire-grate. A partition extends downward from the rear end of the bridge and closes the lower half of the flue, preventing the admission of air from the ashpit directly into the flue, and causing it to ascend into and pass through vertical passages formed in the bridge, going out at the surface of the crown of the same into the space left between the bridge crown and the top of the flue, where it crosses the path of the furnace gases and mingles with them for the purpose aforesaid. The admission of air into the bridge passages is controlled by a hinged flap pivoted below them and operated from the front of the boiler. A firebrick facing is provided on the front of the bridge to preserve the bridge casting from the direct attack of flame, and holes for the transmission of heat extend through that portion of the casting into one of the air chambers. In the hollow spaces of the casting between the air passages are chambers, which communicate with the water space of the boiler and assist in heating its contents. Claims: The general arrangement, and the particular modification described, including the firebrick facing and holes at the rear thereof in the face of the bridge.—No. 8167. May 24th, 1890. 8*d.*

FORGINGS.—*H. Erhardt, Düsseldorf.*—According to this invention hollow forgings in iron or steel are made from solid blocks of red hot or white hot iron or steel. Several examples of the process are described, from which the following are selected:—To produce a hollow cylinder a piece of hot square metal is taken, the cross section of which, diagonally measured, corresponds to the diameter of the hollow cylinder to be produced, and is placed in a matrix, the inner cavity of which corresponds to the shape of the cylinder to be produced, and a pointed core bar is then driven into the metal by means of a hammer or press, the lid of the matrix forming a guide for the core bar. When desired, the matrices may be formed with jackets in which circulates a cooling medium. The metal is thus forced to fill the cylindrical matrix, and has an opening through its centre in the direction of its length. Hollow prismatic bodies may be produced in similar fashion, an important condition in all cases being that the metal to be operated upon shall be truly centred by the matrix. For hollow bodies of unusual length two core bars may be employed, entered into the metal from opposite ends. Where steam hammers or presses are used, their frames may form guides for the matrix. Claims: The process of simultaneous punching and shaping as described; also the matrix with cooling spaces.—No. 3116. February 20th, 1891. 6*d.*

ROTARY ENGINES.—*W. P. Thompson, London.* (*C. Bornet, Paris, France.*)—A rotary engine, such as embraced by this invention, is shown in the annexed illustrations, of which Fig. 1 is a transverse vertical section, and Fig. 2 a longitudinal section. Journaled eccentrically in the end plates of the cylinder A is the

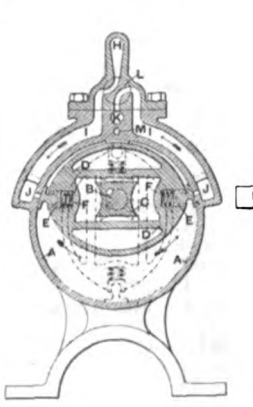

FIG. 1.

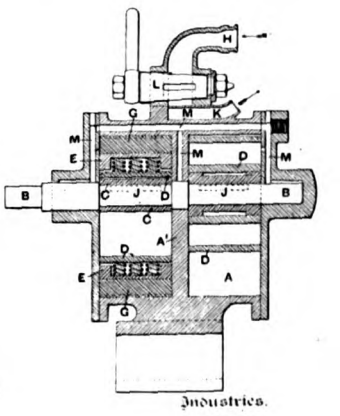

FIG. 2.

main driving shaft B carrying two blocks C, on which slide the two pistons D placed at right angles to one another and working in separate compartments in A formed by means of a division A^1. The exterior form of the pistons is determined by joining two arcs of a circle of a radius approximately equal to that of the interior of the cylinder. The ends of the pistons are furnished with recesses, in which slide the blocks E pressed forward by springs F, and fitted with joint slides G, the contact faces of which are bored cylindrically to the diameter of the cylinder. The motive fluid is supplied through pipe H, one of the circumferential passages I and ports J, the exhaust escaping through the other port and passage to outlet K. The direction of the motive fluid, and so the direction of the engine, is governed by three-way cock L. The passages M are for the supply of lubricant to the axle bearings. Three claims are made.—No. 7508. May 14th, 1890. 8*d.*

WATER TUBE BOILER.—*C. J. Galloway & J. H. Beckwith, both of Manchester.*—The inventors' object is to prevent the violent commotion of the water in water tube boilers caused by rapid circulation and to effect the better cleaning of the water tubes. Fig. 1 of the accompanying illustrations is a longitudinal section, and Fig. 2 is an end view of a boiler embodying this invention. From the fire A the flames and hot products of combustion are caused by baffle plates B to take a zigzag course between the tubes as indicated by the arrows to the flue leading to the chimney. At the top of the front water casing C where it communicates with the steam and water chamber D are formed between inclined diverging plates E a number of expanding passages dividing the currents of mixed steam and water that ascend from C, gradually retarding the divided streams and allowing the steam to separate quietly therefrom. At the top of the passage by which the rear water casing F communicates with the chamber D is provided a part G raised above the bottom of D so that impurities may become deposited in the quiescent water below without descending by G to F; these impurities may from time to time be cleared out by opening a

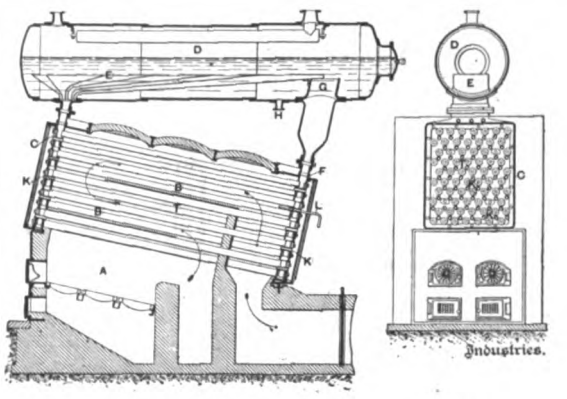

FIG. 1.

FIG. 2.

blow-off cock or valve applied at H. The stays K of the water chambers C and F are tubular, and preferably so placed that there is one between every three of the tubes T, as shown in Fig. 2. Usually these tubular stays are closed by plugs or covers, or some of them may be left open for admission of air to promote combustion. For the purpose of clearing soot off the tubes T is introduced through any of the tubular stays K a nozzle L connected by a flexible tube to a steam pipe, so that a jet of steam can be directed along the surface of the tubes within range of the jet, thus sweeping off the matters adhering to them. Claim: A water tube boiler, having tubular stays for its water chambers, having a set of divided expanding passages for the current ascending from the higher water chamber, and having the mouth of the passage from the lower water chamber raised above the bottom of the upper chamber, for the purposes set forth.—No. 7929. May 22nd, 1890. 8*d.*

Digitized by Google

GAS ENGINES.—*F. W. Lanchester, London.*—The invention embraces improved means of starting engines of the Otto type. Referring to the annexed illustrations, Fig. 1 is a cross section of a cylinder of a gas engine showing the arrangement for the above purpose, Figs. 2 and 3 being enlarged details thereof. The end of the cylinder A is fitted with an attachment consisting of a valve box B of a stop cock C, through which communication is made between the cylinder and valve box of a valve D, which normally remains open by its own weight, but is automatically closed by pressure in the engine cylinder, and of a nozzle E, which is connected to the valve box and opens to an external flame F. The nozzle E is conical, expanding towards the direction of discharge. The external flame F can be adjusted with reference to the nozzle E, and is supplied with gas by means

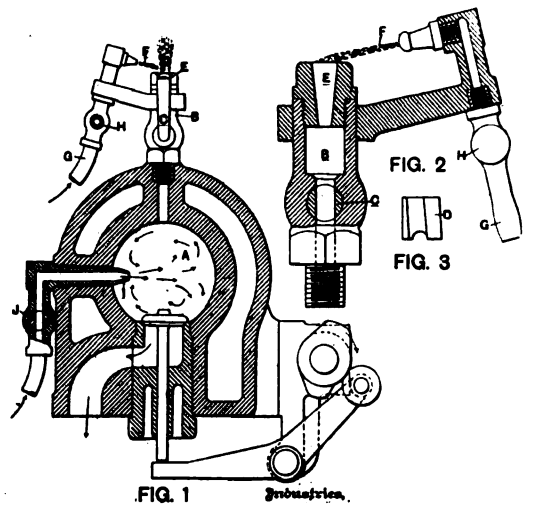

FIG. 1

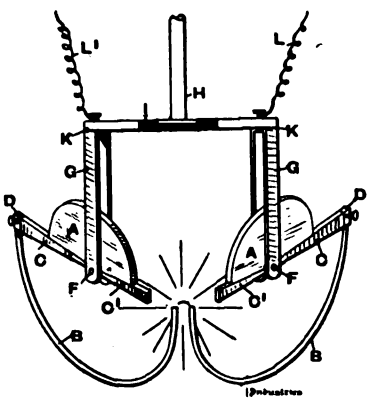

FIG. 2

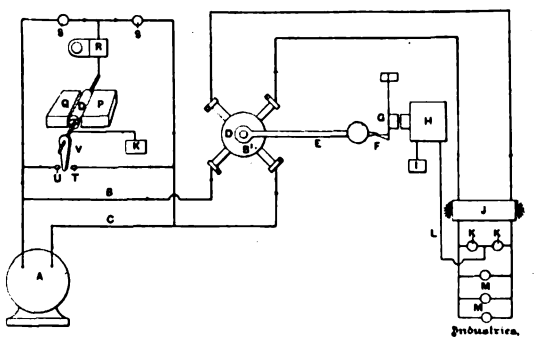
FIG. 3

of a tube connected to the nipple G. A stop cock H serves to regulate or extinguish the flame F. A is also fitted with a suitable nozzle I, through which gas can be admitted to the cylinder through the supply cock J. The gas so admitted may be forced in by the ordinary pressure in the gas supply pipes as illustrated in the cross section (Fig. 1). In order to start an engine fitted with the starter, it is placed so that its crank is somewhat over the in-centre of the working stroke; the external flame F is lighted, and the gas turned on to the working cylinder through L. The pressure in the gas pipes causes the gas to flow into the cylinder and displace a portion of the air it contains through E, but the entering jet mixes with the remaining air and so produces an explosive mixture, part of which, after a time, finds its way through E; F then ignites it, and the jet burns at E through the external flame into the atmosphere, increasing in richness of gas or vapour till explosive mixture is formed. J is then shut off, and the flame passes back into the cylinder and ignites or explodes the charge to increase its pressure to start the engine. The automatic valve D in the starter closes immediately on the explosion of the charge, and then the cock C is turned to put it out of action, when the engine continues to work in the ordinary manner. Three claims are made, embracing the device as described, with modifications.—No. 5479. April 10th, 1890. 8*d.*

ELECTRICITY.



ARC LAMPS.—*S. Capilleri, of Grasse, C. Kurmeyer, J. Goldberg, & R. Latzko, all of Vienna.*—This invention relates chiefly to an entirely novel method of constructing the carbons, which are each combined with a semicircular disc and are rotatable round a horizontal axis, and are made to act in accordance with the law

of archimedean spirals, whereby the free end of the carbon is caused, on burning away, to be always maintained in the same position relatively to the other carbon by turning on its axis. In the annexed illustration is shown an elevation of a lamp with such carbons. The disc A, made of any suitable material, is connected to the semicircular carbon B by an arm C having a clamp D in which the carbon B is fixed. The weight of the arm C is balanced by a counterweight C¹ in order not to interfere with the equilibrium of the spiral, and the whole is mounted on a horizontal axis F carried by a pendant bracket G. Two such transformed archimedean spirals with their brackets are fixed to a suitable support H, and are so arranged that when the lamp is not in action the carbons are in contact, but when in action the carbons are kept the proper distance apart. For this purpose one of the brackets G is mounted on a pivot at its connection at K with the support H, and has an arm fixed to it which carries the armature of an electromagnet in a shunt to the lamp circuit, the said arm acting as the weight for bringing the carbons together. The support H is divided by an insulating piece I into two parts, each of which is connected to one of the leads L L¹ of the circuit. The current entering at L passes through H, bracket G, axis F, and arm C to the carbon B, thence to the other carbon B, arm C, axis F, bracket G, and support H to the lead L¹. Claims: The lamp as described, in two claims.—No. 5409. April 9th, 1890. 8*d.*

ELECTRICAL ALARM FOR PUMPS.—*E. Hartmann, Düsseldorf.*—This appliance is designed to put the driving power of a pump out of action upon any undesirable lowering of the water level owing to accumulations of air, or to other causes; or it may be arranged simply to give warning of the fact that the pump has stopped working. The pump communicates with a casing in which there is a perforated float which rises or falls with the rise or fall of the water level. In the lowest position of the float (which is reached before any accumulation of air or occurrence of vacuum can take place to any dangerous extent) a circuit is closed whereby an audible signal may be given, or whereby a brake or a throttle valve may be operated. The leads may be carried into the float chamber in an adjustable tube, and their separated ends, if sufficiently far apart, will not be electrically bridged together by the liquid in that chamber. Or, to achieve the same results in a manner well known to electricians, the float may be caused to open a circuit which is normally closed. In another modification the float when commencing to sink opens an air valve, which will accelerate its sinking—thus immediate warning of any small variation in working conditions may be given. Claims: The general arrangement of apparatus substantially as described.—No. 6865. May 3rd, 1890. 8*d.*

TRANSFORMERS.—*J. Swinburne, Wimbledon, Surrey.*—The inventor's object is to render an installation supplied by a transformer safe from risks of fire or danger, by earthing the middle of the secondary circuit through a fine fuse or cut-out, so that if a current passes through the fuse or cut-out the primary circuit is automatically disconnected from the whole system. An arrangement of this description is shown diagrammatically in the accompanying illustration, in which A represents the central station dynamo, B and C the high-pressure mains, J a house transformer, and D is a double-pole switch in the primary circuit. M M are lamps on the secondary circuit. K K are two resistance or choking coils, between which an earth connection L is arranged, communicating with the earth plate I. A current along L actuates the electromagnet H, thus attracting the armature G and

releasing the catch F; the weighted lever E then drops, catches on the pin B¹ and opens the switch, thus disconnecting the transformer altogether. If the leak is on one of the secondary leads nothing further happens, but if between the primary and secondary leads there will be a current at the station through the earth plate K to the armature of a piece of apparatus which puts that lead to earth and rings a bell. The apparatus thus protects both high and low pressure circuits from danger, and gives notice of any fault. Claims: In connection with a transformer the use of the automatic leak finder as described, and in an open circuit transformer a cross-shaped or equivalent backbone; insulating a transformer by placing it in a vessel of insulating material.—No. 3193. February 28th, 1890. 8*d.*

SWITCHES.—*S. F. Beevor, London.*—To protect the contact surfaces and other metallic parts of switches and contact breakers from corrosion, and to prevent loss of current or other evil results which might be produced by contact with surrounding bodies, the metallic parts as aforesaid are enclosed in a flexible or collapsible waterproof envelope of insulating material, one end of which is attached to the part which carries one of the two contacts, the other end being attached to the part carrying the remaining contact. Several switches arranged according to this invention are described, in one of which two discs of insulating material are held apart by metal rods and are encased in a metal cylinder. Between these two discs is a third disc, free to rise and fall, and guided in such movement by the metal rods. This disc carries spring contacts, which engage with plugs standing out from the face of one of the fixed discs. Around the peripheries of all three discs are deep rings of insulating material connected to each other by flexible rings of indiarubber or other waterproof insulation, the joints between the discs and the rings being formed by vulcanising. A cruciform or other suitable partition, of one piece with the vulcanite base, is arranged to separate the contacts carried thereby, and interposes a resistance to prevent sparking between adjoining conductors. A torque switch and single and double lever rocking switches are described, all on the same general principle, which is claimed, as also are the particular examples shown.—No. 8477. May 31st, 1890. 8*d.*

RECORDING AND MEASURING APPARATUS.—*F. B. Lea, Streatham.*—The inventor states that in recording instruments as hitherto constructed it has been found that the friction of a point marking a paper or card is considerable, and sufficiently variable to render the records untrustworthy. In this invention a metallic point carried at the end of the arm of a lever caused to rise and fall in close proximity to a paper-carrying drum is heated to incandescence by a shunt circuit in the case of electrically measuring instruments, or by a current from a battery in the case of a recording barometer or the like. The heating of the point may be intermittent, in which case a make and break arrangement is operated by the clock-work which drives the paper-carrying drum, and the strip or coil of paper may be chemically prepared so that the mark may be produced by a lower degree of temperature than is requisite when ordinary paper is employed. The heated point is a substitute for the pencil or siphon recorder hitherto employed, the record being burned upon the paper without the point coming into actual contact therewith. Claims: A recording measuring instrument as described, and the method of heating the index or pointer continuously or intermittently. The use of this apparatus in combination with a recording telegraphic or signalling instrument is also claimed.—No. 7902. May 22nd, 1890. 8*d.*

CHEMISTRY.

THE OBTAINMENT OF CYANIDES AND FERROCYANIDES.—*D. J. Playfair, Glasgow.*—Cyanides and ferrocyanides are obtained from sulphocyanates or from bisulphide of carbon and ammonia, and the bye-products reconverted or otherwise utilised. Cyanides are obtained by heating together in a retort or crucible the sulphocyanate of an alkali or alkaline earth with lead or zinc or a mixture thereof, these metals having a strong affinity for sulphur and forming insoluble sulphides. Ground wood charcoal or other suitable carbon may be mixed with the charge of sulphocyanate and lead or zinc, or may be merely spread over so as to cover the top of the charge, or it may be dispensed with altogether. The carbon is not essential, its function being merely to maintain a reducing temperature within the retort or crucible, to prevent oxidation of the cyanide formed to cyanate, and to reduce to cyanide any cyanate accidentally formed by access of air to the charge or in consequence of any oxygen compounds of the lead or zinc being present. The lead or zinc may, in a state of fine division produced by granulation, be thoroughly incorporated with an equivalent weight of the dry alkaline sulphocyanate, so as to produce an intimate mixture before being charged into the crucible or retort. The charge is heated to a temperature somewhat above the melting point of zinc, whereupon a reaction takes place, resulting, when sulphocyanate of sodium is used, in the production of cyanide of sodium and sulphide of zinc. When ferrocyanides are required the process described is modified by replacing part of the lead or zinc with iron, in the form of borings, turnings, or other porous form. In the fusing process the iron is converted into sulphide along with the lead or zinc, but on subsequent lixiviation reacts with the alkaline cyanide, forming a ferrocyanide of the alkali which may be crystallised. The sulphocyanates employed may be obtained from the sulphocyanate of ammonia met with in "gas liquor" or "gas lime," or obtained from any other convenient source. It is, however, preferred to obtain the sulphocyanate by heating together in a closed vessel liquid ammonia and bisulphide of carbon along with a solution of a fixed alkali or alkaline earth (preferably as a hydrate, although either a carbonate or a sulphide may be used) or by mixing in a condenser or other suitable vessel the vapours of ammonia and bisulphide of carbon, or by passing the vapour of one into the other in a liquid state, and adding a solution of the fixed alkali. The resulting solution is heated in a still to drive off any free ammonia and sulphide of ammonia and any other ammoniacal compounds that may be present, the products so volatilised being collected in condensers or absorbers for further use. The solution of sulphocyanate of the fixed alkali remaining in the still is separated from precipitated sulphur by settling, decanting, and filtering, and is then evaporated to dryness and treated as hereinbefore described to obtain cyanides and ferrocyanides. Claims: (1) The process for obtaining cyanides by fusing a sulphocyanate of a fixed alkali or alkaline earth with lead or zinc or a mixture thereof, and subsequently separating the metallic sulphide formed, substantially as described; (2) the process for obtaining ferrocyanides by fusing a sulphocyanate of a fixed alkali or alkaline earth with lead or zinc in the presence of iron, subsequently lixiviating the mass and crystallising the ferrocyanide; (3) in combination with either of the processes claimed in the first and second claims, forming the sulphocyanate employed in any of the modes hereinbefore described and reconverting or utilising the metallic sulphides as described.—No. 7764. May 19th, 1890. 6*d.*

MISCELLANEOUS.

BOAT LOWERING GEAR.—*J. Stevens, Trenton, Michigan, & G. E. Beers, New York, U.S.A.*—In this arrangement of gear each end of the boat is upheld by a single rope, the upper end of which is made fast to the davit, the lower ends of the ropes being wound round on the drums of two windlasses, operating simultaneously to raise or lower, by means of a horizontal fore-and-aft connecting spindle. The said lower ends are formed with eyes which are passed over pins or projections on the windlass drums, so that when the said drums are allowed to unwind the ropes automatically disengage themselves from the boat by slipping over the pins. Winding apparatus is fitted at the centre of the horizontal shaft or spindle, and consists of a spur pinion operated by hand and gearing into a spur wheel with a pawl or detent, for the purpose of raising the boat. To lower the boat the spur pinion is put out of engagement with the spur wheel, and the ratchet wheel is released, a brake strap being operated to retard the rotation of a pulley, with which the spur wheel is connected. To prevent the boat from tipping each rope is taken as far down in the boat as is possible, and is led through the seats. Claims: Double windlasses, with a detachable winding mechanism; the horizontal shaft and detachable ropes; the power gear, releasable pinion and ratchet, with drums and brake gear; drums at the bottom of the boat, with bearings in the seats for the rope as described.—No. 3442. February 25th, 1891. 6*d.*

Copies of the British specifications may be obtained on application to* H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.

IMPROVED QUICK-RETURN SLOTTING MACHINE.

THE accompanying illustration represents a general view of a self-acting quick-return slotting machine, made by Messrs. Harry Bentley & Co., Excelsior Iron Works, Morley, near Leeds, which has a variable stroke up to 12in., and an adjustable feed motion for the longitudinal, transverse, and circular cuts. All the feed motions are fitted with friction clutches and act independently of each other. The table is hinged and fitted with an adjustable appliance for slotting taper keyways. The quick return motion is obtained by a pair of elliptical wheels, which the makers prefer to that obtained from the slotted link arrangement. The ram is provided with a heavy balance weight, which effectually prevents backlash and ensures steadiness of motion. The machine, which is of neat appearance, will admit work of 5ft. diameter and 2ft. high.

THE STRESSES IN BOILER SHELLS.

By J. H. SLADE, R.N.

THE following investigation was suggested by a consideration of the paper by Mr. Spence, published in *Industries*, of the 13th and 20th March,* and of the startling inferences there drawn, which are quite opposed to the present practice in boiler designing. The writer found on inquiry that these ideas as to the great support derivable from the ends were obtaining some currency in the North, and, not being aware of any previous attempt to show how to estimate, in a fairly simple manner, the values of the stresses produced, was led to inquire into them, the results obtained being set forth in the present article. For reasons set forth farther on, a full and complete investigation has not been carried through, but enough has been done to attain the end in view—viz., to show that our present practice is, for all practical purposes, perfectly correct.

We will now commence the investigation.

Let $2a$ = length of boiler,
r = radius,
t = thickness of shell plate,
t^1 = „ end plate.

Let the boiler be stayed, so that no longitudinal stress comes on the shell plates, and in accordance with the assumption in the paper referred to above, we will suppose that of the total pressure $P + p$ lbs. per square inch, p lbs. are transmitted to the end plates, leaving P lbs. to be borne by the circumferential tension. We will then try to find out what relation may exist between P and p.

The total loading is then divided into the two sets, shown in Figs. 1 and 2, of which that shown in Fig. 2 is supposed to be transferred by transverse stresses to the ends.

We will consider first the stresses produced by Fig. 2, and the first thing to note is that the reasoning adopted in Mr. Spence's appendix (see *Industries*, Vol. X., page 266), explaining how these stresses are transmitted to the ends, is fundamentally unsound. It is there stated that the stress is transmitted as a shear, which is true; but it is further stated that there is no bending, which is untrue. A B C D is spoken of as a beam, and any forces tending to bend the top are said to be balanced by equal forces tending to bend the bottom. Hence it is deduced there is no bending. This deduction is perfectly correct if we consider A B C D as a whole. There is no bending moment on it; *its axis* remains straight, and therefore it is not bent. But, then, this reasoning equally applies

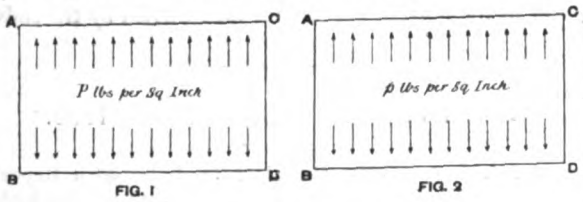

FIG. 1

FIG. 2

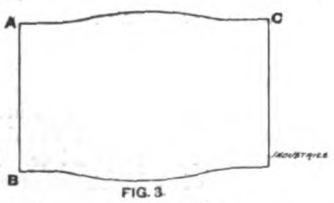

FIG. 3.

to shearing. As a whole, the beam A B C D neither shears nor bends; but, taking any longitudinal strip of the shell plate, this strip shears—which is the shearing referred to by Mr. Spence—and undoubtedly it also bends, for, if A B C D take up the shape shown in Fig. 3, evidently the originally straight top strip A C is now a bent strip.

It is important to clear up this point at the start, because, as will soon appear, the strains—*i.e.*, alterations of form—produced by the bending are far more important than those due to the shearing.

We will now examine the equilibrium of a longitudinal strip taken from Fig. 2, 1in. wide.

A C (Fig. 4, page 434) is the strip, the form it takes up under the action of the forces being shown by the dotted curve, called the curve of deflection; this is, of course, on an exaggerated scale. For the forces acting on the strip, we have its total length $2a$ inches and width 1in., so its area is $2a$ square inches, and the total load on it is hence $2pa$ lbs., whence we have at each end a supporting force of pa lbs. as shown. But the ends of the strip are more than simply supported, because they are riveted to the end plates and are thus held in a horizontal position, so that a double curvature is produced. To produce this effect the end plates must supply a resisting couple at each end in addition to the resisting force pa. These couples are marked M M.

Take now O X and O Y as axes, and take K any point on the deflection curve, its co-ordinates being x and y, then we have the general equation of deflection—

$$\text{E I} \cdot \frac{d^2y}{dx^2} = \text{the bending moment at K,}$$

$$= pa(a-x) - p(a-x)\frac{(a-x)}{2} - \text{M},$$

$$= \frac{p}{2}(a^2-x^2) - \text{M},$$

$$\therefore \text{E I}\,\frac{dy}{dx} = \frac{p}{2}\left(a^2x - \frac{x^3}{3}\right) - \text{M}x,$$

the integration constant vanishing, because when $x = 0$, dy/dx, or the slope, is also zero. Also $dy/dx = 0$ when $x = a$, since the ends are horizontal, whence—

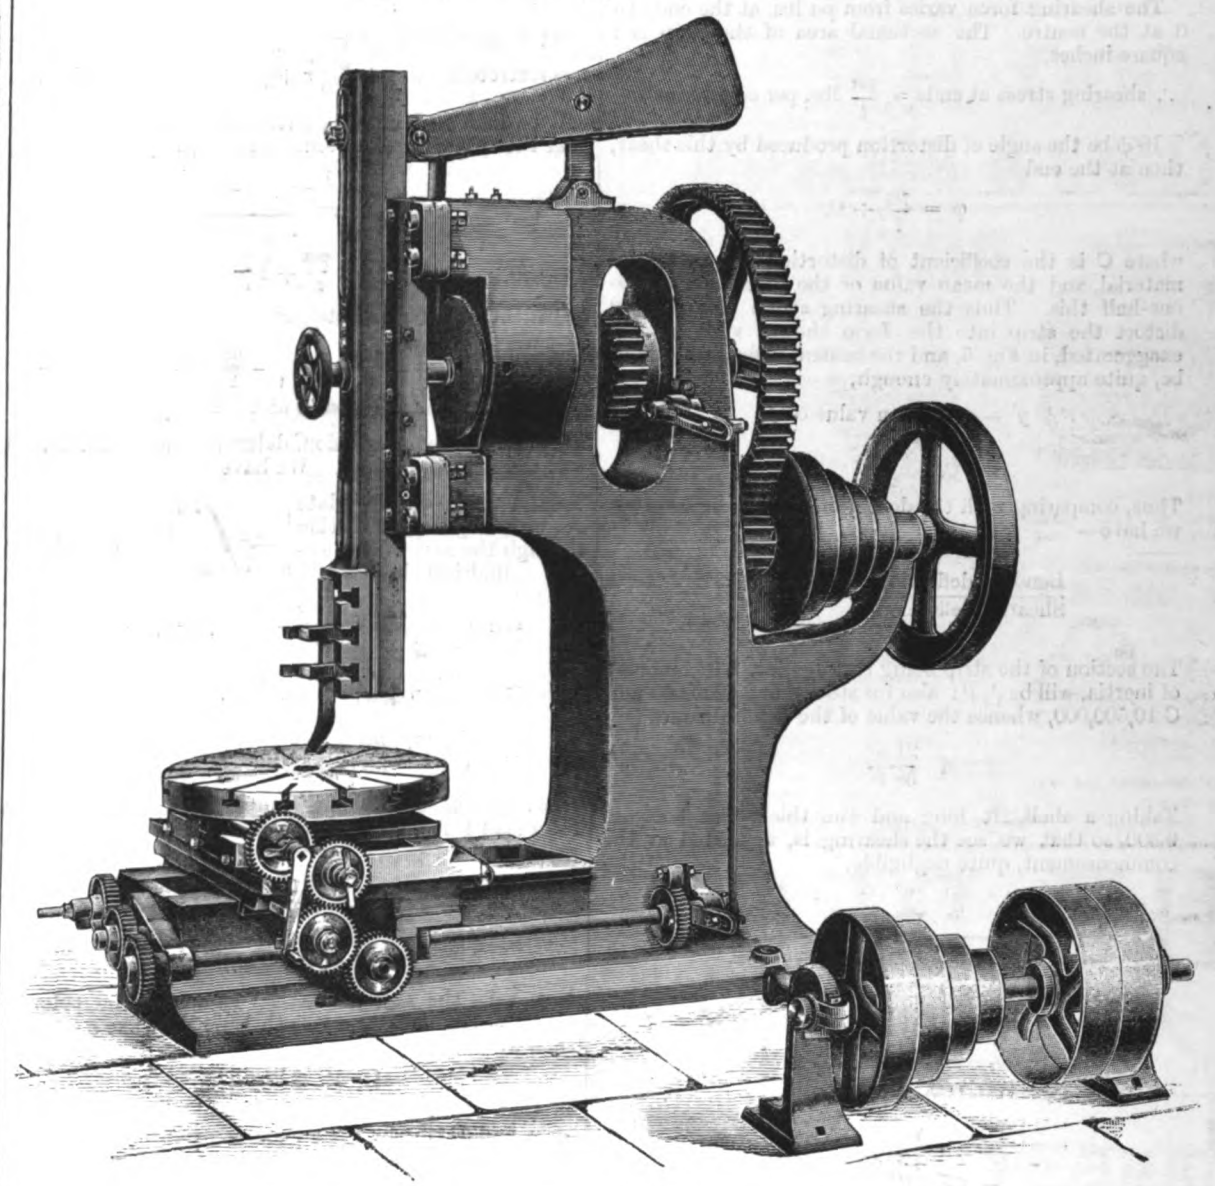
$$0 = \frac{p}{2}\left(a^3 - \frac{a^3}{3}\right) - \text{M}a,$$

$$\text{or } \text{M} = \frac{pa^2}{3},$$

$$\therefore \text{E I}\,\frac{dy}{dx} = \frac{p}{6}(a^2x - x^3),$$

$$\therefore \text{E I}\,y = \frac{p}{6}\left\{\frac{a^2}{2}(x^2-a^2) - \frac{x^4-a^4}{4}\right\}$$

this form being taken because it satisfies the condition $y = 0$ when $x = \pm a$.



The last equation, then, is the equation to the curve formed by the bent strip, which form will also be taken by all the other strips into which we may conceive the cylindrical shell to be divided.

* It is only fair to Mr. Slade to state that his article reached us several weeks ago, and has been held over owing to the pressure upon our space. —ED. *Industries*.

IMPROVED QUICK-RETURN SLOTTING MACHINE.

CONSTRUCTED BY MESSRS. HARRY BENTLEY & CO., ENGINEERS,

MORLEY, NEAR LEEDS.

GENERAL VIEW.

Digitized by Google

Before proceeding farther we will now show that practically the whole change of form produced is due, not to shearing, but to bending.

From the equation, the central deflection, say y_0, is given by

$$\mathrm{E\,I}\,y_0 = \frac{p}{6}\left\{-\frac{a^4}{2}+\frac{a^4}{4}\right\} = -\frac{pa^4}{24}$$

$$\therefore\ y_0 = -\frac{pa^4}{24\,\mathrm{E\,I}}.$$

We need not trouble about the sign, because the direction of the deflection is evident.

Now for shearing:

The shearing force varies from pa lbs. at the ends to 0 at the centre. The sectional area of the strip is t square inches,

$$\therefore \text{ shearing stress at ends} = \frac{pa}{t} \text{ lbs. per square inch.}$$

If ϕ be the angle of distortion produced by this shear, then at the end

$$\phi = \frac{pa}{t} \div \mathrm{C},$$

where C is the coefficient of distortion for the given material, and the mean value of the distortion will be one-half this. Thus the shearing stress alone would distort the strip into the form shown, very greatly exaggerated, in Fig. 5, and the central deflection y^1 will be, quite approximately enough,

$$y^1 = a \times \text{mean value of } \phi,$$

$$= \frac{pa^2}{2\,\mathrm{C}t}.$$

Thus, comparing with the deflection due to the bending, we have—

$$\frac{\text{Bending deflection}}{\text{Shearing deflection}} = \frac{\frac{pa^4}{24\,\mathrm{E\,I}}}{\frac{pa^2}{2\,\mathrm{C}t}}.$$

The section of the strip being rectangular, I, its moment of inertia, will be $\frac{1}{12}\,t^3$; also for steel E is 29,000,000 and C 10,500,000, whence the value of the ratio becomes

$$\frac{21\,a^2}{58\,t^2}$$

Taking a shell 2ft. long and $\frac{1}{4}$in. thick, this becomes 6,300, so that we see the shearing is, as stated at the commencement, quite negligible.

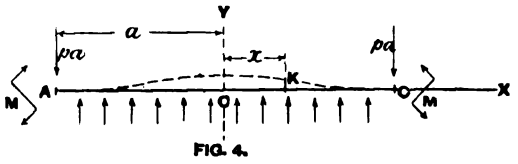


FIG. 4.

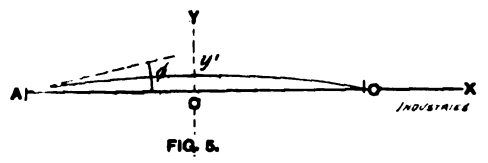

FIG. 5.

Next, we have to consider how this bending of the metal can be made consistent with the assumption that the remainder P of the load is carried by circumferential tension. We can see at once that our present assumption cannot hold in its entirety, for the bending necessitates that the central hoops or rings are more stressed than the end ones, since they are more stretched (Fig. 3, page 433) and stress is proportional to stretch. Thus, if the mean amount of the load borne by circumferential stress be P lbs., this will be more borne by the central hoops than by the end ones. But this reacts again, for it follows that less than p lbs. are left at the centre to be borne by the bending, and more than p lbs. at the ends; the effect of this being that the bending produced will be less, and the actual curve of deflection be intermediate between the curve of Fig. 4 and a straight line.

[It may be asked here whether the effects produced by these two sets of stresses may not modify each other, but fortunately they do not. The bending stresses have no resultant effect in the direction A C, and there is no alteration of length in A C, the difference between the length of the curve and the line being an indefinitely small quantity; thus, these stresses can produce no circumferential strain, and we are thus justified in taking this strain as being due simply to the accompanying stress round the circumference.]

In spite of the fact, however, that our original assumption is plainly inadmissible, we will continue with the calculation, seeing afterwards what modifications may become necessary.

We have now a load pa lbs. carried by every inch length of circumference of each end plate; thus, the thickness being t^1, the end plates are subject to a stress pa/t^1, and their radii will accordingly be increased from

r to $r + \frac{pa}{\mathrm{E}t^1}r$.

This will also be the radii of the end rings of the shell, and the radius of any other ring, say at K, will be got by adding the ordinate y of the deflection curve at that point to $r + \frac{pa}{\mathrm{E}t^1}r$.

At K, then, we have the ring, whose original diameter was r, stretched to $r + \frac{pa}{\mathrm{E}t^1}r + y$; and the circumference will be increased in the same ratio; whence it follows that the circumferential tension is given by

$$\mathrm{E}\left(\frac{r+\frac{pa}{\mathrm{E}t^1}r+y-r}{r}\right)$$

or

$$\frac{pa}{t^1}+\mathrm{E}\frac{y}{r}.$$

Substituting for y we get

$$\left.\begin{matrix}\text{Circumferential}\\ \text{tension at K}\end{matrix}\right\} = \frac{pa}{t^1}+\frac{p}{6r\mathrm{I}}\left\{-\frac{a^2}{2}(x^2-a^2)+\frac{x^4-a^4}{4}\right\}$$

(The sign is changed so as to make y positive).

We can now, by integration, determine what total load this tension will balance. We have

$$\left.\begin{matrix}\text{Total tension on the plate}\\ \text{cut by a longitudinal section}\\ \text{through the axis of the cy-}\\ \text{lindrical shell}\end{matrix}\right\} = 2\int_0^a\left(\frac{pa}{t^1}+\frac{\mathrm{E}y}{r}\right)2t.dx$$

$$= 4t\int_0^a\left\{\frac{pa}{t^1}dx+\frac{p}{6r\mathrm{I}}\left(-\frac{a^2x^2}{2}+\frac{x^4}{4}+\frac{a^4}{4}\right)dx\right\}$$

$$= 4t\left\{\frac{pa^2}{t^1}+\frac{p}{6r\mathrm{I}}\left(-\frac{a^5}{6}+\frac{a^5}{20}+\frac{a^4}{4}\right)\right\}$$

$$= 4t\left\{\frac{pa^2}{t^1}+\frac{pa^5}{45r\mathrm{I}}\right\}$$

Now, if this is sufficient, on the whole, to balance a total load P lbs. per square inch over the whole surface, we get

$$\mathrm{P}\times 2a\times 2r = 4t\left\{\frac{pa^2}{t^1}+\frac{pa^5}{45r\mathrm{I}}\right\}$$

$$\therefore \mathrm{P} = \frac{t}{r}\left\{\frac{pa}{t^1}+\frac{12pa^4}{45r^3}\right\} \text{ substituting for I.}$$

Now, take the same numerical values we did before—viz., a = 1ft., and t and t^1 both $\frac{1}{4}$in.; also take r = 1ft.—then we obtain

$$\mathrm{P} = 615p,$$

so that $\frac{1}{616}$th of the pressure would be borne by the ends, and $\frac{615}{616}$ths by the circumferential tension.

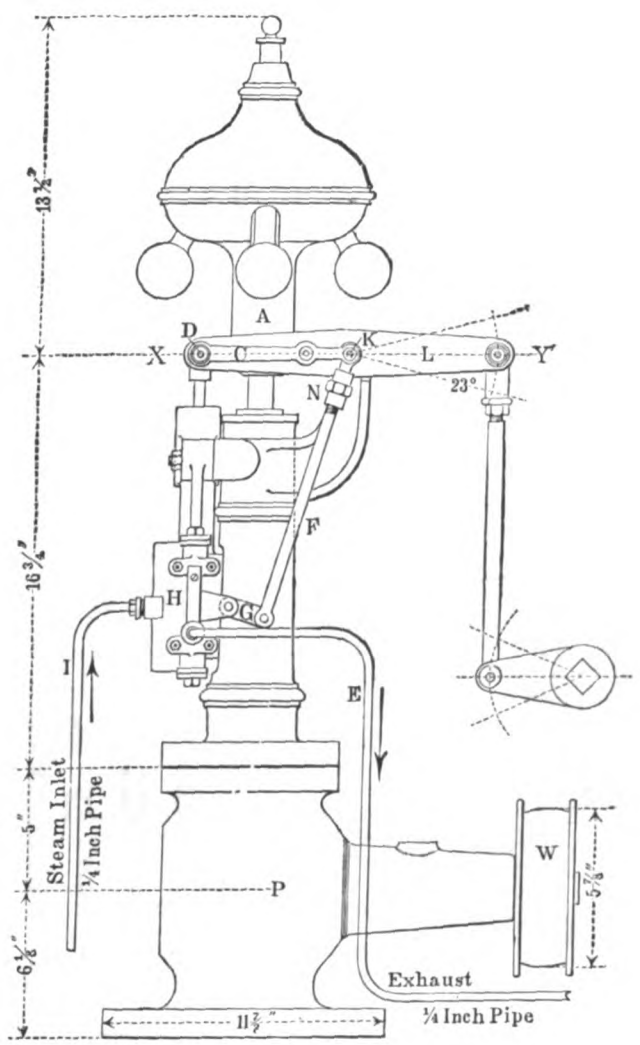
The reason is now apparent why we did not go on to make some fresh assumption as to the distribution of the portion of the load transmitted to the ends, when we had seen that our first assumption was not a consistent one. For example, it might have been assumed that the loading in Fig. 2 varied uniformly from the centre to the ends, and a solution worked out on this assumption, which would necessarily have been nearer the truth. But on first examining the question, the above work had been got out to its numerical end, and it was then apparent that it was not worth while going through the labour of examining other assumptions. Taking the above case, what we see is that the bending produced by transmitting $\frac{1}{616}$th of the load, supposed uniformly distributed, to the ends, added to the slight extension of the ends produced by this $\frac{1}{616}$, this sufficient to produce such alterations of the radii as to balance the remaining $\frac{615}{616}$ths by the usual tension. If now we commence by taking off $\frac{1}{616}$th of the load at the centre, and take off more as we go towards the ends, then we should bend the beam more than shown in Fig. 4, and also we should increase the radii of the ends by more than in our preceding; but this will not do, because then the circumferential tensions produced would be more than sufficient to balance the remaining load, which would be less than $\frac{615}{616}$ths of the total. It follows then that we must not assume so much as $\frac{1}{616}$th taken off at the centre, and this at once settles the whole question, for it follows that the plates at the centre must be made thick enough to take the whole, practically, of the load by simple tension—that is, that our present method of determining the thickness of shell plates is perfectly correct.

As regards what the actual distribution of the part of the load transferred to the end plate is, we can get a fair idea by considering that at the end the rings can only extend the same amount as the end plates, and thus a very large amount of the load on the extreme rings must be transferred to the ends; this amount will, however, rapidly fall off, and will have practically vanished at a distance, say, of about 2in. or 3in., from the ends of a shell such as we have considered.

It will be seen that the conclusion here arrived at is directly opposed to those drawn in the paper we have referred to, and it may be asked how can this be reconciled with the facts there given, because if theory—which some may be inclined to call the foregoing work—comes into contact with facts, it must give way. There is, however, no difficulty of that kind in the present case if the facts be rightly read. First, it must be noticed the preceding investigation refers to stresses inside the elastic limit; a great field of research lies open in considering the behaviour of metals outside this limit, but it is sound practice now, and is likely to remain so, not to expose structures to stresses outside their elastic strength; hence the limitation in this respect of the investigation does not detract from its value, if any. Now one principal difficulty in these experiments appears to be that circles near the end seem by the measurements there given to stretch more than those at the centre, which hardly agrees with our investigation, but on examination it seems most highly probable that these are accidental effects, and not the effect of any definite law. This especially applies to the abnormal results at the joints; if these represented a law there would be a regularity about them as the pressure increased; but we see no sign of any such a thing—the contractions appear suddenly, remain constant for varying loads, and then suddenly alter sign for no apparent reason. A similar statement to the foregoing also appears applicable to the stretching of the solid metal given—*e.g.*, No. 5, Table I., page 243. At 350 an extension of $\frac{1}{32}$ appears, which remains constant up to 500, and then at 550 doubles, and so on. Such alterations as these are such as would be expected from original deviations from a true cylindrical shape, to which the form of joint chosen contributed, for any form of lap joint necessarily implies distortion.

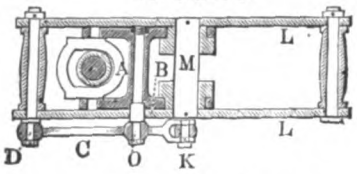
One result of the experiments also appears to have been overlooked, and one which has rather an important bearing, for, judging from the drawings given, the actual end plates did not stretch in the least. It appears strange that this should not have been noticed, for, if they carry such a large proportion of the load, how do they manage to avoid stretching? The same thing applies to the sketch given of Mr. Scott's boiler.

The only other result requiring explanation is the great load borne by the boilers, but this again can be accounted for by reference to known facts. The breaking load of the steel used is given at 28·3 tons per square inch, but this load is per square inch of the *original section* of the test pieces, which, it is presumed, were so constructed as to admit of a uniform stretching taking place over some 8in. or 10in. of their length. These pieces, it is seen by the Table given, contracted in area to about 60 per cent. of the original, so that the actual tenacity of the metal across the break becomes 47 tons per square inch. Now breaking through a riveted joint is one of those cases in which contraction of area is suppressed, the broken section being practically equal to the original, and in such cases it is known that the strength of the metal would approach very nearly to the 47 tons; and hence the explanation of the apparent great strength of the boiler.

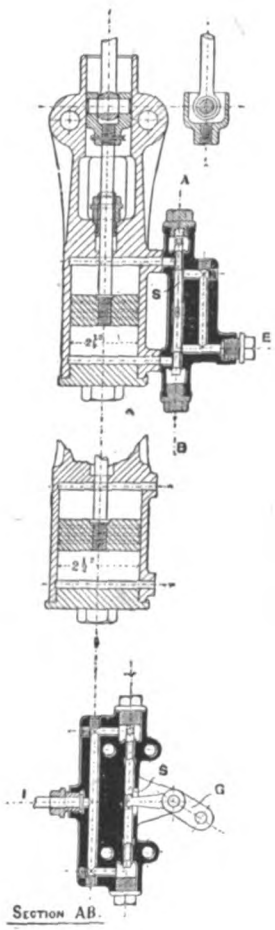


The final conclusion appears to be that the whole of the facts are susceptible of explanation according to known principles, and that it would be highly dangerous for any one to make boiler shells half the present thickness in the hope of getting the load carried by the ends.

RAILWAY ACCIDENTS IN 1890.



A few days ago the Board of Trade issued a Report containing a complete record of the railway accidents that occurred during 1890, taking into account not only collisions, but also all other causes of death or disablement. The deaths amounted to 1,135, and the number of the injured to 11,568. But from these numbers it is only right to make considerable deductions when inquiring into accidents for which the direct working of the railways can be held responsible. For instance a considerable number of accidents occurred in endeavouring to catch trains, in loading and unloading waggons, and attending to horses, and in working on the line. From these causes there were 59 deaths, and 6,847 injuries, which makes the figures due to the working of the traffic and passengers almost exactly the same as for the previous year. But again, for these the companies cannot be held responsible for a considerable proportion, for many of them were brought about by causes within the control of those who suffered. For example 250 were



Digitized by Google

STEAM ENGINE GOVERNORS.

Section X-Y.

Section AB.

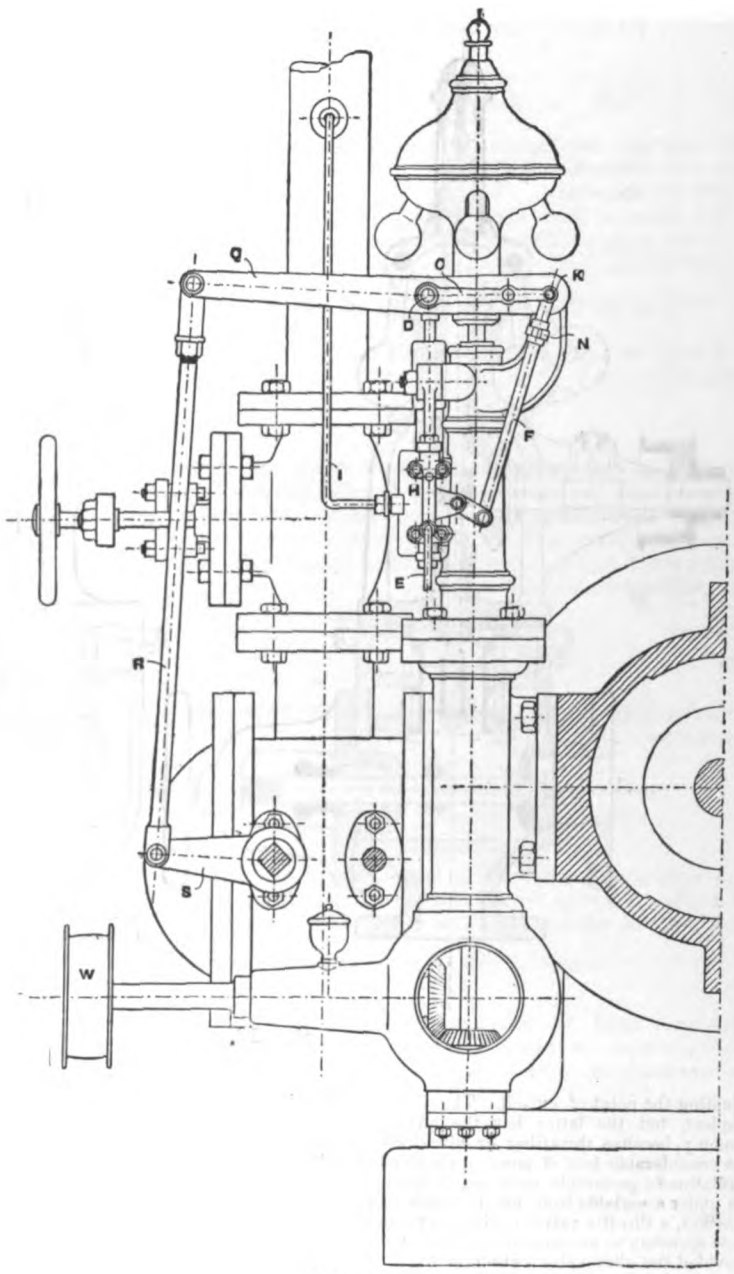


Fig. 10.

Fig. 11.

killed when trespassing on lines, and were almost as much to blame as the 70 who are reported to have committed suicide. Nearly 100 died from injuries received at level crossings, and between 20 and 30 from attempting to enter trains or to leave them before they had stopped.

When all deductions of this kind are made it is found that only 30 persons were killed—18 passengers and 12 servants of companies—from causes beyond their control. The comparison with 1889 is as follows :—

	1890. Killed.	Injured.		1889. Killed.	Injured.
Passengers	18	496	...	88	1,016
Servants of companies	12	147	...	4	117
Totals	30	643	...	92	1,133

A large proportion of the death-rate in both these years is accounted for by special disasters, and not by accidents in the ordinary working of the lines. In 1889 the Armagh disaster swelled the roll, while for last year, if the two accidents at Carlisle Station and the one at Norton Fitzwarren were put aside, it will be seen that the number of casualties which may be classified as preventible is very small indeed. This is very satisfactory, and is due in great part to the forethought and care of the railway managers and other officials, aided, no doubt, to a very considerable extent, by the inspecting officers of the Board of Trade. A bad accident is one of the worst things which can happen to railway companies, for not only do they pay very heavily for it directly in the way of damages, but also indirectly by loss of traffic. The Board of Trade inspectors do good service by the investigations they hold, and the suggestions they offer for the improvement of the arrangements for the traffic. They also promote the public safety by directing attention to the long hours which many railway servants have to work, and pointing out that a great strain on the drivers, guards, signalmen, and others cannot conduce either to the interests of the companies or to the safety of the travelling public. It is satisfactory to find that both public and official opinion is advancing on this subject, and that there is now a fair prospect of all the more serious grievances being removed.

STEAM ENGINE GOVERNORS.*

(*Continued from page* 412.)

In the application of governors for actuating heavy valve gears, it frequently becomes a matter of difficulty to obtain sufficient sensitiveness and power combined, and this circumstance has militated against the use of gears such as the Rider and Meyer gears which, in point of simplicity and efficiency, are second to none other. They are substantial and positive, and are therefore also available at the highest speeds, and if well designed, excellent diagrams can be obtained from engines fitted with this class of gear, but the force required to move the valve gear is considerable and necessitates too great a variation of speed even if a very powerful governor is employed. Various auxiliary appliances for augmenting the power have therefore been introduced, and of these one of the most ingenious and successful is that invented by Lüde, and shown in Figs. 10 and 11. In this governor the only work of the governor proper consists in controlling the piston valve of a miniature steam engine, the piston rod of which is connected with the expansion slide. By the use of an exceedingly ingenious combination of levers, the motion of the piston and connections is caused to correspond precisely with that of the governor, and even with a very slight variation of load, the expansion valve is moved over a corresponding distance with the full steam pressure. For Rider and similar gears, a cylinder having a diameter of 1½in. is employed, and with a pressure of 75lb. per square inch this will exert a force amounting to about 120lb. If applied to Corliss gears, the cylinder is made 2in. or 2½in. diameter, and the corresponding force exerted at the same pressure amounts to 230lb. or 320lb.

Referring to Fig. 10, the motion of the governor muff A is transmitted by means of the double lever B to the lever C which is pivoted at D in the main lever L. The short arm of the lever C is connected by means of the rod F to a small lever G which actuates a ¾in. equilibrium piston valve arranged in the casing H on one side of the steam cylinder. This valve controls the steam admission and exhaust ports of both cylinder ends, the arrangement being such that both sides of the piston are connected with the exhaust pipe E when the valve occupies its normal central position, while a very small displacement of the valve in either direction permits of steam entering one end of the cylinder. The resulting motion of the main piston rod and lever L with connections causes the piston valve to return to its central position so as to again open both sides of the piston to the exhaust, when the lever L has been turned through an angle corresponding to the displacement of the governor muff. Normally the centre of the joint K corresponds with the turning axis of the lever L. When the governor muff is displaced, the lever C is caused to turn about the centre D, thereby raising or lowering the centre K. The resulting displacement of the lever L causes the lever C to turn about the centre O, and the centre K is consequently returned into agreement with the axis M of the lever L. It is therefore evident that the motion of the lever L and connections will always correspond precisely to the motion of the governor muff, and owing to the high velocity of steam this action is practically instantaneous. The diameter of the steam supply and exhaust pipes should be ¾in. The work of the governor proper is almost *nil*, and consists only in overcoming the friction of the distributing valve or spindle in its guide. The friction of this is very small, as there are no stuffing boxes or other packings, and the movement of the valve is less than 1/32in. Owing to the smallness of the "work" of the governor proper, the wear of the parts connected with the governor—that is, the distributing valve and the small levers—is also quite insignificant. Fig. 11 shows one method of fitting this governor to an engine with Rider gear.

A governor can be applied to actuate either a throttle valve, so as to vary the *pressure* of steam on the engine, or a variable expansion gear to vary the *volume* of steam by automatically

* Paper read before the Manchester Association of Engineers on the 11th ult., by Mr. C. F. Budenberg, M.Sc.

STEAM ENGINE GOVERNORS.

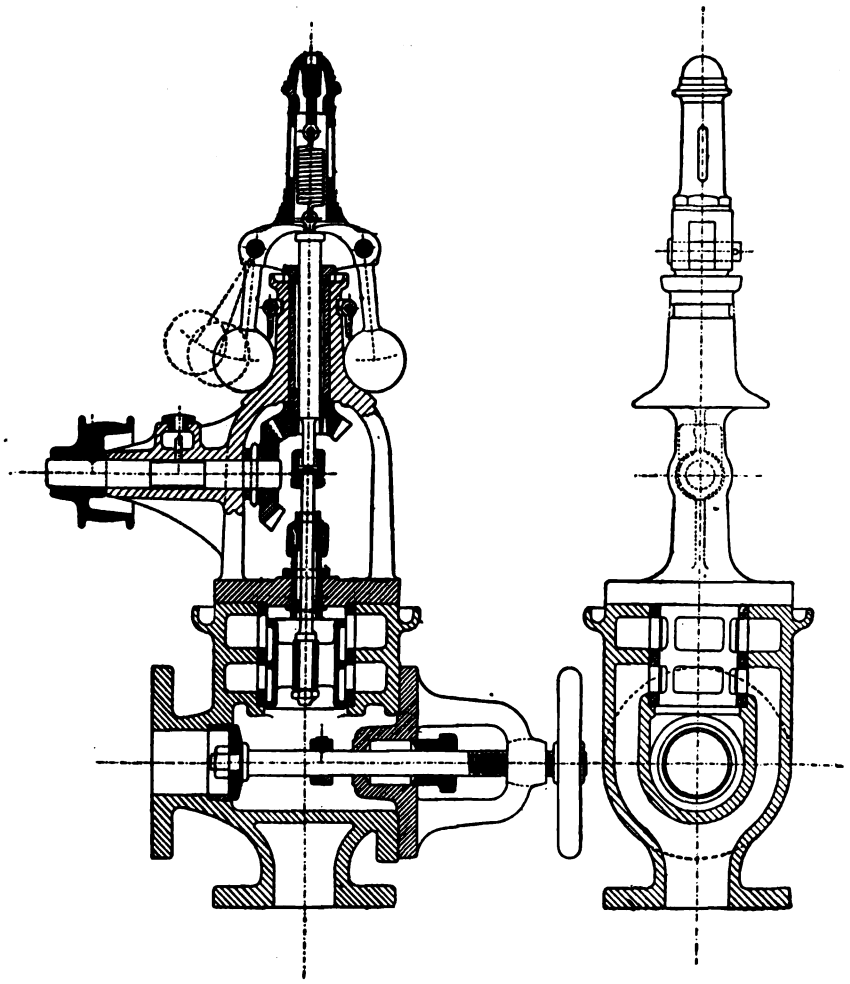

Fig. 12.

adjusting the point of cut-off. The former system is by far the simplest, but the latter has the advantage of greater steam economy, because throttling or wire-drawing the steam results in a considerable loss of power. Generally speaking, expansive regulation is preferable, more especially in large engines working under a variable load, but in cases where the load is nearly constant, a throttle valve engine may work with practically the same economy as an expansion engine under similar conditions, provided the slide valve cut-off is fixed, so that with the maximum load on the engine the pressure obtained in the cylinder falls little short of the boiler pressure.

No hard and fast rule can be laid down regarding the relative advantages of the two methods of regulation, and each case must be considered separately with a due regard to all surrounding conditions, but it must be remembered that both in first cost and in maintenance the throttle valve is by far the cheaper, and although many would have us believe the contrary, there are conditions under which a throttle valve is preferable to any expansion gear. With regard to uniformity of speed, there is nothing to choose between the two systems, as this depends entirely upon the sensitiveness and power of the governor and upon the resistance of the valve or gear.

In the early days of the steam engine, the pivoted disc throttle valve was employed, but this has now been superseded by various cylindrical equilibrium valves, which offer a far smaller resistance, and, therefore, allow of a greater uniformity of speed than the disc valve. The governor and throttle valve is generally combined to form a self-contained fitting, and the manufacture of these has become a specialty, the engine builder being thus relieved of the difficulty of suitably combining governor and valve. Fig. 12 shows a combination of this description, and represents the Soho governor as made by Messrs. Tangyes, Limited, of Birmingham. Similarly, Fig. 13 shows the Buss governor as made by Messrs. Schäffer & Budenberg, of Manchester. These governors, being fixed upon the valve, a long drive is required to work the governor, and strap driving is generally resorted to instead of positive wheel driving.

Although not as reliable as wheels, strap-driving has the advantage that any change of speed is not suddenly transmitted to the governor. Nevertheless, the strap should be fairly stiff, so as not to be materially affected in length when a change of speed takes place, and, above all, it must be perfectly even. Various ingenious appliances have been invented for automatically closing the throttle valve and bringing the engine to a stop in case the strap should give way, but some engineers employ multiple rope driving by which the chance of any such occurrence is practically put out of the question. Some makers employ an ordinary mushroom valve as throttle valve, but this construction is decidedly objectionable, because it offers too great a resistance, and also because it cannot close completely, and is, therefore, not always sure to check the engine when the load is taken off completely.

(To be continued.)

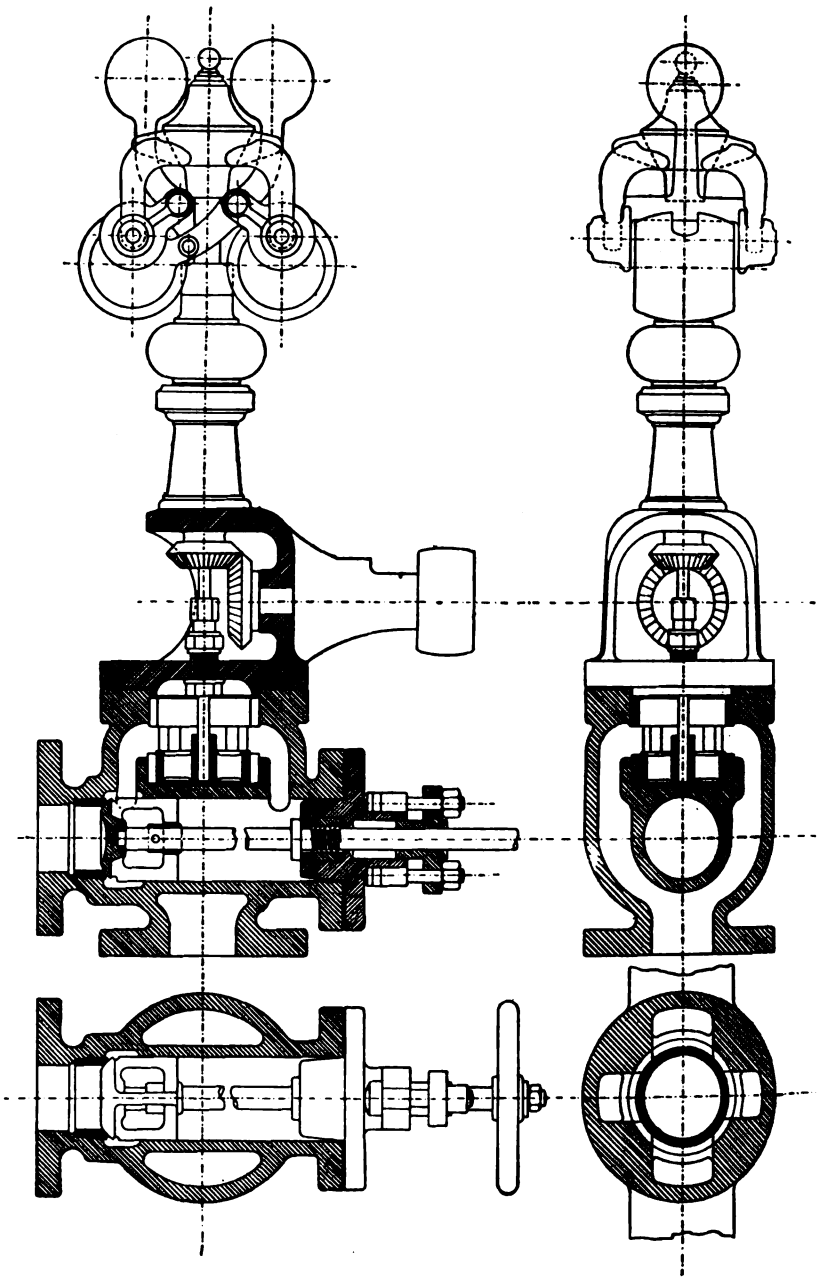

Fig. 13.

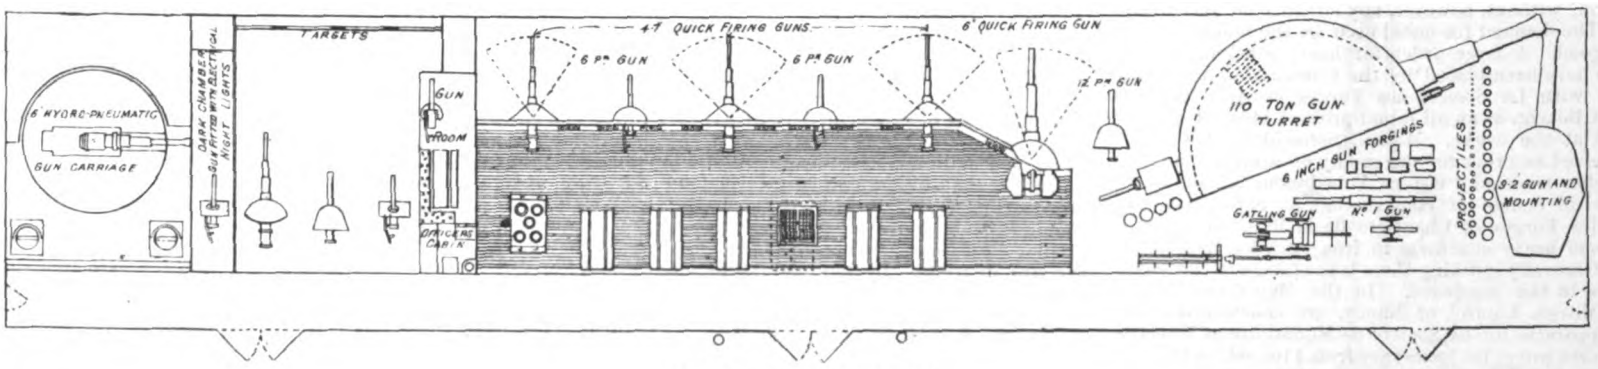
THE ROYAL NAVAL EXHIBITION.

The opinion we ventured to state in our last week's issue—viz., that on the opening day the Royal Naval Exhibition would be practically complete—has been fairly verified. In only one similar venture has there been at the formal opening greater signs of completeness, and it is evident that the promoters have at least worked so as to deserve success. This is apparent in more ways than one, and not the least important, to the visitor who desires to live and learn, is the care with which what may be styled petty exhibitors of the heterogenous class have been excluded. Further, in no case has the fact been lost sight of that it is a *Naval* Exhibition, taking the word in its broadest sense, as including the mercantile marine as well as the Navy proper.

In our present article we purpose taking a general survey of the Exhibition, indicating the character of the exhibits, and making passing allusions to some, in the various "galleries" into which the main buildings are divided.



On entering, turning slightly to the left, the Franklin Gallery is first to attract notice (see General Plan, *Industries*, Vol. X., page 218). A large number of the objects exhibited here consist of relics of the ill-fated Arctic Expedition in which Sir John Franklin and so many others lost their lives; thus, of more than passing interest are the models of the steamship "Fox" and of H.M.S. "Terror." The Blake, Nelson, and Benbow Galleries are next, and here the numerous specimens of art and other exhibits, while of general interest, call for no special mention. Passing on to the Howe Gallery, we see specimens of the various necessities required for victualling and clothing our sailors. Several private firms have also miscellaneous exhibits in this gallery, including Messrs. Shand, Mason, & Co., of London, who, amongst a variety of fire-extinguishing appliances, show their patent equilibrium steam fire engine as supplied for H.M. vessels "Hercules" and "Sultan." Messrs. Merryweather & Sons, of Greenwich, are also similarly represented, and to this firm has been entrusted the supervision of the fire brigade of the Exhibition. The Cook Gallery is next in order, and contains a vast variety of purely navigation exhibits, many of historic interest. In this category are the collection of chronometers, including the watch or timekeeper which gained for its inventor, Mr. John Harrison, in 1762, the reward of £20,000. The development of the mariner's compass can also be similarly traced, as also that of the quadrant, and the log. While many of these exhibits have been obtained from the Admiralty, those of private firms add to the value of the collection. The exhibitors of boat-lowering and disengaging apparatus are so numerous that it would be invidious to make special mention of individual exhibitors. Messrs. Watkins & Co., Blackwall, in their collection have several models of racing and cruising yachts, and a torpedo boat built for the Greek Government. Messrs. T. G. Tagg & Son exhibit a combined lifeboat and deck-seat, and Mr. R. J. Turk a centre-board dinghy fitted with self-reefing gear sails.

The Seppings Gallery is now reached, and in it there are many valuable objects of interest to marine engineers and shipbuilders. Here, very fittingly—for Sir Robert Seppings was an eminent naval architect and Surveyor of the Navy in the reign of George IV.—the great bulk of the exhibits illustrative of the construction of the hulls and machinery of seagoing vessels have been placed,

excepting special collections in separate buildings erected by several of the leading shipbuilders and steamship companies. Taking the latter into account, there is no doubt that at the Royal Naval Exhibition the science and art of naval architecture, and its sister science, marine engineering, is better represented than even at the Liverpool Exhibition of Navigation in the year 1886, although many historic vessels are not to the front which would have been had Lloyd's Register of British and Foreign Shipping been represented. Contributions from the Bureau Veritas, another society which did much to add to the completeness of the Liverpool Exhibition, would have also imparted an international character to what is, however, on the whole, a fair representation of the recent development of shipping. If in the mercantile department there are "missing links," it is at all events true that, so far as the Royal Navy and warlike vessels generally are concerned, there has never been a more complete representation at any exhibition.

Marine engineering exhibits are seen first in entering the Seppings by way of the Cook Gallery. Deferring for the present any attempt to describe these exhibits, we cannot but mention here the splendid display of Messrs. Maudslay, Son, & Field, London, of models of marine engines at work, as fitted by them in vessels of the Royal Navy, in a period ranging from the year 1823 to 1874, as also for their other exhibits, which include an air compressing machine for working torpedo gear to be fitted in H.M.S. "Royal Arthur." Messrs. John Penn & Sons, Greenwich, have also a first-class collection of miniature (working) marine engines, besides photographs of the triple-expansion engines now being fitted by the firm in H.M. ships "Sappho" and "Scylla." Probably we may be able to illustrate and fully describe these engines, which are designed to exert 9,000 i.h.p. Messrs. W. H. Allen & Co., Lambeth, exhibit an 18in. pumping engine, which they have specially constructed for H.M.S. "Royal Oak," which is capable of lifting 60,000lb. of water per minute from a depth of 25ft. Messrs. Fleming & Ferguson, Paisley, have a number of exhibits illustrative of their specialties, including their quadruple-expansion engines. Messrs. R. & W. Hawthorn, Leslie, & Co., Limited, Newcastle-on-Tyne, have contributed the working model of the triple-expansion engines for the Italian armourclad "Sardegna," which was specially constructed for the Newcastle-on-Tyne Exhibition. It is probably the most interesting exhibit of the kind, as it represents, on one-eighth of the full size, two sets of engines capable of developing 12,500 i.h.p., and which can be disconnected at will. The "Sardegna" is a twin-screw steamer, the engines represented by the model being merely those to drive the starboard propeller, and they are seen to advantage owing to the special electric lights fitted inside the case covering the exhibit. Other firms might take a lesson from this feature, for, while the general lighting arrangements leave little to be desired, in several instances, owing to shadows cast from screens, &c., objects of interest are undeservedly thrown in the shade.

Palmer's Shipbuilding and Iron Company here contribute their share to marine engineering exhibits, but, owing to their position, the miniature representation of the triple-expansion engines—on a scale of 3in. to the foot—of the s.s. "Flamborough" will, we are afraid, escape general notice. This is partially hidden from view by the collection of ship models exhibited by the company, of which we must defer our notice, as well as any further reference at the present to the remaining exhibits in the Seppings Gallery.

The most important of the separate buildings erected at the cost of the exhibitors is the Elswick Gallery of Sir W. G. Armstrong, Mitchell, & Co., Limited, which we illustrate above. A large portion of this building, which is 230ft. in length and 45ft. in breadth, is occupied with a representation of the 'tween-deck battery of a modern war vessel, with its ordnance in position, ready for action. Above this battery the space on the upper deck is utilised as a model room, in which a number of very completely full models of vessels built by the company are exhibited, besides a half-model, one-twelth the full size, of H.M.S. "Victoria." By having a mirror at the back, the visitor, standing on the raised gangway placed for the convenience of visitors, apparently sees a complete vessel. The whole work reflects great credit on the company's model maker, Mr. W. H. Mattison. At one end of the battery are completely fitted up officers' and midshipmen's cabins. Both these rooms are provided with Mason's recently improved pivoted sidelights. Beyond these rooms, a section is devoted to quick-firing guns, a moveable target being provided, at which the rapidity of firing combined with accuracy of aim can be tested. At the far end, a 6in. gun on a hydro-pneumatic carriage is seen. This type of gun-mounting is being very extensively adopted for coast defence, and in an early number we hope to describe the gun and carriage as actually exhibited, and to continue our description of the other exhibits from Elswick.

The St. Vincent Gallery adjoins Sir Wm. G. Armstrong, Mitchell, & Co.'s building, and is occupied by exhibits of ordnance. Here the contrasts between "culverings," "sakers," "falcons," "minions," "fauconets," "petarares," and a 67-ton breechloading gun, torpedoes, and other recently designed weapons of war are very manifest.

Leaving over for another time the account of the exhibits in the Camperdown Gallery, which are contributed by many leading iron and steel manufacturers, we would remind our readers that, located between the "Camperdown" and the water basin, are the kiosks of the Fairfield Shipbuilding and Engineering Company, Limited, Glasgow; Messrs. J. & G. Thomson & Co., Dalmuir, Glasgow; and the Royal Mail Steamship Company, Limited. In the latter, in addition to miniature representations of naval architecture, there is an elegantly fitted full-size model of a first-class cabin as fitted in the company's steamers. Between the Trafalgar Panorama and the "Victory" is the kiosk of the Thames Iron and Shipbuilding Company, Limited, in which considerable pains has been taken to obtain an effective as well as original arrangement of a variety of exhibits representative of the company's operations. Here also is a completely fitted-up stern cabin for a modern war vessel, while the main portion of the kiosk is taken up by a trophy in which are models of the company's dry docks and works, as well as of bridges, &c.

The Peninsular and Oriental Steam Navigation Company's kiosk, owing to not having any very distinctive outside display, is apt to be overlooked, but will well repay a visit. Even unfinished there is much of interest, including a model of the Suez Canal, large maps, well-finished models of several of the fleet, full-sized state rooms for first-class passengers, &c.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 5th May, 1891.

The Iron Market.—The Paris iron market still continues firm, without, however, any advance on last week's prices. The demand for metal used in the building trade is fairly good. A large order for heavy steel rails is reported to have been placed by the Chemin de Fer du Midi Company with La Société des Forges et Aciéries de la Marine at Boucan at an all round price of 140s. 6d. per ton delivered at the works. Messrs. Schneider, of Creusot, have received an order for the supply of armour plates for the Russian ironclad "Georgy Pobedononetz," of 10,000 tons, now in course of construction at Sebastopol. La Société des Forges et Chantiers de la Méditerranée have taken some heavy contracts in iron work for Mexico and Japan. Generally speaking there is no change in the aspect of affairs in the provinces. In the Meurthe-et-Moselle district Messrs. Cabirol, of Nancy, are constructing four Cooper apparatus for La Société de Montataire at Frouard. In the North prices for joists vary from 116s. 6d. to 120s. 6d. per ton according to the importance of the order; 3 millimetre No. 2 sheets are in fair demand at from 140s. 6d. to 145s., and steel sheets at 160s. per ton. The makers of galvanised iron sheeting and all kinds of domestic iron ware are very busy. A good deal of discontent is said to prevail at various points in the Ardennes, where one or two of the works have been temporarily closed, but in most cases the masters have acceded to the demands of the men, and it may be assumed that there will not be a general strike.

Shipbuilding.—The shipbuilding yards of La Seyne, Var, are hurrying on the completion of the Chilian ironclad "Capitan Prat." The "Presidente Pinto" is ready for sea. Of two cruisers for the Japanese Government built by the same firm, the "Itsukushima" has her armament on board, which, with the exception of one large piece of 34 centimetres furnished by Les Forges et Chantiers du Havre, has been supplied by Sir W. J. Armstrong.

Copper, Tin, and Lead.—A further fall in the price of copper has taken place. Best Chilian bars are now quoted at £56 5s., ordinary Chilian bars at £53 10s., and best selected at £58 5s. per ton. A contract for 800 kgr. of sheet brass for the preparatory workshops at Bourges Arsenal has been awarded at the rate of £64 4s. 6d. per ton. Tin and lead have also decreased in value. The former metal is quoted as follows:—Banca, £96 12s. 6d.; Billiton, £94 12s. 6d.; and Cornwall, £98 per ton.

The First of May in France.—The proposed working men's demonstration proved a fiasco at Paris, where nearly all the shops had their full complement of men, leaving the public squares to a few so-called Socialists and Anarchists. In some of the provincial towns, such as Chaleville, Tourcoing, and Roubaix, the men struck work generally, but apparently in an unorganised manner, and the whole affair seems to have been of a revolutionary political nature rather than a serious endeavour to arrive at a legally curtailed working day.

BERLIN, 4th May, 1891.

The Coal Industry.—The tenders sent in a few days ago for the supply of coal to the railways in the Berlin district gives some indication of the prices of coal in comparison with the prices in the English coal market. For a quantity of 120,000 tons of coal and patent fuel, the tenders included 120,000 tons of coal from the Ruhr district, 197,000 tons of Silesian coal, 30,000 tons of patent fuel, and 105,000 tons of West Hartley pit coal. Mr. W. Peschka, of Nüremberg, tendered for the whole quantity at £6 15s. per double waggon at the pit. Upper Silesian coal was offered by dealers at 8s. to 8s. 4d. per ton at the pit. The demand for English coal was supplied at 16s. 9d. to 19s. 2d. per ton delivered at Stettin, Stralsund, or Swinemünde, to the amount of 181,300 tons of rough coal. Twice the amount of coal required was tendered for from the Ruhr district at £5 9s. per waggon at the pit; 562,500 tons were offered from Silesia at from 6s. 5d. to 11s. per ton at the pit. The United "Gluckhilf" mine offered 120,000 tons at 11s. per ton; the Pleschen mines at Waldenburg offered to supply 37,500 tons at 10s. 2d. per ton; Messrs. C. Kulmitz, 55,000 tons at 10s. 2d.; and the Silesian coal mines at Gottesberg, 18,000 tons at 10s. 290,000 tons of English coal were offered at the prices already mentioned. An offer from the Ruhr district for the whole quantity was made at £8 18s. per double waggon at the pit. There were also offers to the amount of 35,000 tons at 16s. 6d. to 17s.; 20,000 tons of Silesian coke were offered by the "Glückhilf" mine at Hermsdorf at 16s. delivered at the pit. English coke was quoted at £1 5s. 6d. to £1 9s. delivered at Stettin, Swinemünde, or Stralsund. The 5,200 tons of forge coal required was tendered for to eight times the quantity at 8s. to 10s. 9d. per ton for Silesian and 15s. 5d. to 18s. 2d. for English coal. With reference to the supply of coal to German shipowners, an important amount has been secured by the Westphalian mines, whilst the North German Lloyd Company at Bremen holds back. This company some time ago bought 70,000 tons of English coal at 19s. delivered at Norderham. It is reported by some persons that coal of the same quality might have been obtained in Westphalia at 16s. 6d. to 17s., but it is somewhat doubtful whether the quality would have been so good. The Imperial Navy has obtained a supply of best Westphalian lump coal for the current year at 13s. per ton at the pit, and also its supply for the year 1892-93 at 13s. 6d. per ton. It has also obtained a supply of coal for use in the naval workshops at 10s. 6d. at the pit.

VIENNA, 4th May, 1891.

The Iron Market.—There is no important change in the iron market, which continues quiet owing to the reserved attitude of buyers. The Northern Railway Company has placed an important order for axles and wheels. Manufacturers felt some anxiety with regard to the demonstrations on the 1st of May, and in the smaller towns demanded military assistance. At Budapest the State Railways, the shipbuilding establishment, Mr. Lang, and Messrs. Ganz & Co. all resolved to dismiss every man who should leave his work on that day without urgent reason. Similar measures have been resolved upon in other coal and iron districts. In these industries labourers are especially discontented with their lot.—The Egidy Iron Works have resolved to pay a dividend of 4 per cent., as compared with 3½ per cent. in the previous year.

The Coal Market.—The coal market is very active, notwithstanding the advanced season and the small demand for household sorts. There is a large export from North-West Bohemia, and large quantities have been despatched from Aussig, Brux, and Dux into the strike districts. The Lloyd Company may possibly become the property of the Government, and foreign contractors would then be hard pressed by native firms. The negotiations of the Lloyd Company with the State will therefore be interesting to English coal contractors.

Commercial Treaty between Austria and Germany.—This treaty, which has been discussed during the past five months, was signed here yesterday afternoon. The treaty will last for twelve years, and the most-favoured nation clause will be in operation with reference to trade between the two countries. The treaty will also affect other countries in their tariff arrangements with Germany and Austria, as the latter countries have agreed to carry on their negotiations in common. The new treaty is the first which has been concluded between Germany and Austria since the year 1878. In consequence of the new treaty the Austrian customs duty on iron will be decreased from 1s. 6½d. to 1s. 2d.

Electrical Engineering.—It is rumoured that the town of Frankfort has made private arrangements with Messrs. Ganz & Co. for a system of electric lighting. A declaration as to the truth of this report is looked for from this firm, in order that the uncertainty of their numerous competitors may be set at rest. The town of Arad, in Hungary, which has 43,000 inhabitants, has asked for tenders for the electric lighting of the public streets, squares, and gardens. The principal competitors are Messrs. Ganz & Co., of Budapest, and Messrs. B. Egger & Co., of Vienna.

The Monchsberg Electrical Railway.—The electrical railway which ascends the Monchsberg, near Salzburg, had carried 66,712 passengers and more than 1,000 tons of goods up to the end of last year. The net profits amounted to £40,871. It has been decided to enlarge the central station at Salzburg.

Electric Light in Bulgaria.—The Austrian General-Consulate at Sofia, Bulgaria, has been notified by the Municipality to state that tenders for an electric light installation will be received. The time for receiving such proposals expires on the 13th of July, 1891.

Implement Competition.—A competition for threshing machines will be held in Bucharest, at the Ministry of Agriculture, from August 10th to August 15th, and another for sowing machines from September 10th to September 15th. The competition will be held before a special jury, and the Minister of Agriculture will award prizes for the best machines.

BRUSSELS, 5th May, 1891.

The Iron and Steel Market.—There is no improvement in the iron and steel market. The price of the finished product does not rise in proportion to the increased cost of raw material. Business will continue sluggish so long as the price of coal is maintained. The outlook is not promising, as industrial works are not showing the activity which is customary at this season of the year. Joists are quoted at £5 3s., and sheet iron at £6 6s. The import and export of iron and steel have considerably decreased. There is a decrease in the import of steel of 22,000 tons, as compared with the import during the first three months of this year, a decrease of 1,000 tons in iron sheets, of 1,000 tons in rolled iron, of 7,000 tons in pig iron, and of 4,000 tons in railway rolling stock. Contracts for the supply of third-class carriages for the Belgian State Railways have been awarded again. The International Company has obtained contracts to the amount of £5,120; the Malines Company, £5,080; Messrs. Nicaise & Delceeve, £6,000; and M. Verhaegen, £5,090. Goods waggons have been tendered for as follows:—The Metallurgical Company, to the amount of £3,300; the Deyle-Baculan Company, £3,304; the Franco-Belgian Company, £3,312. The Malines Company has obtained a contract for 120 waggons for the Gothard Railway, and the Deyle Company is well employed in the construction of bridges for Asia Minor and of waggons for railways in Holland. This company has just started a system of drying by means of a "thermosyphon," which has been favourably considered by specialists. For the Belgian State Railways the contract for waggon doors has been given to La Société des Forges of Bousval.

The Coal Market.—Prices are well maintained in the coal market. The coalowners allege the existence of strikes as a sufficient reason for making no concessions. The smallness of the stocks at the coal mines forces customers to renew their supplies, notwithstanding the high prices. Prices remain steady with small variations. Small sorts of coke are quoted at 9s. 4d., best coke at 14s., close burning sorts at 5s. 10d. to 6s. 8d. Coal for blast furnaces varies from 9s. 2d. to 10s., and fuel for metal furnaces is quoted at 11s. 3d. Representations are being made with a view to the reduction of the charges for transport. The imports and exports of fuel during the first three months of the year are shown in the following tables:—

Imports.

	Coal.	Coke.
Germany	144,816 tons	21,500 tons
England	110,936 „	13,048 „
France	44,171 „	240 „
Netherlands	6,742 „	1,571 „
Other countries	4,499 „	—

There is thus a diminution in the import of coal, but the import of coke has been trebled.

Exports.

	Coal.	Coke.
Germany	33,269 tons	12,456 tons
England	7,666 „	—
France	918,985 „	187,186 „
Luxemburg	54,588 „	35,350 „
Netherlands	39,516 „	—
Other countries	33,202 „	8,938 „

The export of coal shows a small increase, whilst the export of coke has been diminished by about 30 per cent.

Microscopic Exhibition at Antwerp.—An international exhibition of microscopical instruments will be held in Antwerp in the months of August and September next, in commemoration of the invention of the microscope 300 years ago. Applications for space should be made by intending exhibitors to Dr. Henri Van Heurck, Jardin Botanique, Antwerp. The exhibition promises to be of an interesting character.

DÜSSELDORF, 5th May, 1891.

The Iron Market.—The general condition of the iron market is much affected by the strike amongst the miners, which, however, is now nearly at an end. The coal market is on the whole firm, the demand for home manufacture is small, and there is no improvement in pig iron. The bar iron market has improved, and there is also a greater demand for coarse and fine sheets. It is intended to erect a common place of sale for both these articles. It has also been proposed by the ironmasters in the Siegen district to institute a union for the sale of the iron. Those works which are employed in making railway material are provided with orders for the next few months. Machine works and iron foundries are fairly well employed. The following statistics of the stores at the blast furnaces are given:—

	March 31, 1891.	Feb. 28, 1891.
Puddled and spiegel iron	38,356 tons	39,274 tons
Ordinary puddled iron	4,605 „	5,901 „
Bessemer iron	11,888 „	9,467 „
Thomas iron	23,200 „	27,840 „

Exhibition.—The Electrical Exhibition at Frankfort-on-the-Maine will be opened on the 15th inst.

The Steamship "Bismarck."—The twin-screw steamship "Bismarck," built by the Vulcan Ship Wharfs at Stettin for the Transatlantic service, and which is now being completed at Swinemünde, is the largest vessel of the German navy. When fully loaded its displacement is 12,900 tons. The steamer has two triple-expansion engines of 7,000 h.p. each. The speed is estimated to be about 19 miles per hour.

AMSTERDAM, 4th May, 1891.

Labour Questions.—The 1st of May demonstration of certain portions of working men in Holland have given some trouble to the authorities, who had made certain preparations to meet it. The day passed off in a very quiet manner. In Amsterdam, The Hague, and in other towns, fairly attended mass meetings took place to insist upon the "right" of the labourer to work eight hours a day, and no more. Some violent speeches were delivered, but no disturbance occurred.

The Blitong Tin Company.—The extraordinary meeting of shareholders of the Blitong Tin Company, held at The Hague, has sanctioned the draft of a contract between the company and the Dutch Government for a settlement of the questions in dispute, and for an extension of the concession till the year 1927. The chief points of the new agreement have been given in a previous letter (see *Industries*, Vol. X., page 367). Like the Government, the shareholders have declared in a separate resolution that the agreement contained the utmost limit of their concessions.

THE AMSTERDAM QUININE FACTORY COMPANY.—In 1890 this company manufactured 21,894lb. of quinine. The net profit, however, was too small to allow a dividend to be declared.

NEW INDUSTRIAL COMPANY.—The Dutch Government has sanctioned the articles of association of the American Petroleum Company, established at Rotterdam, with a capital of £416,666, for the purpose of combining the businesses of the Standard Oil Company at New York with those of its agents at Antwerp and Rotterdam. The latter place is intended to become the chief petroleum centre of the American trade.

DUTCH SOUTH AFRICAN RAILWAY COMPANY.—Messrs. Labouchere, Oyens, & Co., of Amsterdam, have opened the subscription for shares of the value of £500,000 in the Dutch South African Railway Company, forming the third and fourth series of the entire capital of the company, which amounts to £916,666. All these shares bear the unconditional guarantee of the Transvaal Government for 6 per cent. interest. The works on the line from the Portuguese frontier to Pretoria are now rapidly approaching their completion. The price of some of the shares is 115 per cent.

STOCKHOLM, 2ND MAY, 1891.

THE SWEDISH IRON INDUSTRY.—At the quarterly meeting of the Society of Swedish Ironmasters, held at Stockholm on the 28th ult., it was stated that the exports during the first quarter of the present year were as follow:—

	1890.	1891.
Pig and ballast iron ...	5,031 tons	3,416 tons
Ingots	1,666 ,,	568 ,,
Blooms	1,978 ,,	1,661 ,,
Other rolled or hammered bars	26,417 ,,	25,190 ,,
Ends of bars.....	199 ,,	259 ,,
Wire iron	313 ,,	53 ,,
Plate iron	1,386 ,,	853 ,,
Nails	474 ,,	548 ,,
	37,464 tons	32,548 tons

showing a decline, as compared with last year, of nearly 5,000 tons for the first three months of the present year. In the banks there were warrants for the following quantities, on April 1st:—Pig iron, 25,932 tons; bar iron, 9,434 tons; other iron, 16,585 tons; total, 51,951 tons; which is about 7,000 tons more than on April 1st last year. There are in Sweden 191 blast furnaces, 527 furnaces, 33 Bessemer converters, and 32 Martin furnaces, of which the following number were in use during the first quarter of the years 1890 and 1891:—

	1890.	1891.
Blast furnaces	131	138
Furnaces	392	374
Bessemer converters ...	24	23
Martin furnaces	23	28

with a respective production of—

	1890. Tons.	1891. Tons.	Increase. Tons.	Decrease. Tons.
Pig iron	118,839	127,983	9,144	—
Blooms	55,639	54,258	—	1,381
Bessemer ingots	21,423	23,318	1,895	—
Martin ingots ...	14,597	18,163	3,566	—

With an increase of about 9,000 tons in the production of pig iron there is an increase of about 5,500 tons in the manufacture of steel. During the first quarter of the present year the foreign iron markets have on the whole been dull, and the Swedish ironmasters have also been obliged to lower their quotations. For pig iron there is no large demand, but hammered Lancashire has been in better request, and most of the works concerned in this manufacture are well employed. The following quotations, per ton of 1,016 kgr., without discount, were agreed upon:—

	F.o.b Gothenburg. £ s. d.	F.o.b. Stockholm. £ s. d.
Ordinary hammered iron	8 2 6	8 0 0
,, rolled iron.....	7 12 6	7 10 0
Rolled finer iron	8 2 6	8 0 0

THE ZONE TARIFF.—The zone tariff, which has now been worked with satisfactory results for many months by some of the private railway companies, is gaining ground in Sweden. The Second Chamber has made representations to the Government that the question should be investigated in order to effect a reduction in the passenger fares, so as to facilitate the intercourse between the different parts of the country.

CHRISTIANIA, 2ND MAY, 1891.

CONTEMPLATED DRY DOCK.—The construction of a dry dock at Oorevaagen is being favourably considered at Christiansand. The expenditure is calculated at about £16,666.

DR. NANSEN'S ARCTIC EXPEDITION.—The question of where the vessel for Dr. Nansen's Arctic expedition should be built has now been decided, Mr. Collin Archer, of Lourvik, having secured the contract.

THE LOFOTEN FISHING.—This year's fishing at Lofoten amounts to about 21 million fish. The yield of medicinal oil is the largest on record, that of roe somewhat small. The following table gives the respective quantities for the last five years in hectolitres:—

	Roe.	Medicinal Oil.	Liver.
1891 ...	19,600	18,200	22,700
1890 ...	24,000	16,700	58,500
1889 ...	19,800	12,900	23,500
1888 ...	39,000	16,100	38,000
1887 ...	29,850	9,500	38,200

The prices for roe varied much, but were, on the whole, low.

MADRID, 4TH MAY, 1891.

THE MANHÉS PROCESS FOR COPPER.—This process for obtaining copper has been successfully started at the mines of Jerez-Lanteira in the province of Granada. The remaining sulphur and other minerals are eliminated from the crude matte at a single operation. Assays made at Jerez-Lanteira show from 99·5 to 99·75 of pure copper. The process was soon in regular working order, and after a few days the chief engineer was able to leave its management in the hands of his subordinates. The Manhés process, which is employed in the treatment of sulphuret of copper is especially applicable to such cases as that of Jerez-Lanteira, where fuel is very costly, the air being blown into the Manhés converter by hydraulic power at a distance from the works. No fuel is required except for the first smelting of the ores to make the matte. The Fives-Lille Company has carried out the general installation, which is to be applied also to the working of rock drills.

THE BARCELONA AND MARSEILLES TELEGRAPH CABLE.—This cable, which was laid down seventeen years ago has worked without interruption up to the 10th ult. The damage then done was soon mended by the Eastern Telegraph Company, and the cable was again in working order on the 13th ult.

SALE OF THE PEDROSO IRON MINES.—For some weeks past it has been rumoured that an English company was about to purchase the extensive iron mines and old-fashioned iron works belonging to the Pedroso Company. This company was obliged to suspend payment about three years ago, as it was unable to pay interest on its debentures. The price paid for the property is said to be £260,000, besides a commission of £40,000. This is considered a very high price. The company possesses land worth about £30,000, iron works valued at about £25,000, and the mines must therefore be estimated to be worth £200,000. Perhaps the buyers are better acquainted than the natives with the quantity of ore contained in the mines.

ROME, 4TH MAY, 1891.

ITALIAN METALLURGICAL AND CHEMICAL WORKS.—The following table shows the production of metallurgical and chemical works in Italy in the year 1889:—

Products.	Number of Works.	Production. Quantity. Tons.	Value in Units. Lire.	Total Value. Lire.	Number of Men Employed.
Pig iron	11	13,473	157·58	2,123,096	227
Iron and Steel	323	181,623 157,899	277·33 223·78	50,343,398 35,185,837	14,518
Gold.....	3	212	2,640·15	569,848	89
Lead	1	18	340·00	6,176,100	700
Silver		33	150·00	5,025,750	
Copper and its alloys..	9	6,904	1,773·75	12,246,000	1,638
Antimony ...	1	1,969	—	280,066	44
Mercury	3	378	5·90	2,274,450	43
Salts.....	77	430,639	—	2,919,092	5,037
Aluminite & sulphate of alumina ...	8	4,047	—	456,840	125
Refined sulphur	17	53,816	93·00	4,958,586	269
Patent fuel ...	22	520,450	—	16,515,900	618
Total.....	475	1,369,961		139,074,963	23,308

SHIPBUILDING.—Two fine steel cruisers, the "Etruria" and the "Umbria," have been launched from the yard of Messrs. Orlando Brothers, at Leghorn. They are provided with armoured bridges, and are each of the capacity of about 2,300 tons. Their length is 80 metres, beam 12 metres, and depth 8·6 metres. The engines, which have been constructed at the works of Messrs. Orlando, are on the triple-expansion system, and develop 6,500 h.p. A speed of 19 knots per hour will be attained. The designs of these vessels have been made by the Italian naval authorities, and the engines have been designed by Messrs. Orlando. The engines are intended to develop the maximum of power with the least possible weight, and are said to combine all the latest improvements in naval engineering.

NEW YORK, 25TH APRIL, 1891.

PNEUMATIC GUN CARRIAGE.—A pneumatic disappearing gun carriage for a 10in. breechloading gun, which was built at Boston, under a contract with the Board of Ordnance of the Army, has arrived at the Government Proving Grounds, Sandy Hook, and will be in place, ready for a series of practical tests, about May 10th. The 10in. steel breechloading gun, built by the War Department, which was successfully tested at Sandy Hook, and which broke the French carriage, made by the Creusot Works, upon which it was mounted, a year ago, is to be mounted on the disappearing carriage in a pit below the surface of the ground.

LARGE CASTING.—One of the largest castings ever made in Worcester, Mass., was poured at the Star Foundry recently. It was a fly wheel, weighing over 20 tons, and was 20ft. in diameter, with a 42in. face. It will be finished in Fitchburg, there being no lathe large enough in Worcester.

ELECTRICITY IN A GLASS FACTORY.—The Pittsburg Plate Glass Company, of Ford City, Pa., is adopting the use of electric motors in its large plant in that city. The company has a glass polishing table which is said to be quite novel, and economical in comparison with similar machines. These tables are over 30ft. in diameter, and are revolved by gearing which has heretofore been operated by steam. The Thomson-Houston Motor Company has now installed a 100 h.p. motor to operate these polishing tables.

LATHES FOR BORING GUNS.—The United States Government has given an order for eight lathes to be used for trimming and boring guns. They will cost over £80,000, and an idea of their size may be formed from the fact that one of them will weigh 250 tons.

MEASURING INSTRUMENTS.—Messrs. Darling, Brown, & Sharpe, of Providence, R.I., are issuing an artistic reproduction of the diploma they received at the Paris Exhibition of 1889 in respect of their exhibit of accurate measuring instruments.

PHILADELPHIA, 24TH APRIL, 1891.

THE STRIKE IN THE COKE REGIONS.—The trouble at Connelsville and the surrounding coke regions still continues. During the past week considerable rioting has been going on. The labour leaders have been informed by the Frick Company that 500 experienced miners from the Punxsutawney coalfields have been engaged to work in the various mines of the company. The Frick Company has also engaged the services of a number of Pinkerton detectives, 500 of whom are already on the grounds, and will guard the mines at which the men are at work. A regular battle occurred between the sheriffs and some Hungarians while the former were making evictions. The arrival of a company of the National Guards put a stop to the fight, but not until after there had been some bloodshed. The owners of bituminous coal mines in Indiana have decided to resist the eight-hour day movement announced for May 1st, and refuse to pay for mining before the coal is screened. They have also decided that the wage schedule for the year beginning May 1st shall be on the basis prior to this year—that is, 2½d. less for the summer months than for the winter, and that the rate shall be 7½d. per ton less than for block coal.

NAVAL.—Two nickel-steel plates, which are to be used as armour, have been received at the Navy Yard in Washington, whence they will be taken to the proving ground at Indian Head, Maryland, in order to be practically tested. These are the first American plates made, and much interest is manifested in the test. The plates are 8ft. long, 6ft. wide, and 3in. thick. The official report of the trial trip of the gunboat "Bennington" has been received at the Navy Department. It showed that the main engines developed 3,323 h.p., which, with the auxiliaries, made the total 3,436 h.p. With the steam pressure at 166lb., the starboard engines made 150·82 revolutions, and the port engines 151. Under authority conferred by Congress, the Secretary of the Navy is making arrangements to reopen the League Island and Boston Navy Yards for construction and repair works. Tenders for furnishing the yards with tools have been opened, but the contract has not yet been awarded.

RESUMPTION OF WORK.—A general resumption of work has taken place at the Edgar Thompson Steel Works of Messrs. Carnegie, Phipps, & Co. The works have been closed for about two weeks, and the resumption will give employment to about 2,000 men, but will, it is stated, last only a short time. The Brooke Iron Company's mines at French Creek, about thirty miles from this city, which have been idle for two years, are about to resume work. The Temple Iron Company, of Temple, which has been prospecting for ore on an adjoining track, struck a rich deposit at a depth of 150ft. Along the East Penn Road, several other mines which have been idle during the winter have resumed work.

THE PROPOSED INTERNATIONAL RAILWAY.—The Pacific Mail steamship "Newport," which sailed for Central America, carried a party of engineers to study the feasibility of the proposed international railway, designed to connect North, Central, and South America. The party comprises Mr. W. F. Shunk, chief director of the enterprise, Mr. J. Inurie Miller and assistants, Mr. Joseph Parker and Mr. J. D. Forster, of Harrisburg, and five members of the United States Navy. The expedition will last two years, and each member has contracted to remain one year. Its object is not to make surveys, but rather to make observations of and to study the system of railroads now in use in the Republic, the local lines, and their uses and possibilities. Maps and plans will be prepared in such a way as to show the possibility of a railway system extending the entire length of South America.

NEW INDUSTRY AT AMBLER.—The town of Ambler, in this State, will soon have another large manufacturing industry. It will be known as the Halsey Manufacturing Company, the leading members of the firm being Philadelphians. The product will consist of steel drills and kindred implements. The capital is to be £10,000, and about 100 mechanics will be employed at first.

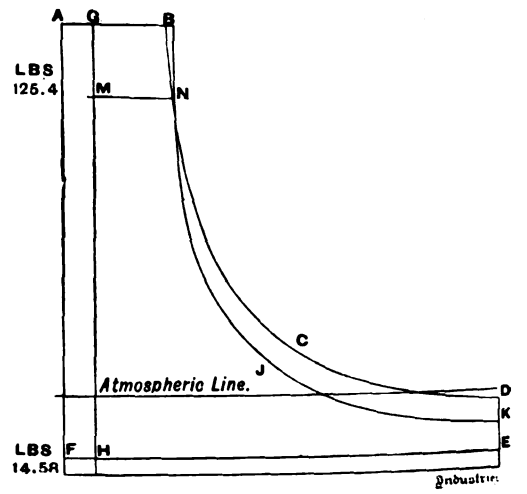
THE INSTITUTION OF MECHANICAL ENGINEERS.

The ordinary general meeting of this Institution was held on the 30th ult. and the 1st inst., at the Institution of Civil Engineers, Great George Street, Westminster, Mr. Joseph Tomlinson, President, being in the chair. After the transaction of the usual formal business, the Secretary read the report of the



Research Committee on Marine Engine Trials: Report upon Trials of the S.S. "Iona."

The result of these trials will be found in some respects more complete than any of those previously made by the committee. The steamer tested, built in 1889, is 275·1ft. long, 37·3ft. beam, and 19ft. depth, with a gross registered tonnage of 2,094 tons. Her mean draught during the trial was 20ft. 7½in., corresponding to a displacement of 4,430 tons. The trial lasted sixteen hours, ending at 10.30 a.m. on July 14th, 1890, the weather being fine throughout. The speed of the engines was not altered nor was the valve gear touched during the trial, and in addition to all the observations taken on former occasions, indicator diagrams were taken at intervals from the circulating and air pumps, from the first and second receivers, and from both ends of the condenser. The temperatures of the circulating and discharge water were noted, and the jacket-water, steam pipe drain-water, and supplementary feed-water were each measured. The engines have cylinders of 21·88in., 34·02in., and 56·95in., each with 39in. stroke. The high-pressure cylinder only is jacketed, and this during the trial was drained into a measuring tank. The clearances of the cylinders are given as 12·41, 10·11, and 7·64 per cent. of the volumes swept through by their respective pistons. The high and low pressure cylinders have ordinary double-ported slide valves, the intermediate a Trick slide valve, the gear being the ordinary link motion. The pumps are all driven from cross-head of low-pressure cylinder. The surface condenser contains 1,360 square feet of tube service. The four-bladed cast-iron propeller is 14ft. 6in. diameter, with a mean pitch of 14ft. 6in. Steam, at a mean pressure of 165lb., was supplied by two single-ended double-furnaced steel boilers, of 13ft. 3in. mean diameter, and 10ft. long, worked under forced draught. Each grate was 3ft. 6in. broad, and had fire-bars 3ft. long, thus giving a total grate of 42 square feet. The total heating surface is 3,160 square feet, 2,590 square feet being tube surface. The Tyne coal used was weighed, and the consumption plotted out in one of the diagrams accompanying the paper, the first portion of which is given on page 448. From the thirty-two sets of diagrams taken the following mean effective pressures were found to exist in the high, intermediate, and low pressure cylinders respectively — viz., 46·65lb., 20·44lb., and 7·16lb.—and these correspond with the following horse-powers:—205·6, 221·2, and 218·6, or a total of 645·4 mean indicated horse-power, with an average throughout the trial of 61·1 revolutions per minute. The mean boiler pressure was 165lb. above the atmosphere, and the mean barometric pressure 14·58lb. (29·67in. of mercury), the mean vacuum being equal to 28·25in. of mercury. The actual boiler efficiency was 69·2 per cent. of the thermal value of the fuel. The absolute engine efficiency, or ratio of the heat turned into work to the heat given to the feed-water, was 17·1 per cent., the combined efficiency being equivalent to 11·8 per cent. The coal burnt was at the rate of 1·46lb. per indicated horse-power per hour. A mean speed of 8·6 knots was maintained throughout the trial.

Professor Kennedy, who opened the discussion, hoped that the interest of the paper would more than than compensate those who attended for its apparent dryness, and suggested that the paper was a difficult one to follow. He regretted that the failure of the apparatus designed for measuring the amount of priming had prevented their investigations of this part of the trial being carried to a successful termination. Referring to certain of the diagrams accompanying the paper, he explained that these were shown shaded in error. In concluding his introductory remarks, he stated that in these trials the Committee had endeavoured to give in this paper information asked for in connection with the previous papers. He congratulated Mr. Brown, the chief engineer of the ship, on the data obtained at the subsequent trial independently carried out by him, and he was glad that the results obtained by that gentleman so closely approximated to those of the Committee.

The President then called upon Mr. J. R. Fothergill, the superintending engineer to the owners, who, after asking to be allowed to speak later on, was ultimately persuaded to give his experiences of the ship. Mr. Fothergill stated that he could not very well criticise the paper, as his position somewhat militated against his doing so. He explained that a deflector plate which should have been shown in Fig. 1 was omitted. The object of this plate was to deflect the gases and give as complete combustion as possible in the combustion chamber. The lowness of pressure in the ash-pit he attributed to cleanness of fires and no formation of clinker; hence the air passed freely through, and the pressure kept low. Notwithstanding this, there was an exceptional quantity of air, and he considered the good combustion obtained was due to this. He thought that the tables of results obtained bore out the fact that these trials were not undertaken to furnish any fancy figures, but to obtain data as to work done under ordinary average working conditions

Mr. Mudd (the manager of the firm who built the engines), after complimenting the chief engineer of the "Iona" for his energetic labours, and also Mr. J. R. Fothergill for his admirable superintendence, stated that he was thoroughly satisfied with the trials: (1) Because the coal consumption agreed closely with the best records they had been able to obtain from time to time from sea-going engineers; (2) because the water consumption was somewhat less than he anticipated. The engines were of the triple-expansion type, and the boilers of ordinary construction, fitted with Mr. Fothergill's system of forced draught. One of the principal features of these engines was the arrangement of the cylinders. The high-pressure cylinder was placed in the middle, and had three metals or walls around it. Counting from the inside the first metal is the working barrel. Between the first and the second metal a space forms a steam jacket at full boiler pressure. This is the only jacket about the engines, and is the one referred to throughout the report. The space between the second and the outer wall is partly the receiver between the first and second cylinders, but mainly it is the receiver between the second and third cylinders. The jacket, therefore, gives off heat inwards to the first cylinder, and outwards to the receivers. Doubtless this double action of the jacket accounts for the large condensation therein shown in the report—namely, 4·3 per cent. of the whole feed. When the engines were at work in the ordinary way without the measuring tanks, two objects were accomplished at once by very simple means—viz., the securing of a well-drained jacket, and a highly heated feed, by simply carrying the drain pipe from the jacket into the feed suction pipe, which takes the water from the hot-well to the feed pumps. In this way the feed can be heated to 160° or 180° Fahr. without the pumps refusing duty. Mr. Mudd said that the position of the jacket, especially in relation to the receivers; the efficient drainage of the jacket; and the use of a high feed temperature in conjunction with a low condenser temperature, all tended to economy. On the official trial, at least one of these things was necessarily interfered with—viz., the feed temperature—because the act of measuring in tanks, that took a quarter of an hour to fill, brought down the temperature to an average of 106° Fahr., as seen by the report. There might yet be some persons who would doubt whether this would have any effect on the consumption, and therefore it is very fortunate that the engineer was able to make a trial of the consumption in the same manner as that adopted by Professor Kennedy, omitting the water measurements, which trial showed in a most satisfactory and convincing manner that, had the feed temperature been 160° instead of 106°, the consumption would have been in the region of 1·38lb. per horse-power per hour instead of 1·46lb. A correction for this would increase the boiler efficiency from 69·2 per cent. to 73·4 per cent., increase the total efficiency from 11·8 per cent. to 12·55 per cent., and leave the engine efficiency where it was—viz., at 17·1 per cent. Referring to the question of the supplementary feed supply, and which amounted to as much as 6·1 per cent. of the total feed, it was noticed that the feed pump glands were not quite in order; but the leakage did not appear anything alarming, although the fact of turning on suddenly a big tank full of water, causing the pumps to run almost full-pump, had a tendency to make the leakage worse. There was also some leakage at the large 4in. cock at the bottom of the measuring tanks. Although no one thought these leakages serious, it is astonishing what a large quantity of water can pass in sixteen hours in what appears to be a very small leak; and here again a careful test made by the engineer on this very ship, but in this case made *previously* to the official trial, and covering as long a period as nine days, is accessible, and shows what one would naturally expect—viz., that 6·1 per cent. was very greatly in excess of the ordinary supplementary supply necessary. As good fortune again would have it, the horse-power during that trial was about the same, and certainly not *less* than on the official trial, so that he was safe in taking the same total feed for a basis. Assuming that at the time of this trial of the engineer there was absolutely no leakage at feed pumps, it would still appear that as much as 6,622lb. of water must have been measured on the official trial without ever reaching the boilers. This reduces the water consumption from 13·35lb. per horse per hour to about 12·69lb. It also reduces the efficiency of the boiler again to 69·8 per cent., increases the efficiency of the engine from 17·1 per cent. to 18 per cent., and leaves the total efficiency where it was by the last correction—viz., 12·55 per cent. Attention has of late years been very forcibly and very properly called to the condensation taking place in cylinders; and in the report it is stated that at 125·4lb. above the atmosphere there was present, by the indicator diagrams, 63·4 per cent. of the feed as steam and 36·6 per cent. as water; at 19·4lb. pressure, 74·9 per cent. of steam and 25·1 per cent. of water; at 8·6lb. pressure, 59·1 per cent. of steam and 40·9 per cent. of water; these calculations being made on a total water consumption of 2·35lb. per revolution. Commenting on this, he wished to state—Firstly, the correction for water measured but not put into the boiler, and alluded to previously, alters the total water per revolution to 2·23lb., and the percentages of steam and water to the following, viz.—At 125·4lb., 66·8 per cent. of steam and 33·4 per cent. of water; at 19·4lb., 79 per cent. of steam and 21 per cent. of water; and at 8·6lb., 62·4 per cent. of steam and 37·6 per cent. of water. Secondly, that the condensation should be apportioned as much as possible wherever we have known quantities, and thus reduce the unknown sources of loss to a minimum. For instance, it was shown that 6·15lb. of water went through the jacket per minute; and that ·88lb. were collected at the steam pipe per minute, neither of these quantities ever going into the working cylinder at all. Making further reduction under these heads to try to arrive at the actual condensation *within* the cylinders, he got a total water consumption entering the cylinders of 2·115lb. per revolution, and the percentages of steam and water fall to the following:—At 125·4lb., 70·5 per cent. of steam and 29·5 per cent. of water; at 19·4lb., 83·2 per cent. of steam and 16·8 per cent. of water; and at 8·6lb., 65·7 per cent. of steam and 34·3 per cent. of water. Mr. Mudd had no reason to suspect, he said, that any less quantities of water than the latter were in existence in the cylinder at these various points, but he was anxious that it should not be all attributed to "initial condensation." He thought that Professor Kennedy or some other person might do a valuable work in attempting to further subdivide and apportion to known causes as much as possible of this water. For instance, looking for a moment at what goes on with regard to the cushioning steam—viz., that steam, which, while existing as steam in the cylinder, is not measured or taken into account at all, and rightly so, because the cushion steam is properly regarded theoretically as a fixed and constantly existing quantity that is simply expanded and compressed like stretching and relaxing an elastic band—we have to deal with the fact that we cannot take work out of steam by expanding it and put it back again by compressing it *without loss*: indeed, there must be a loss in the act of expanding, and a further loss in the act of compressing. Therefore a portion of the cushion steam has to be made up by fresh steam at every stroke

to balance the condensation due to these necessary losses in the expansion and compression of the "cushion." If the precise efficiency of the cushion steam could be determined, the water in the cylinder could be subdivided, apportioning to this inevitable source of loss its proper share. On the same grounds he had hoped much from the ingenious attempt that was made on this trial to determine the priming water; and if the apparatus had not given out, we should doubtless have been in a position to charge to that cause also *its* proper share of the water found in the cylinder. Mr. Mudd here made a sketch of a diagram, which is given above, showing the ratio of the realised work to the theoretical work, and taken in two or three different ways. All the horizontal measurements of the engine diagrams are set off from a vertical line G H, thus obliterating the effect on the appearance of the diagrams of the compression. This causes them to overlap, and the area

Digitized by Google

of the overlapping parts is equivalent to the shaded areas. The distance between the two vertical lines represents the volume of the compression steam at the time of admission to horse-power cylinder, and which, in this instance, is equal to the clearance volume. The upper and lower limits of the diagram are the upper and lower pressures registered in the cylinders by the indicator: and lower down there is a zero line shown. The volume M N represents the 1·49lb. of steam stated in the report to be present in the cylinder at 125·4lb. above the atmosphere. The point N, therefore, has been taken as the origin of the two curves, and the curves are both what are known as "ten-ninth" curves—that is, the pressure varies as the reciprocal of the ninth root of the tenth power of the volume. The outer curve B C D represents the expansion of the whole steam in the cylinder, including the cushion steam, and the realised work represents 75 per cent. of the whole work-area A B C D E F. Leaving off the area A G H F, the work realised is 83·6 per cent. of the remainder G B C D E H. This latter percentage is of little value however, because, if the cushion steam be left out of the comparison at all, it should be left out up to a curve dropped from G, with the quantity of steam A G. The more interesting way to look at it, he said, was the following:—M N is the working steam found in the cylinder at 125·4lb. pressure. The lower curve N J K represents the expansion of a quantity of steam M N, as though it were expanded in one cylinder to a volume H E, equal to the volume swept through by the low-pressure piston. An interesting fact was that the realised work was 103·5 per cent. of the whole area G B N J K E H, and if it is left off from both the theoretic and the actual diagrams the piece above M N, which ought to be done, the diagrams give 105·2 per cent. of the theoretic area. That apparently means that some portion of the water found in the cylinder at the pressure 125·4lb. was subsequently evaporated and performed work. He would not go into the question as to how far the jacket lent its aid in effecting this, nor venture to discuss to what extent it is economical or the reverse to allow the engine thus to act as a boiler, but he thought this turns on the source from whence the water came, whether it came from a necessary or an unnecessary source. If it were priming water or excessive initial condensation or the like, it would be very undesirable to see the diagrams bulging out from the evaporation of water that should have been prevented from being there; but if it were the necessary condensation due to the performance of work, or the inevitable condensation due to the cushion steam or the like, then he was of opinion there is economy in getting what work we can out of the water that *must*, from these insurmountable causes, be present in the cylinder. He expected some one would make the usual remark, that if the steam that was put in the jacket had been put in the cylinder instead, more work would have been realised. In this case there was a good answer to that. If the jacket steam had been put in the cylinder so as to have lengthened the line M N, it could not have lengthened that line in any greater proportion to the whole jacket water than the proportion that M N itself bears to the whole feed-water, and when that addition was made to M N, and a new curve thrown down, it would be found that the realised work represented almost precisely 100 per cent. of the new theoretic area. A high degree of economy can only be attained by bringing to one's aid a great number of details all making to one end instead of counteracting each other. The steam must be thoroughly "bottled up" in the cylinder when it is wanted there, as a slight leakage past the valves or pistons is disastrous to economy. He had adopted as a regular principle the common slide valve in preference to the piston valve, not having found it possible to keep the latter quite as tight over long periods as the flat slide. Another condition of economy is that the steam must be supplied to the engine fairly dry; and if dry steam be supplied the greatest care possible is necessary in the design and arrangement of the valves and piston packing rings, or a trouble of a mechanical order will arise.

(To be continued.)

SHIPBUILDING NOTES.

On the 25th ult. there was launched from the yard of the Sunderland Shipbuilding Company, Limited, the steel screw steamer "Wallarah," built to the order of Mr. William Lund, of London. The vessel is of the following dimensions:—Length between perpendiculars, 360ft.; breadth of beam, 43ft.; depth, 29ft. She is classed 100 A1 at Lloyd's, on the three-deck grade. Triple-expansion engines will be fitted by Messrs. Wigham Richardson & Co., of Newcastle. The vessel has been specially designed for the owner's line running between London and Australia.

On the 28th ult. Messrs. W. Doxford & Sons, Limited, launched from their yard at Pallion the fine cargo steamer "Clan Macintyre," built to the order of the Clan Line Steamers, Limited, managed by Messrs. Cayzer, Irvine, & Co., of that city. The vessel is steel throughout, built to Lloyd's 100 A1 class, and her dimensions are:—Length, 312ft. 6in.; breadth, 39ft. 6in.; depth, 24ft. 8in. The engines, which are on the triple-expansion system, were built by Messrs. Doxford, the cylinders being 23in., 37in., 62in., by 42in. stroke, steam being supplied by two large boilers with Howden's forced draught. This vessel is of similar construction to the "Clan Macneil" and "Clan Macleod," just completed by the same builders.

Notices of Meetings.

THIS WEEK.

ROYAL INSTITUTION.—Friday, May 8th, at 9 p.m. Lecture on "Liquids and Gases," by Professor W. Ramsey, F.R.S.; Saturday, May 9th, at 3 p.m., Lecture I., on "The Artificial Production of Cold," by Mr. H. G. Harris, M.Inst.C.E.

INSTITUTION OF CIVIL ENGINEERS.—Friday, May 8th, at 7.30 p.m. Students' meeting. Paper to be read: "Malta Dockyard Caisson," by Mr. J. W. Brown.

PHYSICAL SOCIETY.—Saturday, May 9th. Meeting at Cambridge.

NEXT WEEK.

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.—Monday, May 11th, at 7.30 p.m. Resumed discussion on the following papers: "The Unsinkability of Cargo-carrying Vessels," by Mr. W. Hök; "Water Gauge Fittings for Steam Boilers," by Mr. H. Gray; "The Basis of Ships' Scantlings," by Mr. J. Petree.

INSTITUTION OF CIVIL ENGINEERS.—Tuesday, May 12th, at 8 p.m. Ordinary meeting. Discussion on the paper on "Railway Train Lighting," by Mr. W. Langdon.

SOCIETY OF ARCHITECTS.—Tuesday, May 12th, at 7.30 p.m. Paper to be read: "Timber Piling in Foundations and other Works," by Mr. H. Adams, M.Inst.C.E.

OLD STUDENTS' ASSOCIATION OF THE CITY AND GUILDS OF LONDON INSTITUTE.—Wednesday, May 13th, at 8 p.m. Paper to be read: "Some Researches in Electro-Magnetic Induction," by Mr. E. B. Vignoles.

SOCIETY OF ARTS.—Wednesday, May 13th, at 8 p.m. Paper to be read: "Fast and Fugitive Dyes," by Professor J. J. Hummel. Thursday, May 14th, at 4.30 p.m. Paper to be read: Description of the Growing Uses of Tussur Silk in the European Textile Manufactures," by Mr. T. Wardle.

INSTITUTION OF ELECTRICAL ENGINEERS.—Thursday, May 14th, at 8 p.m. Discussion on the following papers: "On Some Effects of Alternating Current Flow in Conductors having Capacity and Self-Induction," by Dr. J. A. Fleming; "Some Points Connected with Mains for Electric Lighting," by Mr. W. H. Preece, F.R.S.

ROYAL INSTITUTION.—Thursday, May 14th, at 3 p.m. Lecture on "Recent Spectroscopic Investigations," by Professor Dewar, F.R.S.

PRICES CURRENT, 6TH MAY, 1891.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. G. Bailey Toms & Co., London, quote as follows:—

	Com. £ s. d.	Best. £ s. d.	
Middlesbro' Bars	5 15 0	6 5 0	f.o.t. wks.
" Angles	5 10 0	6 0 0	"

"	English Ingots	95 10 0		.....	

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER: A better feeling is observable in copper, with improved demand. During the week a fair amount of business has taken place in Chili bars at steadily advancing rates. To-day's quotations are £51 17s. 6d. to £52 2s. 6d. cash. Manufactured £64, "strong," with more inquiry.

TIN has continued to improve during the past week, and values of foreign are about £1 per ton higher than on the 29th ult.

LEAD has advanced slightly during the last few days.

SPELTER is in better demand, and seems likely to be dearer owing to the labour troubles on the Continent, stocks being small.

PIG IRON—BRAND "CARRON."

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS: There is no change in the position of alkalies. Soda ash continues active. Bleaching powder has a steady inquiry, and caustic soda is rather slow. Crude carbolic is very dull, although the production is considerably reduced, but there is little demand for crystals. Sulphate of copper continues to fall. Acetates of lime are rather pressed for sale. Acetate of soda is more plentiful.

WE have received from Messrs. Barry, Henry, & Co., engineers, Aberdeen, a copy of their new catalogue. In the catalogue, which is very neatly got up, complete particulars are given of gear, spur, and helical wheels, belt and rope pulleys, shafting, couplings, pedetals, edge runners, water wheels, &c.

WILLING'S BRITISH AND IRISH PRESS GUIDE FOR 1891.—This is the eighteenth year of publication of this very useful book, which gives a comprehensive index to all the newspapers and journals published in the United Kingdom, with particulars of each one, as regards the time and place of publication, price, &c. The book also contains a list of the principal colonial and foreign journals published.

Digitized by Google

HOME INDUSTRIES.

LONDON, 7th May, 1891.

THE MONEY MARKET.—Money has been plentiful during the week, and call loans have been fairly easily obtainable. The discount market maintains a firm tendency, there being still some demand for gold for the Continent. The stock markets have been irregular, with a decided inclination to droop. The postponement of the impending Russian Conversion Loan has upset the Paris market, whence the uneasiness thereby produced has spread to London. At the same time New York is troubled by continued shipments of gold, and the boom which seemed so promising has rather come to grief for the time being. The postponement of the Russian Loan has been attributed to serious friction between the Russian Government and its financial representatives abroad, and all Russian securities have consequently declined heavily. All foreign securities gave way in sympathy, and brought down home stocks with them. Americans have been moving irregularly, and, though the undertone is firm, the immediate prospect is a little uncertain. Miscellaneous securities have presented no striking feature. Silver stocks, after a brief rally, have lost ground again with the metal. Mining shares have not been in much favour, with the exception of Indian gold shares.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this company show that the receipts during the month of April were £23,600. The receipts from January 1st to April 30th, 1891, were £88,000, whilst for the corresponding months of 1890 and 1889 they were £81,800 and £84,000 respectively.

THE BOILER REGISTRATION AND INSPECTION BILL.—We observe that the supporters of this Bill, being not overnumerous, have found it necessary to make considerable modifications in it, which will necessitate its being reprinted prior to a further attempt being made to get a second reading on the 17th prox. It would seem that their efforts to enlist the support of the Trades Councils have been entirely unsuccessful, as far as regards Glasgow. As the *Trade Unionist* observes:—"It would be interesting to know on what grounds the Bill can possibly be recommended. What would be thought of a Factory Bill which empowered the manufacturer to select his own factory inspector? Yet this precious Bill of Sir W. Houldsworth, under the pretence of carrying out inspection, makes the steam user, to all intents and purposes, his own inspector."

INSTITUTE OF MARINE ENGINEERS.—A meeting of the Institute of Marine Engineers was held on the 28th ult., Mr. J. H. Thomson, Vice-President, being in the chair. After a digest of Mr. D. McMillan's paper on "Pressures in Compound Engines" had been read, a discussion took place. Mr. Gray and Professor Elliot (of the South Wales University) explained the theoretical considerations in designing engines. Professor Elliot stated that he had found a gain of 20 per cent. in compounding an engine and raising the pressure. Meetings are to be held on the 12th and 26th inst. Papers will be read on these dates. The dinner of the Institute will take place at the Holborn Restaurant on the 20th inst., when the inaugural address will be given by the President, Mr. P. Denny.

THE JUNIOR ENGINEERING SOCIETY.—On the 2nd inst. a large party of members of this Society visited the Tower Bridge works, where they were received by Mr. E. W. Cruttwell, the resident engineer. The steel columns have been erected at the piers and abutments, and the other parts so far pushed forwards that the suspension chains supporting the shore spans will shortly be proceeded with. The fixed girders on the piers, between which the girders of the opening span rotate, have been placed in position. In the north pier the accumulators are being fixed. The masonry, with which the steelwork of the pier and abutment towers is to be surrounded, is stored on the ground, and the setting of it will soon be commenced.

DECIMAL ASSOCIATION.—A joint deputation from the Associated Chambers of Commerce and the Decimal Association will be received by Mr. Goschen and Sir Michael Hicks-Beach on the 8th inst., at 1 p.m., to urge the Government to take the necessary steps for rendering compulsory the adoption of the metric system of weights and measures, now generally adopted in other countries, as the first stage in the introduction of a complete decimal system. The Decimal Association will be represented by the following gentlemen, and a petition, praying for the appointment of a Royal Commission or Select Committee, will be presented to the Chancellor of the Exchequer:—The Right Honourable Sir John Lubbock, Mr. O. V. Morgan, M.P., Mr. Frederick Hendricks, Professor Foxwell, Colonel R. J. Ward, Mr. Stephen Court, Sir Guildford Molesworth, K.C.I.E., Mr. Tom Mann, President of the Dockers' Union, Mr. Frank Debenham, Professor Gladstone, F.R.S., Sir Philip Magnus, Mr. A. D. Provand, M.P., Mr. S. Montagu, M.P., Mr. J. E. Dowson, Mr. F. F. Begg, Mr. A. Siemens, Mr. W. T. Rowlett, Mr. R. A. Hadfield, Mr. W. B. Myers, Mr. H. J. Falk, Mr. J. Rankin, M.P., and Mr W. A. Smith.

BUSINESS ANNOUNCEMENT.—The business of wire rope manufacturing, which has hitherto been carried on by Mr. William Wilkins, at the Wire Rope Works, 39, High Street, Wapping, London, has been transferred to Mr. Gastrill Wilkins and Mr. S. H. Hudston (eleven years with the firm of Messrs. Richard Johnson & Nephew, wire manufacturers). The style of the new firm will be Messrs. Wilkins & Co.

MANCHESTER, 7th May, 1891.

THE THIRLMERE WORKS.—The works connected with the aqueduct for the conveyance of water from Thirlmere to Manchester are making great progress. Only about 600 yards of tunneling requires finishing out of a total length of 14¼ miles; about 9 miles of cut and cover, and 19 miles of pipe-laying also require completion. In all a total length of 67 miles out of 95 is completed. The ironwork is being steadily delivered along the route. The large service reservoir at Prestwich is also nearly completed. It is pentagonal in shape, and has a capacity of 22,000,000 gallons. The inlet is 9ft. in diameter; the beds are of puddled clay covered with concrete and bricks set in pitch, and the banks are stone-pitched.

THE TEXTILE WORKERS AND THE TRADE UNIONS CONGRESS.—At a meeting of delegates from all the chief manufacturing districts in Lancashire, Cheshire, Derbyshire, and Yorkshire, held on the 2nd inst., which was very fully attended, a long discussion took place whether the textile trades should be represented at the Trade Unions Congress. It was finally agreed to recommend all the associations to send delegates, and by a further resolution the raising of the age of half-timers was opposed.

ARSENIC IN COTTON GOODS.—The Consul at Christiana having recently reported that British cotton prints had acquired a bad reputation owing to an excess of arsenic in the pigments employed, the Manchester Chamber of Commerce remitted the subject to the Chemical Sectional Committee for examination. This committee reported that after testing the cloths they found arsenic in dangerous proportions. The use of arsenical compounds was not absolutely necessary, and the same effect could be got in another manner. It was decided to communicate with the Government in order to ascertain what action, if any, should be taken in the matter.

GAS COOKING RANGES.—The Gas Engineering Company of Manchester are placing upon the market a gas cooking range which comprises among its features an automatic flue-damper motion, by which the size of the flue is regulated in exact accordance with the gas consumed. When the doors of the oven are opened the light is automatically reduced, the act of closing them again turning on the full supply. An extra oven heated by the waste heat is also fitted, in addition to the one ordinarily supplied. The cost does not exceed that of the ordinary type of gas stove.

ENGINEERING DISPUTE.—Following upon the settlement of the hours question in Manchester, a dispute is going on in Oldham consequent upon a demand from the men for an advance of 2s. per week. In one or two cases the advance has been conceded, but in most establishments it is being resisted.

ELECTRIC LIGHTING.—A second instalment of what is probably the largest shop installation in the provinces is now under way at Paulden's Drapery Stores, Stretford Road, being found necessary on account of the recent structural enlargements. The original plant consists of a 200 h.p. compound engine driving two 400-light Edison-Hopkinson, four 10-arc Weston, and one 2-arc Gramme dynamos. About three hundred 50 c.p. incandescent and fifty arcs are in place. The new plant comprises a second engine of 130 h.p., three 10-arc Weston machines, and one Edison-Hopkinson dynamo for 1,000 amperes and 100 volts. Three hundred more 50 c.p. incandescents and twenty-two arc lamps are being wired.

THE LINEN AND JUTE TRADES.—Although the home trade has improved, the demand is chiefly confined to fancy goods. The heavy branches, on the whole, are neglected, with the exception, perhaps, of linens. Buyers have placed orders more freely, owing probably to the firmness in Scotch, Irish, and Continental centres of production. The North of England linen manufacturers are fairly well employed. Leeds employs less than 3,000 operatives in its flax mills, but for crashes and other goods of that class local mills have a steady output. The fabrics are stout, and wear well, genuine material being used for both warp and weft. The price, however, is rather high in comparison with the cheaper and, of course, lighter Scotch makes. The shipping trade has improved somewhat, and there is a better demand from Canada, several large buyers being at present in the city. New York and Chicago firms are also operating, and there is no diminution in purchases on account of the high tariff as far as linens are concerned. Fancy Belgian jute tapestry furniture hangings continue to find a ready market in the home trade.

PRINTS AND GINGHAMS.—The sale of prints will, in the near future, suffer considerably from the competition of the coloured woven cotton dress materials known as ginghams. The latter, in fact, are already being shown much more extensively in the local warehouses, as fashion, which has been against them for twenty years or more, has now turned in their favour. The tendency is not very marked, but it is sufficiently distinct to justify the anticipations here made. In the United States ginghams have made much more rapid progress in public favour during the past few seasons.

A NEW CLOTH AND BAG STAMPING MACHINE.—Messrs. Lancaster & Co., of 35, Market Street, are introducing a new machine for stamping names and trade marks on cloth or bags. The machine has been specially designed to suit the requirements of bleachers, finishers, packers, &c. The machine is provided with a self-inking roller, and it is claimed that from 1,200 to 1,500 pieces of cloth can be stamped per hour. The machine can be driven by a small motor.

GLASGOW, 7th May, 1891.

COAL SHIPMENTS.—The coal shipments from Scottish ports, which had been expanding rapidly during the few past weeks, now show some falling off in the rate of expansion. The increase last week was only 800 tons. Glasgow ports, however, show the large increase of 7,000 tons, against a decrease for several successive weeks. The falling off in the increase is said to be due partly to scarcity of tonnage, especially in the west. The falling off is no doubt also due to some extent to the reluctance of buyers to pay the present high prices.

PROPOSED NEW BRIDGE.—At a meeting of the inhabitants of the district north and south of Loch Etive at Connel Ferry, about four miles from Oban, it was decided to initiate a movement for the erection of a bridge at Connel Ferry. The bridge would pass over the curious Falls of Lora, where the incoming tidal waters pass over a gravel bed into Loch Etive, producing the phenomenon of a fall in one direction during the flowing of the tide and in the other during the ebbing. The estimated cost of the bridge is about £20,000. The population of the district is sparse, but the increase of facilities for communication would undoubtedly aid its development.

GOLD EXTRACTION.—Advices from New Zealand report that the Crown Mines Company, a Glasgow enterprise, have made a successful trial of the Cassel process. A crushing of 263 tons of ore yielded 90¼ per cent. of the assayed gold, and 70¼ per cent. of the silver. The value of the product was £6 4s. 6d. per ton of ore, as against £2 per ton by the old battery method. The cost of the extraction is set down by the Crown Mines Company as follows:—Drying, 1s. 6d. per ton; grinding, 5s. per ton; cost of Cassel process, 13s. 6d.—total, 20s. per ton.

OIL COMPANIES.—Messrs. Donald & Co.'s monthly circular on the oil companies states that the Pumpherston Company is expected to pay 10 per cent. dividend, and Young's Paraffin Oil Company 8 per cent. The two dividends declared during April were the Broxburn, 15 per cent., and the Clippens, *nil*. The Broxburn Company has in addition written off a large sum for depreciation—a wise step in a prosperous year. Broxburns have advanced 7s. 6d. during the month, while nearly all the other companies' shares have fallen sharply—Linlithgows, 23s. 6d.; Clippens, 22s. 6d.; West Lothians, 20s.; Burntislands, 10s.; Pumpherstons, 7s. 6d.; Holmes, 6s. 3 l. per share.

MINERALS.—The five blast furnaces at Calder belonging to Messrs. Wm. Dixon & Co., Limited, are now being relighted. Two furnaces were put in blast on the 4th inst., another is being prepared, and the remaining two are expected to follow ere long. New ammonia plant is being re-erected at Carnbrae, one of the works of Messrs. Merry & Cunninghame. The five furnaces at these works will be relighted on the completion of the ammonia plant.

SHIPBUILDING.—Notices have been posted at all the leading shipbuilding and engineering establishments in the Clyde district that piece work wages are to be reduced by 7½ per cent.

GLASGOW CORPORATION.—The Glasgow Boundaries Bill, which settles the long-vexed question of the extent of the municipal area, passed the House of Lords on the 4th inst. —The Corporation appointed a committee to consider the question of electric lighting in the compulsory area under the provisional order granted to the Corporation in accordance with the Electric Lighting Acts. The Town Council will consider the recommendation of their committee within a few days. Sir William Thomson is understood to have advised the Corporation to adopt a low-tension in preference to a high-tension system.

THE LATE MR. ROBERT KINGHORN.—Mr. Robert Kinghorn, J.P., whose death occurred at the end of last week, was for many years connected with the firm of Messrs. Robert Napier & Sons, and was latterly general manager of the London and Glasgow Engineering and Shipbuilding Company, Limited. Mr. Kinghorn, during the half century of his association with shipbuilding on the Clyde, took an active part in promoting the rapid development which was characteristic of the period.

(From our own Correspondents.)

LIVERPOOL, 6th May, 1891.

TIMBER TRADE.—There has been a moderate import during the past month, with a fair consumption. The stocks generally are heavy, and there is a want of buoyancy in the market, with little improvement in prices. The stock of yellow pine is very heavy, and the consumption small, several lots having been sold at very low prices. The stock of red pine is ample for present demands. The stock of oak is very heavy, but the deliveries have been fairly satisfactory. The consumption of elm has been fair, and the stocks are light. There has been a small consumption of ash, and the stocks are heavy. Birch has not been imported, and the stocks are moderate. The arrivals of mahogany consist of 455 logs and curls of St. Domingo, 400 logs and curls Honduras, 209 logs Tabasco, 1,317 Mexican, 119 African, and 16 Panama. There was strong competition at the three sales, good prices being obtained. There is a fair demand for cedar at steady prices.

SHEFFIELD, 6th May, 1891.

THE IRON AND STEEL MARKET.—A fair amount of work is being turned out from the rolling mills and forges. The Association Mills are employed on hire work of special

Digitized by Google

descriptions. A large amount of cycle material is also being made. The file steel trade is not very brisk. Railway material is only in moderate request, Some orders for rails have been received at £4 17s. 6d. Tyres and axles are still quoted at about £12 per ton. The armour plate mills are kept fully employed on heavy plates for the Government, and Messrs. Vickers on the light Russian all-steel plates. Orders for marine work are scarce, and there is little new work in progress. There are a few solid triple-shafts for a Continental Government, but these will soon be completed. Engineers are not well employed, and pattern makers are working short time. The file and cutlery trades are also very quiet. The building trades are brisk all round, and workmen are asking for an advance of ½d. per hour, which will bring their wages up to 6d.

COAL AND COKE.—All descriptions of coal are firm in price. Best coal is at 11s. 6d. in the Barnsley district at the pit's mouth. The demand for London continues good, and with the opening of ports in the Black Sea there has been an increase in the export from this district. Coke is rather easier. The best quality is selling at about 23s. per ton.

LOCAL COMPANIES.—The Staveley Coal and Iron Co., Ld., are about to issue warrants for the payment of a second interim dividend of £3 per share on the A and C shares (£60) and 10s. on the B and D shares (£10). The Parkgate Company are also paying a dividend of 4 per cent.

SHEFFIELD SOCIETY OF ENGINEERS.—A lecture will be given at a meeting of this Society, on the 7th inst., on "English *v.* American Engineering Practice," by Professor J. Goodman, M.Inst.M.E., of the Yorkshire College, Leeds.

A TECHNICAL SCHOOL FOR HALIFAX.—The Halifax Corporation are taking steps to found a technical school. It has been decided to devote the whole of the sum accruing from the Exchequer surplus of last year to the purpose, and several leading local firms have given handsome donations, while the Clothworkers' Company have headed the list with a subscription of £2,000. A total sum of £20,000 is asked for to enable the object to be accomplished.

NEW WATER SUPPLY FOR MORLEY.—The construction of the water works for Morley, from the designs of Mr. Chas. Gott, C.E., of Bradford, is now in hand. A reservoir is being constructed at Withens Clough, with a water area of 63 acres and a storage capacity of 300,000,000 gallons, which is equal to 200 days' consumption of the full supply, in addition to the quantity required for compensation purposes.

NORTH STAFFORDSHIRE, 6TH MAY, 1891.

THE IRON TRADE.—The advance in the price of Scotch warrants is a matter of surprise, and is looked upon as the result of speculative buying, and justified neither by the demand nor the price of finished material. Negotiations have been in progress between blast furnace proprietors and their employés in this district with a view to a reduction in wages, and a final meeting is to be held on the 8th inst., when an arrangement will be made, probably, for a reduction of 10 per cent.

THE COAL TRADE.—Collieries producing house coal still find a large demand. Prices of manufacturing fuel are weaker in consequence of the heavy falling off in demand.

THE POTTERY TRADE.—The arbitration agreed upon for the settlement of the wages dispute will take place during the present month.

LEICESTER, 6TH MAY, 1891.

COAL MINING.—This industry remains remarkably active in this district. Most of the pits are fully employed, and orders are not slow in coming to hand. Prices are very firm in all the better qualities of coal, and no reduction is anticipated before June.

WOOL SPINNING AND YARN TRADES.—Since our last report there has been a small improvement in the business of the local wool market. A fair quantity is changing hands at recent prices, at which quotations the market is very firm. Colonial wools are in good demand, and prices are slightly higher. As a rule, the supply of English wool is small, and there will be no large transactions before the new clip comes in to the market. Spinners are busier than for some time, and in some instances are able to obtain a small advance in prices, but the low rates prevailing for some time past are not easily moved. Lambswool yarns are most in demand. In cashmeres and cotton the trade is not up to the average.

HOSIERY TRADE.—There is only a slow improvement here, the backward spring seriously affecting the placing of season orders.

MIDLAND RAILWAY.—This company are engaged in building a new passenger station here at a cost of over £200,000. There is great activity prevailing on the works, which will be of a heavy character.

SWANSEA, 6TH MAY, 1891.

TINPLATES.—Notwithstanding the decision to bring all the works to a standstill for a month, additions to plant are being carried out in several instances. Another mill has been started at the Pentyrch Works, where for more than a year two mills have been unable to meet the demand. A new engine to drive two more mills and the cold rolls was put into operation last week. At Barry Port a new tinplate works, to consist of four mills, is about to be erected on land which has been secured near Derwydd, belonging to the Earl of Ashburnham, who will be a large shareholder in the new enterprise. Building operations are expected to commence about the end of May. In regard to the stop-month, it is stated that in a few instances the masters have signified their intention of assisting the men by paying them a portion of their wages as if they were working.

CARDIFF, 6TH MAY, 1891.

IRON AND STEEL.—There is a slightly better tone in the hematite pig iron trade, but the business done has been small. Steel rails find a poor market at £4 10s. to £4 15s. per ton, heavy sections. Steel tinplate bars are in moderate request. Iron ore is in better demand, and prices have advanced. Rubio ore is quoted at 13s. 6d. to 14s. c.i.f. Cardiff and Newport, and 14s. 6d. Pathcawl, with 50 per cent. iron as basis.

STEAM COAL AND COKE.—The advance in colliers' wages of 2½ per cent. has come as a surprise even to those who were intimately connected with the trade, and should justify the sliding scale as a correct means for adjustment of disputes between masters and men. The market continues very firm, and shipments during the past week have reached nearly 300,000 tons, which is about the highest amount recorded. Prices remain at for 1st quality steam coal, 14s. 6d. to 14s. 9d.; 2nd, 13s. 9d. to 14s. 3d.; 3rd, 13s. to 13s. 6d.; 4th, 12s. 6d. to 12s. 9d.; first house coal, 14s. to 14s. 9d., and second ditto, 12s. 9d. to 13s. 3d. Coke, furnace, 17s. 6d. to 19s.; foundry, 20s. 6d. to 21s. 6d.; best foundry, 23s. to 25s.

BARROW-IN-FURNESS, 6TH MAY, 1891.

HEMATITE.—A better trade is being done in hematite, and sales this week, both of warrants and makers' parcels, show an improvement. The demand for Bessemer iron has especially increased. Warrant iron has been changing hands at 49s. net cash, and makers are asking 49s. 6d. to 51s. 6d. for mixed Bessemer numbers net f.o.b. During the week the Lowther Hematite Company at Workington has blown out another furnace, and has now only one of their three furnaces in blast. Throughout the district only 39 furnaces are in blast, and 12 of these are at Barrow, while 38 furnaces are standing idle. The stocks of warrant iron this week have been decreased to the extent of over 6,000 tons, and the stocks still held represent 161,000 tons. It is hoped that makers will restrict their output so as further to decrease these stocks.

STEEL.—There is a better trade doing in Bessemer qualities of steel, and some large orders have been recently received. Heavy rails are quoted at £4 12s. 6d., light rails at £5 15s., and colliery sections at £6 10s. per ton. Prices are steady at £6 5s. for ship plates, £6 for angles and other sections, and £6 15s. for steel boiler plates.

SHIPBUILDING AND ENGINEERING.—The need of new orders in the shipbuilding trade at Barrow is fully demonstrated by the fact that the five steamers in hand, and now in course of construction at Barrow, will only afford work for three months. As some of the departments have already completed the work in hand the stagnation is beginning to assert itself. It is expected, however, that new orders of some importance will soon be obtained. The new second-class cruiser "Melampus," built and engined by the Naval Construction and Armaments Company, Limited, Barrow-in-Furness, is now almost completed, and will sail from Barrow in the course of the next week to undergo her speed trials at Portsmouth. The Barrow Company have shown great energy in executing the order they have from the Admiralty to build three of this class of vessels, which were ordered to be built under the Naval Defence Act. Their first vessel, the "Latona," has recently made her maiden run to Gibraltar with great success, a speed of 15 knots having been maintained. The "Latona" is the only ship of her class yet delivered by private builders entrusted with similar orders. Their third vessel, "Naiad" is now having her machinery put on board.

MIDDLESBROUGH, 6TH MAY, 1891.

PIG IRON.—There was a good attendance on 'Change yesterday, and a better feeling prevailed, owing to the large decrease in stocks and the good shipments. Business, however, was quiet, buyers holding back in expectation of prices dropping again. Towards the end of last week Cleveland warrants dropped to 38s. 6d. buyers, and 38s. 9d. sellers, but rose yesterday to 39s. 2d. cash buyers, and 39s. 3d. cash sellers. When the market opened 38s. 9d. was taken in several instances for prompt f.o.b. deliveries of No. 3 G.M.B., but the price soon advanced to 39s. Grey forge is very plentiful, for, though a large quantity is being sent to Scotland, less is being consumed locally. Though 37s. per ton has been taken, 37s. 3d. is the usual price, and even more has been paid for special brands. There is little demand for local hematite, and the price asked is from 51s. to 52s. per ton for mixed numbers.

MANUFACTURED IRON AND STEEL.—There is no change in the prices of manufactured iron and steel, though producers are badly supplied with contracts. Prices are:—Steel ship plates, £6 2s. 6d.; iron ship plates, £5 12s. 6d.; steel angles, £5 17s. 6d.; iron angles, £5 10s.; iron bars, £5 12s. 3d., all f.o.t. at works, and subject to the usual 2½ per cent.

COKE.—Good blast furnace coke has been sold at 13s. and 13s. 3d. delivered.

IRONMASTERS' RETURNS.—The return for the month of April of the Cleveland Ironmasters' Association was issued yesterday, and shows there were 91 furnaces blowing, as against 94 in March, a decrease of three. The make of pig iron for the month was 222,067 tons, compared with 226,544 tons in March, a decrease of 4,477 tons. The stocks of pig iron held are 271,199 tons, as against 289,986 tons in March, a decrease of 18,787 tons. The principal decrease was in makers' stocks, of 13,063 tons, and in Connal's stores, of 4,395 tons. The shipments were 32,405 tons foreign, against 27,522 in March and 59,886 in April last year; while coastwise they were 47,378, against 38,876 in March and 16,420 in April, 1890. The total shipments for April were 79,783 tons, compared with 66,435 tons in March, an increase of 13,348 tons.

SHIPMENTS.—The shipments for this month are still satisfactory, and were 11,340 tons up to the 4th inst.

WORK.—The directors of the Tees Side Iron and Engine Works Company have decided to blow out the two remaining furnaces which they have in blast, as trade has not improved to their satisfaction. This will reduce the output of the district about 11,000 tons.

NEWCASTLE, 6TH MAY, 1891.

THE COAL TRADE.—The local coal trade shows increased activity, and, though the collieries are generally working full time, the output is scarcely equal to the demand. The opening out of North Sea navigation has doubtless contributed to this result, but the labour disturbance in Belgium is also an important factor in the case. The shipments of coal and coke at Tyne Dock during the week ending the 2nd inst. amounted to 112,849 tons, being an increase, as compared with the shipments in the corresponding week last year, of 1,398 tons.

SHIPBUILDING.—The Jarrow and Howden yards of Messrs. Palmer & Co. are now very active, and most of the workmen who have been recently discharged from other local yards through lack of work have found employment at these establishments. Excepting in the instances referred to, slackness becomes more marked each week at the various shipbuilding centres on the river. As builders will be compelled to lower quotations in order to stimulate business, it is probable that a reduction of wages will soon be asked for. It is stated that such a demand has already been made on the Clyde.

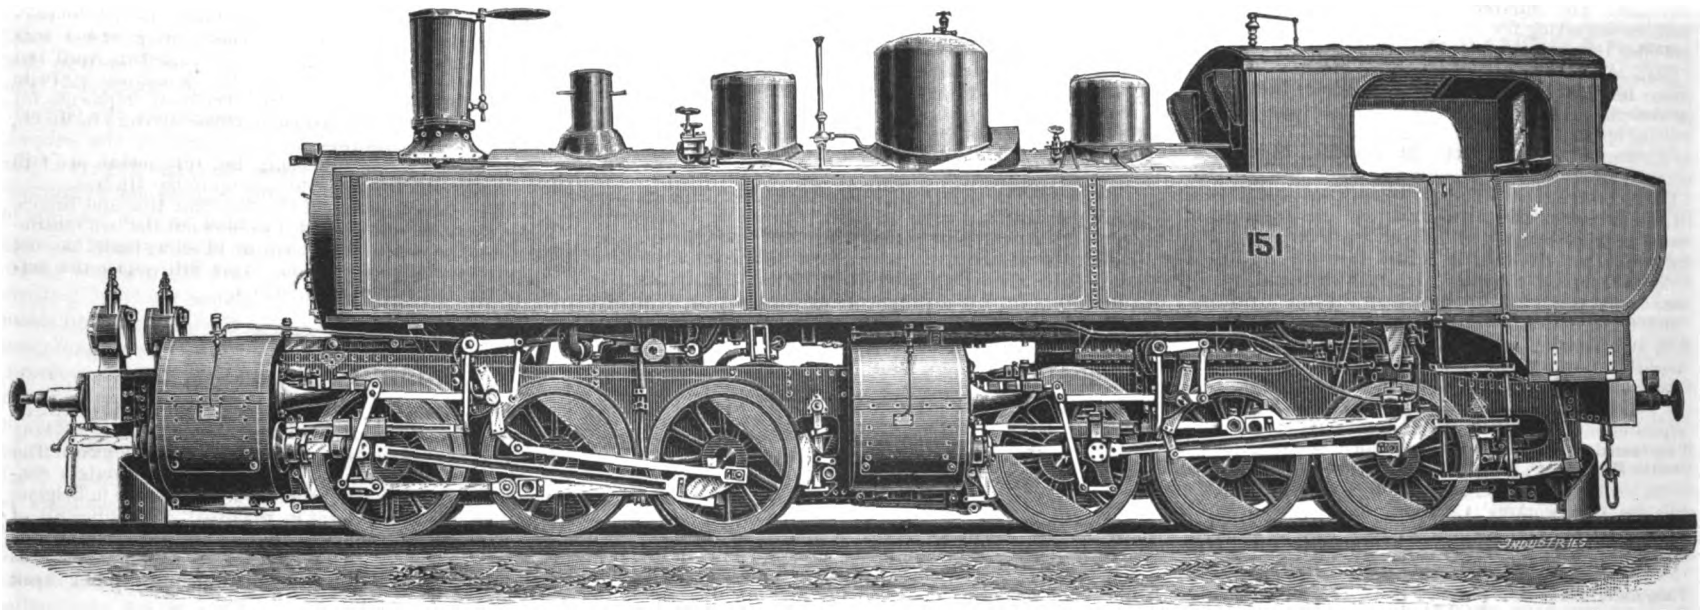
ROPE WORKS.—Rope manufacturers are well supplied with contracts, both for mining accessories and for shipping, and at almost every establishment in the district overtime is being worked. Messrs. Haggie Brothers, wire rope manufacturers, are putting down special machinery in extensive new premises that have been erected near to their present works. The firm are also putting down machinery in a new fitting shop, which is to be principally used for the manufacture and repair of wire rope-making plant.

GAS ENGINES.—Messrs. Fielding & Platt, of Gloucester, have, through their new agency at 36, Mosley Street, Newcastle, just supplied one of their "Fielding" gas engines to a firm at Hartlepool. Inquiries are being received in daily increasing numbers.

LEATHER WORKS.—At many of the leather works business has improved of late, and stocks are being diminished. Messrs. E. & J. Richardson, of the Elswick Leather Works, find a large demand for their specialties in machine belts, bands, hose-pipe, and valves.

ELECTRIC LIGHTING.—The Earl of Durham has decided to thoroughly reorganise the electric lighting arrangements at Lambton Castle. An entirely new electric generating plant, comprising two Cornish boilers, each of 25 n.h.p., and two of Parsons' steam turbines and dynamos of the new improved type, with automatic expansion, each capable of supplying 32 kilowatts, is to be erected by Mr. A. A. Campbell Swinton.

DUNDEE, 6TH MAY, 1891.



JUTE AND FLAX TRADES.—Both branches of the local industry are steady, with a firm market. Jute is strong in all positions, and prices firm. Yarns are selling well, and prices favour sellers. Hessians are steady, but the New York market is rather weaker. Burlaps, 40in. 10¼oz., are quoted at 4 5/16c. per yard, and light weights at 4 3/8c. The flax market is very strong, but transactions are confined to the satisfaction of actual wants. Prices of flax yarns are well maintained, but business is limited, as buyers do not follow the higher prices asked. Manufactories of linens are well employed. Some controversy has been caused by a statement in the Factory Inspector's report, just issued, to the effect that the rate of wages paid in the jute industry is lower than in any other textile industry. It is stated that some firms pay 12s. per week for spinners and 17s. per week for weavers who attend double looms. Weavers are said to earn in some cases from 20s. to 24s. per week.

SEAL FISHING.—The total catch of the Dundee sealing fleet for the season was 88,400 seals, and the value of the oil and skins £40,000.

DUPLEX-COMPOUND LOCOMOTIVE FOR THE ST. GOTHARD RAILWAY.

CONSTRUCTED BY MR. J. A. MAFFEI, ENGINEER, MUNICH.

GENERAL VIEW.

DUPLEX-COMPOUND LOCOMOTIVE FOR THE ST. GOTHARD RAILWAY.

THE illustration given above represents a new duplex-compound locomotive engine, constructed by Mr. J. A. Maffei, engineer, Munich, for the mountain traffic of the St. Gothard Railway. This engine is now doing regular service between Airolo and Bellinzola, and, we believe, to the entire satisfaction of the owners. It will be seen from the illustration that this is a twelve-wheeled tender engine. The axles are fixed to a system of two frames, connected in the middle by a strong joint so that they can form any convenient angle, and thereby adapt the engine for travelling on quick curves. The boiler is fixed to the rear frame and is free to slide upon two heavy support plates on the front frame. The engine is constructed on the compound system, and has four steam cylinders, two of which are high-pressure cylinders, and are fixed to the rear frame, and the other two, low-pressure cylinders, are fixed to the front frame. The steam, after doing its allotted work in the high-pressure cylinders, passes then by means of a movable receiver tube to the two low-pressure cylinders and escapes through another movable pipe to the chimney. The following are the leading particulars of this powerful engine:—

Steam pressure	150lb. per sq. in.
Diameter of high-pressure cylinder	400 millimetres
„ low-pressure „	580 „
Stroke of piston	640 „
Traction power	9,000 kilos
Heating surface of fire-box	9·3 square metres
„ „ boiler tubes	145·7 „
Total heating surface	155 „
Grate area	2·2 „
Diameter of driving wheels	1·23 metres
Distance between buffers	13·776 „
Length between outer wheels	8·13 „
Weight with full equipment	85 tons
Weight without equipment	73 „
Empty weight, approximate	67 „
Water supply	7 „
Coal supply	4·3 „

AMERICAN MAIL SERVICE.

A PARLIAMENTARY Paper has been issued showing the number of days, hours, and minutes occupied by the passages, both outward and inward, during the year 1890, of each of the steamships carrying Her Majesty's mails, between Queenstown and New York, and also between Southampton and New York. The return specifies the names of the steamers and indicates by asterisks those not carrying mails under contract. We imagine that the object of Mr. Leng in asking for this return was to ascertain what effect, if any, the subsidy paid to certain steamers had on the speed; in fact, to ascertain whether, in these days of improved Atlantic service and keen competition, it was any longer necessary to continue the payment of the subsidy. In the returns of the outward sailings, none of the steamers marked with an asterisk carried mails under contract with Her Majesty's Government. In these cases there are no records of the time actually occupied by the sea passage; but the length of passage given in the return shows the time occupied between the delivery of the mails to the vessel at the port of departure and their receipt at the Post Office at New York. There is a considerable variation in the time occupied by both classes of steamers, and there can be no doubt that in many cases the subsidised steamers have the advantage, although some of the newer vessels which are not subsidised run them very close. None of the inward steamers carried mails under contract, and in each case the length of passage given in the return shows the time occupied between the delivery of the mails to the packet at New York and their receipt at the Post Office at the port of arrival, so that in these cases it is possible to arrive at a more correct comparison than in the outward voyages. The paper gives a collection of figures regarding the "Atlantic race" which cannot fail to be interesting to many of our readers, and therefore we have directed their attention to it.

THE SOCIETY OF ENGINEERS.

AT a meeting of this Society, held on the 4th inst., Mr. J. W. Wilson, Jun., Vice-President, being in the chair, a paper was read by Mr. C. C. Carpenter, on "Modern Coal Gas Manufacture." The author commenced by saying that upwards of ten million tons of coal were carbonised annually for gas-making purposes in the United Kingdom. The subject of carbonising was dealt with, reference being made to the shape of retorts best adapted for the purpose, as well as the most suitable settings of them and their construction, the relative advantages of "moulded" and "brick" or "tile" retorts being also considered. The various modes of retort heating by direct or gas furnaces were next explained, reference being made to a system of multiple heated settings introduced by the author in 1886. Charging machinery and inclined retorts was next touched upon, as well as other details of retort-house working. Beale's exhausters for pumping foul gas were illustrated and discussed. The washing and scrubbing plant for the removal of soluble impurities was explained, and the necessity of protecting it from atmospheric changes was pointed out.

Purification by means of lime and oxide was next considered, special reference being made to what are known as "sulphur compounds." The author traced the history of this impurity and described the methods of its removal, stating also how the process depended for its efficacy upon the presence of a percentage of oxygen. The measuring and storing of the purified gas were then explained, as also the development of the large type of modern gasholder, with cantilever framing, originated and perfected by Mr. George Livesey. The paper concluded with a reference to an ingenious invention for dispensing with the ordinary guide framing by means of a spiral roller path formed in the wall of the tank itself.

THE UNITED STATES NAVY.

In a speech recently delivered by President Harrison at San Francisco, he referred to the United States Navy in the following terms:—

"I believe that we have come to a new epoch as a nation. There are opening portals before us inviting us to enter, opening portals to trade and influence and prestige such as we have never had before. We will pursue the path of peace. We do not need a great navy as some other people do; but we do need sufficient first-class ships simply to make sure that the peace of this hemisphere be preserved, simply that we may not leave great distant marts and harbours of commerce and our few citizens who may be domiciled there to feel lonesome for sight of our flag. We are making fine progress with the construction of the navy. The best English constructors have testified to the completeness and perfection of some of our latest ships. In San Francisco the energy, enterprise, and courage of some of your citizens have constructed a plant capable of building the best modern ships. We want merchant ships, and I believe we have come to a time when we should choose whether we will continue to be non-participants in the commerce of the world or now vigorously claim our share in the world's commerce. The Postal Bill marks the beginning of methods to regain that commerce. My belief is that under the operation of that law we shall be able to stimulate shipbuilding, to secure some new lines of American steamships, and increase the ports of call for those now established. It will be my effort to do what may be done under the powers vested in me to open and increase our trade with Central and South America. I am a thorough believer in the construction of the Nicaragua Canal, and I think that influences and operations are now started that will complete that stately enterprise."

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to ensure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 359, Strand, London, W.C.*

FRIDAY, 8TH MAY, 1891.

MARINE ENGINE TRIALS.

THE Report on Marine Engine Trials presented to the Institution of Mechanical Engineers at its recent meeting by the Research Committee, although in some respects more complete than any of their previous reports, was not of such a nature as to add much to our existing knowledge regarding the problems of marine engineering. The Report was a very good example of the applications of the methods which have been found so useful in the case of land engines to those used in steam vessels. These methods, however, are scarcely within the domain of what is usually considered research, as they have become the common property of engineers. Their application to marine engines has, however, been as yet sufficiently rare to justify the Committee in confining their work to what may be called a standard example of finding the efficiency of marine engines and boilers which will serve as a guide to those who wish to follow in their steps. Without wishing to depreciate the work done by the Committee in the past, we venture to express a hope that in the future it will be able to take up the field of research proper, and not only tell us all about the special engines which were the subjects of the experiments, but also extend our knowledge of the general conditions which tend to efficiency. As we pointed out when noticing the previous Report of the Committee (see *Industries*, Vol. IX., page 453), while the past experiments reflect great credit on those who conducted them, they only open up a few of the more important subjects connected with marine engines, and really settle none. Similar experiments must be repeated under varying conditions, so that the effect of boiler pressure, cut-off, steam jackets, speed of piston, and many other factors in steam-power efficiency may be determined. We pointed out, moreover, that one part of the subject, from which almost all experimenters seem to shrink, is the determination of the efficiency of the mechanism of marine and other engines. On this subject we know practically nothing. We are quite aware that all the matters we have mentioned involve much labour and a large expenditure of time and money, but if the work is to be done it ought to be carried out under the superintendence of the Institution of Mechanical Engineers. The economy of marine engines is, however, a work of such national importance that we think the Council of the Institution would be justified in appealing for financial assistance in carrying it out, either from the Imperial Treasury or from the steamship owners of the country. If we consider what an immense amount of money would have been saved if, say, thirty years ago a series of well-designed experiments had been conducted, which would have led to the present practice as regards pressure, expansion, and design, we see that the matter of economy of steam engines becomes a national question in view of the present drain upon our coalfields. The money which is spent on one ironclad, if judiciously employed in experiments on the conditions of efficiency of marine engines, would probably prove a most remunerative investment. We hope, therefore, that the Council of the Institution of Mechanical Engineers will take steps to impress upon the Government or the country the importance of the subject.

As we have already remarked, the Report of the Committee is chiefly useful as a standard example of the methods to be adopted in the testing of marine engines. The value of the report is much enhanced by the diagrams and illustrations given. Such illustrations show at a glance the chief features in the trials, as, for example, the total coal and water consumption, the temperatures of the chimney gases and feed-water, and the total indicated horse-power. Details are also given of the boiler pressure above the atmosphere, the revolutions per minute, and the mean effective pressures in the three cylinders, as well as indicator diagrams from each cylinder. Such a report will be most useful to all students of mechanical engineering, and, no doubt, will find its way into many drawing offices, both of colleges and of works, as a model on which similar reports should be made out. There was nothing special about either the design or construction of the "Iona," although it was a fine example of a modern well-decked cargo schooner with economical engines, of the triple-expansion type, with three cranks working a single screw. The vessel is 275ft. in length, 37ft. in breadth, and 19ft. in depth, and her registered tonnage is—gross, 2,094 tons; under deck, 1,610 tons, and net, 1,348 tons; and she is classed at Lloyd's 100 A1 (special survey). The trial was conducted with great care, and lasted for sixteen hours. The speed of the engine was not altered during the trial, nor was the valve gear touched or altered during the whole time. In addition to all the observations which had been taken on former trials, indicator diagrams were taken at intervals from the circulating and air pumps, from the first and second receivers, and from both ends of the condenser. The temperatures of the circulating water and the discharge water were also noted; and the jacket-water, steam pipe drain-water, and supplementary feed-water were each separately measured. We only mention these in a general way for the purpose of showing the care with which the experiments were carried out, for we must refer to the Report itself for details. This we reprint on page 448, and in it will be found descriptions of the engines and boilers, and of the methods of conducting the experiments, of collecting the furnace gases, and making the necessary measurements of the quantities required. We cannot enter into these, but can only note a few of the results. With regard to boiler efficiencies, the mean rate of combustion in the furnaces was 22·41lb. of coal per square foot of actual grate surface per hour, or 0·30lb. per square foot of total heating surface per hour. The evaporation from and at 212° Fahr. was 10·63lb. of water per lb. of coal, and the equivalent amount of heat utilised per lb. of coal 10,265 thermal units, or 69·2 per cent. of the thermal value of the fuel, and this latter figure represents the actual boiler efficiency. The weight of air theoretically necessary for the complete combustion of 1lb. of coal is 11·41lb. The air actually used was 2·15 times the amount theoretically required. The weight of water evaporated from and at 212° Fahr. per square foot of total heating surface was 3·17lb. per hour. The total coal burnt—namely, 942lb. per hour—corresponds to 1·46lb. per indicated horse-power per hour. The total indicated horse-power being 645·4, and the total feed-water used per hour being 8,616lb., the feed-water used per indicated horse-power per hour was 13·35lb. The

Digitized by Google

actual heat received by the feed-water per minute was 161,100 thermal units, or 249·6 thermal units per indicated horse-power per minute, which is 69·2 per cent. of the whole heat of combustion. The absolute engine efficiency, or ratio of the heat turned into work, to the heat given to the feed-water was 17·1 per cent. The combined efficiency of the boilers and engines, or ratio of the heat turned into work, to the total heat of combustion of the fuel was equivalent to 11·8 per cent.

These results are very satisfactory as regards the special engines under consideration, but we hope that the Research Committee of the Institution of Mechanical Engineers will enlarge the scope of their investigations. We trust that their future reports will not only give details of performances of special engines, but also help to extend our knowledge of the conditions of efficiency of marine engines in the manner which we have indicated.

THE NEW BATTLE-SHIP "RENOWN."*

The launching of the first-class battle-ship "Renown" was successfully carried out at Pembroke Dockyard yesterday, the 7th inst., the christening ceremony being performed by Her Royal Highness the Duchess of Connaught. The "Renown" is the second of a class of eight battle-ships built and building under the Naval Defence Act of 1889, which were specially designed to take part in general fleet actions in European waters. The leading dimensions of the "Renown" are:—Length, between perpendiculars, 380ft.; breadth, extreme, 75ft.; mean draught of water, 27ft. 6in.; and displacement at this draught, 14,150 tons, which surpasses that of any other ship in the navies of the world. Previous to the launching of the "Royal Sovereign"—a sister vessel—which took place at Portsmouth in February last, the largest warships in the British Navy were the "Nile" and "Trafalgar," each of 12,500 tons, and these were largely exceeded in displacement by the "Italia," of 13,900 tons, and the "Lepanto," of 13,550 tons, belonging to the Italian Navy.

The "Renown" is built throughout of mild steel, the stem and stern post, together with the shaft brackets, being of cast steel. Steel-faced armour, having a maximum thickness of 18in., extends along the sides for 250ft. amidships, the lower edge of the belt being 5ft. 6in. below the normal water-line. The belt is terminated at the fore and after ends by transverse armoured bulkheads, over which is built a 3in. protective steel deck extending to the ends of the vessel and terminating forward at the point of the ram. Above the belt the broadside is protected by 5in. armour, the central battery being enclosed by screen bulkheads of the same thickness. The barbettes, which are formed of armour 17in. thick, rise from the protective deck at the fore and after ends of the main belt. The principal armour throughout is backed by teak, varying in thickness from 18in. to 20in., behind which is an inner skin of steel 2in. thick. The engines are being constructed by Messrs. Humphreys, Tennant, & Co., London, and are of the vertical triple-expansion type, capable of developing a maximum horse-power of 13,000 with forced draught, and 9,000 horse-power under natural draught, the estimated speeds being 16 and 17½ knots respectively at the normal displacement. The regular coal supply is 900 tons, which will enable the ship to cover a distance of 5,000 knots at a reduced speed of 10 knots, and about 1,600 knots at her maximum speed. The main armament of the "Renown" will consist of four 67-ton breechloading guns mounted in pairs *en barbette*. The secondary armament includes ten 6in. 100-pounder quick-firing guns, four being mounted on the main deck and six in sponsons on the upper deck, sixteen 6-pounder and nine 3-pounder quick-firing guns, in addition to a large number of machine guns.

The largest guns at present mounted in any British warship are the 110-ton guns mounted in the "Benbow" class, and the difference between these weapons and those to be carried by the "Renown" is very marked. The projectile fired from either of the "Benbow's" heavy guns weighs 1,800lb., and is capable of penetrating 35in. of unbacked wrought iron at a distance of 1,000 yards. The projectile fired from the 67-ton guns of the "Renown" will have a much less penetrating power, being only equal to 27in. of wrought iron, with a full charge of 520lb. of prismatic brown powder, the missile weighing 1,250lb., or about one-half less than the weight of the shot used with the 110-ton gun. It will thus be seen that the ordnance of the "Benbow" can penetrate armour that would defy the attack of the guns of the "Renown." It should be said, however, that the heavy artillery of the latter vessel is capable of penetrating any armour at present afloat, and is carried at a much greater height above the designed load water-line than in any existing battle-ship, either in the British or foreign navies. The armour being of less weight, too, enables the new ship, and others of her class, to carry an auxiliary armament of unprecedented weight and power.

The "Renown" will be lighted throughout by electricity, the installation comprising some 600 lights, and will be provided with four 25,000 candle-power search lights, each of which will be worked by a separate dynamo. The "Renown" has been built from the designs of Mr. W. H. White, C.B., Director of Naval Construction, and will be fitted out for the use of an admiral, and when commissioned her complement of officers and men will number 700.

Table I. gives the leading particulars of the "Renown," summarised for comparison with the "Trafalgar" and the larger foreign battle-ships.

* We learn, on going to press, that the name of this vessel has been altered to the "Empress of India."

COMPARISON OF BRITISH AND FOREIGN BATTLE-SHIPS.

TABLE I.

Name of ship	Renown.	Trafalgar.	Italia.	Admiral Duperre.	Sinope.	Coast Line Battle-ships 1, 2, 3.
Nationality	British	British	Italian	French	Russian	American
Date of design	1889	1885	1877	1876	1883	1890
Length between perpendiculars	380ft.	345ft.	400ft. 6ft.	311ft.	300ft.	348ft.
Breadth	75ft.	73ft.	72ft. 9in.	66ft. 11in.	69ft.	69ft. 3in.
Draught, mean	27ft. 6in.	27ft. 6in.	31ft. 3in.*	26ft. 9in.*	26ft.*	24ft.
Displacement, tons ..	14,150	12,500	13,900	11,100	10,800	10,298
I.h.p., maximum	13,000	12,000	18,000	8,000	13,000	9,000
Official speed, knots ...	17·5	16·5	18·0	14·2	16·8	16·2
Coal capacity at designed draught	900	900	1,600	—	890	400
Coal endurance at a speed of 10 knots ...	5,000	5,000	—	—	—	3,600
Armament, main	4 67-ton B.L.	4 67-ton B.L.	4 100-ton B.L.	4 47-ton B.L.	6 50-ton B.L.	4 13in. B.L.
Weight of projectile, heaviest, lbs.	1,250	1,250	2,002	926	732	—
Maximum thickness of armour, inches	18	20	—	21·5	16	18

* Extreme draught.

CONTINENTAL LABOUR.

May Day has come to be a kind of labour festival on the Continent, when agitators and their followers meet together and demonstrate in a noisy, and sometimes in a violent, manner. The dread with which the Continental Governments, alike Imperial and Republican, regard these demonstrations is scarcely realisable in this country, where we are habituated to such methods of letting off the steam, which, pent up, might lead to explosion. The existence of discontent among Continental labourers is not without important influence upon our own country, since to some extent, at any rate, our merchants are met in foreign markets by wares made by poorly-paid Continental labour, while our own industries are invaded by foreigners seeking in this country a larger rate of remuneration than they can obtain in their own. Thus, although it is no doubt distressing to read of perpetual bickerings and occasional conflicts between Continental employers and their workmen, there is no doubt that Continental labour has to make many strides before it reaches a platform of anything like so great equality for making a contract for employment as the British workman attained long ago. From several points of view it is important to us that Continental labour should be fairly remunerated. Even from the purely commercial standpoint, it is quite clear that a nation whose working class is living at a depressed standard of comfort is a less advantageous customer to us than a nation the bulk of whose people live at a high standard and consume largely. For the very reason that the cost of production of commodities does not altogether govern the prices of these in the market, the prices of some of our products are depressed by the products of cheap labour abroad. Therefore, from the point of view of competitive commerce, it is to our interest that wages abroad should be as high, and the standard of comfort as elevated, as are those of our own working class.

While movements primarily of a purely economic character are often manipulated in such a way as to convert them into subversive political movements, it is open to doubt whether the repression of public demonstrations and such other safety valves is a wise policy on the part of Continental Governments. The incident at Fourmies, described as a "massacre," in which, at all events, several unarmed men, women, and children were shot down by the French troops, is, if the facts be as stated, indefensible from any point of view. No doubt the officers on the spot, rather than the Government, were to blame, and no doubt also the exercise of large discretionary powers must be left to the officers commanding troops detailed to maintain order; but the risks on all hands are too great for a Government to afford many military blunders of this kind.

Sooner or later, the advantages of public meetings, demonstrations, and the like, as highly necessary outlets for the discontent of large populations, must be recognised abroad. When these methods are no longer so discredited that they are apt to be attended only by those with a certain tendency to violence, and when even the most conservative among the working class attend them, and so leaven the lump, they will cease to be regarded by the fear with which, not always unreasonably, they are now regarded abroad.

IMPROVED COMMUNICATION WITH THE EAST.

In our last issue we referred to the quick passage made by the new steamer the "Empress of India" between Yokohama and Vancouver. On the arrival of the steamer at Vancouver the passengers were transferred to the Canadian-Pacific express train for Montreal. The run from Vancouver to Montreal, a distance of 2,900 miles, was made in three days seventeen hours, whereas the time usually occupied is six and a half to seven days. The average speed for the entire distance was 34 miles an hour. Owing to this splendid performance, the time occupied in the journey from Yokohama to Montreal is brought down to two weeks, and it is expected to bring London within three weeks' journey from Yokohama. The performance of the Canadian-Pacific train is really an excellent achievement on the part of the railway company, which will in future run a similar train to carry the mails from Great Britain to China and Japan, and *vice versâ*. These mails will thus be conveyed in a much shorter space of time than by any other route.

THE "CITY OF PARIS."

The "City of Paris," which sustained severe damage to her machinery last year, has been, during the past four or five months, in the hands of her builders, Messrs. J. & G. Thomson, of Clydebank. New engines have been fitted to replace those damaged, a new shaft has been made, and Howden's system of forced draught has been introduced. The vessel has, besides, been thoroughly overhauled, and the passenger accommodation redecorated. Notwithstanding delay in obtaining the necessary supply of steel, the builders have succeeded in completing

Digitized by Google

the extensive alterations in an extremely short time. As is well known, the engines are 10,000 i.h.p. The shafting has been supplied by Messrs. Vickers & Co., Sheffield, and several important improvements have been introduced. An appliance, devised by Messrs. Brown Brothers, of Edinburgh, the well-known hydraulic engineers, has been introduced in order to effect the automatic stopping of the engine should the normal number of revolutions be exceeded. A gauge has also been fitted for the purpose of enabling any undue wearing of the shaft to be promptly detected. At the trial on the measured mile, preliminary to a Channel cruise, the mean speed attained was 21·048 knots. The mile was covered with the tide twice in succession in 2 minutes 48½ seconds, and against the tide twice in succession in 2 minutes 55 seconds. In the Channel trial, a distance of 500 miles was covered at an average speed of 19½ knots.

The vessel commences her sailings from Liverpool to New York on the 13th inst.

Letters to the Editor.

THE SINKING OF THE "BLANCO ENCALADA."

To the Editor of "Industries."

Sir,—The political questions raised by your correspondent, Mr. Alfred E. Mavor, are, of course, beyond the scope of the discussions carried on in a technical journal, and, therefore, I will not touch upon them, but such a matter as the sinking of an ironclad by torpedoes should receive the attention of all who are interested in the design and construction of ships. The behaviour of ironclads in a battle is almost an unknown quantity, for, beyond the small experience in the Austro-Italian and the Russo-Turkish wars, naval constructors and officers have almost nothing to go upon. Mr. Mavor remarks that torpedo warfare has probably been more extensively and more fatally practised on the West Coast of South America than anywhere else, and that the Chilians and Peruvians have both proved themselves to possess, at least in attack, all the vigilance, resource, and ingenuity upon which these are dependent. The present example, I am afraid, seems to show that the officers of the "Blanco Encalada" were wanting in vigilance. Whether it will afford any other lessons it is still premature to say until we have got more particulars. No one, of course, doubts that it is possible for an ironclad to be sunk by torpedoes if the former is at rest, and not defended with vigour.

We are told that the ironclad was moored to the quay in Caldera Bay, when it was surprised by torpedo boats, and only on the seventh attack did the latter succeed in destroying the vessel. The sinking of the ironclad under these circumstances is not at all surprising, but what I would like to know about torpedoes is how far they are a match for quick-firing guns carried by a vessel under steam. Mr. Mavor thinks that if the vessel had been at sea, and could have chosen a duelling ground with two cruisers, we should have had news of a different tenour. That, however, is scarcely the question raised by the incident. It is not how far one ironclad can defend itself against other ironclads, but what part ironclads are to take in the naval warfare of the future—in fact, the whole policy of building ironclads is involved in the matter. Perhaps Mr. Mavor, who seems to have had some South American experience, or some of your other readers, will favour us with opinions on the subject.

Yours, &c.,
Torpedo.

London, 4th May, 1891.

ENGINEERS IN THE ROYAL NAVY.

To the Editor of "Industries."

Sir,—I do not think that much good will come from continuing a correspondence with your Portsmouth correspondent "A. E.," as he seems determined to misunderstand both your own article and my letter. So far as I understand your article you did not propose that the main supply of engineers for the Navy should come from the engine-room artificers, you simply suggested that an avenue ought to be opened up whereby *at least the best of them* might be able to obtain the position of engineer officers. With regard to the officers, you said that "when we consider how little mathematical knowledge is required by sea-going engineers, we think a test might be devised which would secure the best men for the work to be done," and you added that "you did not think that this is likely to be the case if a knowledge of pure mathematics, or even physics, is to be preferred to good workshop practice."

I have no hesitation in saying that there are hundreds of young men who now serve their apprenticeships in engineering workshops who would make excellent engineer officers, and who are excluded by the requirements regarding theoretical knowledge. If the service were open to such men, many of them would be willing to serve a year or two at sea for the purpose of gaining some experience, and their conduct during that year would be the best test of their fitness for the service. If that experience was recognised as qualifying for the first examination of the Board of Trade, the probationers could then decide whether they prefer to remain in the Navy or go to the mercantile marine, or possibly return to some land employment. Those who decided for the Navy should be required to pass a comparatively simple examination, while those who passed a higher one might be offered some advantages as regarded their start in the service. Teachers have been too much in the habit of looking upon their classrooms as the centre of the universe, and mathematicians of considering their special training as the one thing needful. The President of the British Association, in his address last year, attempted to warn his hearers on this subject. He said, "However much we may be convinced of the supreme value of scientific methods of observation and of reasoning, both as mental training of the individual, and in the elucidation of truth and advancement of knowledge generally, it is impossible to be blind to the fact that we who are engaged with the investigation of those subjects which are commonly accepted as belonging to the domain of physical science are unfortunately not always, by virtue of being so occupied, possessed of that most precious gift 'a right judgment in all things.'"

In this, indeed, he was correct, and my only reason for troubling you was for the purpose of indicating a method by which the Navy might obtain a good supply of good practical engineers, who have a right judgment in—if not all—at least a good many things, and who also had sufficient theoretical knowledge for the due performance of their duties. As, however, every service should have men of varied characters, I think it desirable that those who showed special aptitude for mathematics and science generally should receive every encouragement to develop them, in so far as that is advantageous to the work of the service.

Yours, &c.,
Glasgow, 5th May, 1891. M.I.N.A.

TRIAL OF H.M.S. "VULCAN."

To the Editor of "Industries."

Sir,—In your account of the trial of H.M.S. "Vulcan" you refer to the three Willans central-valve engines for electric lighting, which this ship carries, and mention the claim made that these engines and dynamos develop an electrical horse-power for 29lb. of water per hour—and you add the words, "which is a remarkably good result."

Will you allow us to say that an important qualification is omitted in these figures? 29lb. is the consumption *at the steam pressure named in the specification*—viz., 100lb. per square inch; and when exhausting into the atmosphere. With similar engines and dynamos there is no difficulty in obtaining an electrical horse-power upon less than 25lb. of water per hour, if the steam pressure is 140lb. or upwards; and if the exhaust be into a good vacuum, instead of into the atmosphere, the consumption falls to about 19lb. The pressure actually available in the boilers of the "Vulcan" is, as you state, 150lb.; and we believe arrangements are made for discharging the exhaust from the electric light engines into a condenser. The Admiralty, however, naturally specifies what it assumes to be the least favourable conditions the engines may have to work under; and the statement of consumption of course follows the specification in this respect. It may be added that the dynamos are of Messrs. Siemens Bros.' make, and are of a pattern with which we rarely fail to obtain a total efficiency of 82 per cent. from the engine and dynamo combined.

A similar set will, in a few days, be running in the Central Lighting Station at the Naval Exhibition, in the same building with the three large central-valve engines of 300 indicated horse-power each by which the Exhibition and grounds are lighted.

Yours, &c.,
Willans & Robinson, Limited.
(C. S. Essex, Secretary.)
Picton House, Thames Ditton, Surrey,
5th May, 1891.

THE NICARAGUA CANAL.

To the Editor of "Industries."

Sir,—The interesting and important articles which are appearing in *Industries* on "The Nicaragua Canal" come at a very opportune time, when the Government of the United States is making special efforts to expand the trade of that country, and practically to monopolise the whole of the foreign commerce of South America. Our manufacturers and merchants must keep their eyes open, not only with regard to the daily or weekly variations of the markets, but they must look ahead and try to ascertain how far engineering or other conditions are likely to affect both its amount and direction. The other day President Harrison expressed the opinion that the United States were now great enough and rich enough to reach forward to grander conceptions than have entered the minds of their statesmen in the past. Personally, he said that he was not content that the nations of Europe should absorb nearly the entire commerce of the Republics of South America. This commerce was naturally theirs by neighbourhood, nearness of access, and the sympathy that binds the hemisphere which is without a king. He mentioned with approval the treaties which had been made with Brazil, and stated that he was not disclosing any Executive secret when he said that the arrangement with Brazil was not likely to abide long in lonesomeness, that other countries are likely to follow, and that, as a result, the products of the United States will find free or favoured access at many of the ports of the South or Central American States. To carry American goods to these ports they would need American steamships, and to encourage the production of these Congress had made very liberal provision. He much wanted the time to come when the citizens of the United States living in temporary exile in foreign ports should now and then see fine modern men-of-war flying the United States flag, with the best modern guns on their decks, and brave American crews in their forecastles. He wished also that in those ports so long unfamiliar with the American flag there should again be found their steamships and sailing vessels flying that flag and carrying their products. He added that in order to accomplish this they ought to make individual efforts for the early completion of the Nicaragua Canal, for he was strongly of opinion the Pacific Coast should no longer be reached by sea only by the passage round Cape Horn.

Your articles have given an interesting historical sketch of the proceedings connected with the Canal, and also of the attitude of the United States Government at various times towards it. President Cleveland repudiated the proposed treaty with Nicaragua, which had been drawn up under his predecessor, and, while wishing to encourage the scheme, he thought it should be done without involving any political engagements, and entirely as a piece of private enterprise. President Harrison's opinions on this point have not been definitely stated, but the subject is attracting very considerable attention in the United States press at the present time, as it is felt that no other measure of public policy now submitted is of such wide-reaching importance, and Government aid is strongly advocated. At another time I may, with your permission, briefly indicate some of the commercial effects of the Canal, if it were completed, not only on the United States, but also on Europe, and especially on this country. The study of questions of this kind tends to give our merchants greater breadth of view, and enable them to follow some of the most important movements in commerce.

Yours, &c.,
C.E.

Liverpool, 2nd May, 1891.

THE USE AND ABUSE OF MATHEMATICS.

To the Editor of "Industries."

Sir,—After reading the letters you have already published upon this subject, my belief has been strengthened that the value of an opinion depends to a very large extent upon who gives it, and hence that the value of your contributions to your general readers would be increased, could your contributors convey more information as to the nature of their own engineering experience and work. If this was done, I venture to think you would find the abuse of mathematics as a part of an engineer's training would come only from those who possess no personal knowledge of that subject, and hence regard it very much as "sour grapes," while those who had attained to some mathematical powers would be unanimous as to its use. Of course, it will be understood that I speak here, not of that ethereal mathematics which delights to speculate in four dimensions, or examine the greatest possible height to which a tree can grow, but of that mathematical knowledge which can be brought to bear upon actual engineering work. It can give exact results instead of approximate ones, and can displace the rough-and-ready rule of adding certain numbers together and dividing by two to make quite sure, by a method at once sound and educational. Moreover it can anticipate results without costly experiment, or decide with speed and certainty a result otherwise only obtainable by a laborious and costly system of trial and guess-work. In connection with this, is it not a fact that Sir W. Thomson first demonstrated mathematically the possibility of the first Atlantic cable, before practical men would undertake its construction?

I know of only one thing more remarkable than the confidence of the non-mathematician in his own method of "near enough," and his satirical contempt of exact investigations; and that is, the eagerness with which he will afterwards secretly endeavour to master the mathematical method for himself, and his after merciless criticism of those who do not share his newly acquired knowledge. The memory of my own want of sympathy in my very practical days with the "pedantic college man" in his distinctions between "mass" and "weight," "empirical" and "true" formulæ, is still fresh upon me, as is also the satirical opposition I have not infrequently met with since I have recognised that certain words or phrases should possess one meaning only, and have besides parted with my "Molosworth." Then, I could quite cheer the definition of an empirical formula as being founded upon knowledge, and a theoretical formula upon the want of it; whereas now, having proved something of the use of mathematics for myself, I am able rather to exactly reverse this statement. And I think you will find this to be a very general experience.

The more I see and know of engineers and their profession the more I become a believer in the importance and use of mathematics, and the more I regret that, instead of giving seven years to my practical training, I did not devote a large part of that time to a comprehensive study of applied mathematics. Am I not also right in finding a strong support for this belief in the fact that the leading positions in the engineering world are now being given to men who are distinguished among their fellows, not for their practical ability, but as possessing a sound theoretical and mathematical training? The names of several of these have already been given in the course of this discussion, and who can have failed to notice the increasing demand among large firms for "theoretical advisers"? Professor Kennedy now ranks as a chief among consulting engineers, and he has upon his staff at least one man who was among the first twenty in a recent mathematical tripos at Cambridge.

It was my good fortune to gain my drawing office experience in the works of an engineering firm of world-wide reputation, which kept a staff of about twenty draughtsmen. No one could say they ever abused mathematics, or *used* it. I never remember seeing a book of logarithms in use, which meant, I suppose, that the power of logarithms was unknown, while little problems such as required the finding of the third side of a triangle, knowing the others and their included angle, could only be solved by actual drawing. Another instance I still marvel at, where a draughtsman in another well-known and respected firm came to me for assistance in finding the actual length of the curved part of a cast piece, shaped to a sector of a circle, the radius and included angle being known. I say nothing against the ability of these men to capably design machinery under given conditions and with given examples of similar construction, but no one will assert they would not be better for some knowledge of workable mathematics, and at least we may expect the next generation, hailing from our technical colleges, will possess more power.

Mathematics, then, must be used before it can be abused, and I am not sure that professional critics are not too ready to discover abuse, forgetting the importance of its greater use. The tendency of modern technical training is to increase the latter, and many examples are now to be found of capable mathematicians willing to break through the antiquated notions of how the various parts of mathematics should be approached, the result of which generally was that they were never approached at all, and to bring down within the scope of the ordinary mathematical student its most useful properties. If they show clearly the limits of its application to practical problems, and keep distinct the right analogy between conditions that arise in actual construction and their theoretical counterparts, and generally impart a sound knowledge of how to use theory in practice, we need not be fearful of the result. Mathematics is absurd when a laborious and advanced calculation is used to solve a problem which can be answered even beyond practical needs by some simple method of approximation, or when long formulæ are placed in the hands of those who do not understand them, or forced upon unwilling and unsuitable students, but engineers at present most of all abuse it by not using it.

Yours, &c.,
Engineering Demonstrator.

London, 2nd May, 1891.

THE ROYAL SOCIETY CONVERSAZIONE.

The first conversazione of the present session was held on Wednesday evening, the 6th inst. The exhibits were not probably so numerous as on previous occasions, but the very latest forms of scientific apparatus were shown, and demonstrations of the latest features of scientific research were watched with interest.

Mr. Crookes exhibited some very beautiful and striking experiments with electricity in high vacua, especially in the production of phosphorescence. Among a variety of other electrical exhibits we may mention the various self-recording instruments of MM. Richard Frères, an electrical safety valve by Mr. Killingworth Hedges, various adaptations of selenium by Mr. Shelford Bidwell, and some forms of Clark cells by Professor A. Schuster. The Tomlinson regulator for electric light mains was exhibited by Messrs. J. E. H. Gordon & Co. Professor Oliver Lodge exhibited some new electrical apparatus.

Among the non-electrical exhibits there were several of practical value and scientific interest. Mr. A. P. Trotter exhibited a curve ranger which is a portable instrument intended to facilitate setting out large curves for railway and other work. Professor Roberts-Austen exhibited his method of recording pyrometric measurements at temperatures between 600° and 1,200° Centigrade.

The great show of the evening, however, was the very beautiful and instructive series of meteorological photographs (clouds, hoar frost, &c.), thrown on the screen by means of the electric lantern, by Mr. Arthur W. Clayden. The photographs of clouds were taken by reflection from a mirror of black glass placed in front of the camera, so that the plane of its surface makes the polarising angle with the axis of the lens. Every variety of cloud was thus brought into clear prominence on the screen. The exquisitely beautiful photographs of hoar frost showed how the crystals attach themselves to the projecting portions of objects, such as the margins of leaves, the loose fibres of a string, and the thorns of a briar, and also their tendency to grow towards the direction from which the air has been moving.

We hope to refer more at length to the exhibits in our next issue.

THE IRON AND STEEL INSTITUTE.

The annual meeting of the Iron and Steel Institute was opened on the 6th inst., at the Institution of Civil Engineers, Sir James Kitson, President, being in the chair. In moving the adoption of the report, he referred to the memorable occurrences of the last two years—first the visit to Paris, and then that to America. The difference between American blast furnace practice and their own was very marked, but though the Americans produced more pig iron, yet they did it under certain disadvantages in spite of the lower price of coal and coke. The Institute during the last year had been prosperous, and a larger number of members had joined them than they ever had before; in fact, the increase during last year was equal to the number that the Institute had started with during its first year of existence. They had suffered several regrettable losses, notably by the deaths of Lord Granville, Mr. Mushet, and Mr. Benjamin Walker. It is proposed to hold the autumn meeting in Birmingham.

After the usual formal proceedings, Sir James Kitson vacated the chair in favour of Sir Frederick Abel, the incoming President, who proceeded to deliver his Presidential Address. Referring to the important position gradually assumed by the chemist and analyst, he mentioned the great impetus given to their subjects by the investigations undertaken after the Crimean War into ores and metal for ordnance purposes. Ever since the analyst has been indefatigable in his endeavours to improve the manufacture of iron and steel, and the latest development of the question is the appointment of a Committee to consider the general question of analysis, and to make standards for future reference. Microscopic examination in connection with etched surfaces has been extensively worked at, and results have been attained which agree, as pointed out by Professor Roberts-Austen, with Osmond's researches. This method is now largely employed in Germany, and is still under the consideration of many scientists. As early as 1865 he had used etching in connection with an investigation of the application of steel to solid shot. In the first specimens, violent rupture of the shells often occurred, due to the internal strains set up on cooling, and even now this often takes place. The importance of *rest* in bringing about a diminution, if not the entire disappearance, of internal strains in masses of metal, is illustrated by the behaviour of chrome-steel projectiles, which—at any rate in the earlier days of their manufacture—it was found necessary to store for several months before their transport to a distance could be ventured upon. Since steel was first adopted for the internal tubes or chases of guns, some few casualties have occurred which can only be ascribed to the same cause. Oil hardening and subsequent tempering do much to relieve these strains, and the tempering is effectual if cracks did not exist previous to that operation.

The President then referred to the use of silicon and the careful blending and remelting of pig iron for producing sound and uniform castings. The elimination of phosphorus in the open hearth furnaces and in other processes was dealt with, as an example showing the complexity of the chemical problems which present themselves. As bearing on the further development of the basic process, the Darby recarburising process and American blast furnace practice were cited. The chemical composition of steel for ordnance, at the present time, is not prescribed by the Government, as the modifying effects of varying proportions in which several impurities co-exist in the metal is not understood. Nitrogen in iron and steel received some notice, and Osmond's researches on the constitution of steel then occupied some time. The similarity in the behaviour of other metals containing small traces of impurities had, he said, steadily expanded the functions of the Institute, so that in time it might be transformed into the "Metallurgical Institute of Great Britain."

A large part of the address was given up to a summary of the recent knowledge of the effect of aluminium, silicon, manganese, and nickel on iron and steel, reference being made to the researches and papers of Riley, Hadfield, Keep, and others. In connection with nickel-steel and the supply of nickel, it was suggested that the recent discovery of a gaseous compound of nickel and carbonic oxide might form the basis for a metallurgical process of extraction.

After the conclusion of his address, the President presented Lord Armstrong with the Bessemer Medal, in recognition of the great services rendered by him to the manufacture of iron and steel, and especially of ordnance, and of his valuable researches on tempering and other matters.

The first and only paper read at this day's meeting was by Dr. W. Anderson, on

Tests for Steel Used in the Manufacture of Artillery.

He stated that specifications of gun steel exclude all definitions of chemical composition. Even chromium, aluminium, or nickel are not forbidden, but care is taken to ascertain their effects. The composition of steel for small arms is, however, restricted within certain limits, on account of hardening and uniformity. The effect of cooling either in cast or forged objects is to set up strains in them, and these are more pronounced when the cooling is rapid, as in the case of oil hardening. Tempering, however, reduces these strains and their effects, unless, indeed, cracks have been produced. The changes are by no means regular, as allotropic and chemical changes are affected by both temperature and pressure. It is necessary to test specimens under treatment similar to that which the whole mass undergoes, and for this purpose the specification now in force in Her Majesty's service lays down that the specimens, which are to be cut from the components of the guns in a carefully specified manner, are to be 1in. diameter by 4½in. long; they are to be heated to 1,425° Fahr., or a bright red, and quenched in oil of 65° Fahr. temperature, and left in the oil till cold. They are then to be turned down for a length of 2in. to a diameter of 0·533in., and tested by tearing asunder. Bending tests on specimens 4½in. long, and 0·75in. wide, and 0·375in. thick, cut to these dimensions after being oil hardened, are also prescribed.

Struck by the importance of the researches of Osmond, Roberts-Austen, and others, the author had proposed to the Institution of Mechanical Engineers that they should undertake a research into the behaviour of large masses of steel. The methods adopted he could not give, but it will very likely be possible to determine the quality and conditions from mere shavings turned off the mass. They prove that steel is ill treated within a range of 300° Fahr. Modifications in the specifications are to be introduced, which will provide for special methods of working the steel. The elastic limit is not defined in Her Majesty's service as it is in the specifications of all foreign Governments.

In the discussion which ensued, Professor Roberts-Austen described the means of measuring elevated temperatures when performing experiments on the behaviour of steel, especially when experimenting on allotropic modifications.

Mr. Hadfield pointed out the value of these means when working steel, as estimation of temperature by the eye was entirely a personal factor. He did not believe in oil tempering, if it were only on account of the cracks produced.

Mr. Carbutt thought that some of the surplus funds of the Institute might be applied to experimenting instead of allowing them to accumulate.

Other speakers briefly followed with remarks on oil tempering and on the recent investigations into the nature of steel and its alloys.

Mr. Watson Smith wished to know if vibration had any effect on the temper.

Mr. Snelus defended the value of chemical analysis, and wished especially to call attention to the danger of segregation of such elements as phosphorus in large masses of steel. He quoted experiments with zinc-iron alloys to show to what extent this might go. If 0·1 per cent. of phosphorus prevented them from making good cutlery steel from Cumberland hematite, there ought also to be danger in large masses. The interior of small test pieces would be more strained under the tests than the masses themselves.

In reply to the discussion, Dr. Anderson stated that oil hardening had not been given up, but that annealing was used, and the best methods to attain the best results were always employed if possible. He had hoped to have given them the new specifications, but, up to the present, they had not been published. As an example of the strains produced, oil hardened hoops opened or closed when cut, but remained neutral if they were first annealed. In guns there was no vibration to speak of, and so no effect would be produced. If they could tell the composition from the shavings, he thought they would overcome Mr. Snelus' objection on the score of unexpected segregation.

(*To be continued.*)

AN ELECTRIC PINNACE.

During last week we had an opportunity of inspecting an electric pinnace which is being tried on the Thames. This boat, which has been built by Messrs. Woodhouse & Rawson, United, Limited, for the Government, is intended for carrying troops between Chatham and Sheerness Dockyards. The "Electric," as she is called, is 48ft. 6in. long over all, by 8ft. 9in. beam, with an average draught of 2ft. 3in., and is intended to carry 40 fully equipped soldiers. Her speed on the measured mile is 8 knots per hour, and to meet cases of emergency she is fitted with two masts, two balance lug sails and a stay sail. The electric motor is capable of developing 5 h.p. The accumulators, which are stowed away under the seats, are capable of supplying current for a run of 10 hours' duration. During the short trial which we witnessed the boat appeared to fulfil all that was claimed for it. The ease and rapidity with which it was steered were specially noticeable. The cost of propulsion is estimated not to exceed that of steam vessels with similar carrying capacity.

RESEARCH COMMITTEE ON MARINE ENGINE TRIALS.*

REPORT UPON TRIALS OF THE S.S. "IONA."

Since their report of May, 1890, the Research Committee on Marine Engine Trials have had the opportunity of carrying out another trial, which will be found in some respects more complete than any of those they have made previously.

Steamer.—The steamer tested was the "Iona," owned by Messrs. Erskind & Woods, of West Hartlepool, to whom the Committee are greatly indebted for all the facilities they kindly afforded for the trial, and for the obliging arrangements they made for the comfort and convenience of all on board. The "Iona" is a fine example of a modern well-decked cargo schooner with economical engines. She was built in 1889 by Messrs. W. Gray & Co., of West Hartlepool, and engined by the Central Marine Engine Works of the same firm with triple-expansion engines on three cranks working a single screw. She is a vessel of 275·1ft. length, 37·8ft. breadth, and 19ft. depth. Her depth, moulded, is 21ft. 10in., and her coefficient of fineness is 0·765. She has a double bottom of cellular construction 230ft.

* Report prepared by Professor Alexander B. W. Kennedy, F.R.S., Chairman of the Committee, for the Institution of Mechanical Engineers, and read at the meeting of the Institution on the 31st ult.

Digitized by Google

long, and can carry 448 tons of water ballast. Her registered tonnage is—gross, 2,094 tons; under deck, 1,610 tons; and net, 1,348 tons; and she is classed at Lloyd's 100 A1 (special survey). Her draught in Tyne Docks before the trial started was 20ft. 7in. forward, and 20ft. 9in. aft, or 20ft. 8in. mean; but in salt water she rose ½in., as measured by hydrometer, so that the mean draught during the trial was 20ft. 7½in., corresponding to a displacement of 4,430 tons.

The "Iona" arrived at Middlesbrough from her voyage on 23rd June, 1890, and her engines were afterwards overhauled by their makers. She subsequently went north to the Tyne to take in a cargo of coal, and the trial was made during her outward voyage south. The steamer left Tyne Docks at 12·20 noon on 13th July, 1890, and crossed the bar about 1 o'clock, the weather being fine with a fresh breeze. The fires had been lit since 6 a.m. on the previous day, and, in order to get everything warmed up and the fires in normal condition, the trial itself was not started until 6·30 p.m. on 13th July, by which time the steamer was off Robin Hood Bay. The trial lasted for sixteen hours, ending at 10.30 a.m. on 14th July, when the steamer was off Yarmouth. The weather remained fine throughout, so that there was no difficulty in taking any of the usual observations.

Forced Draught Arrangement in the "Iona"

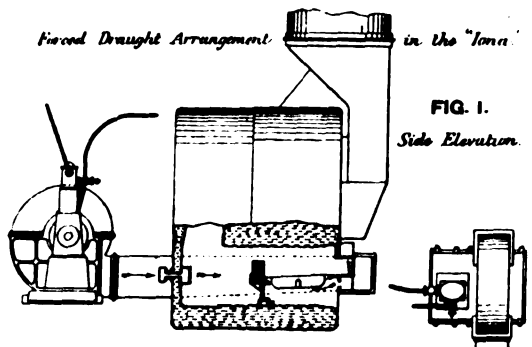

FIG. 1. *Side Elevation.*

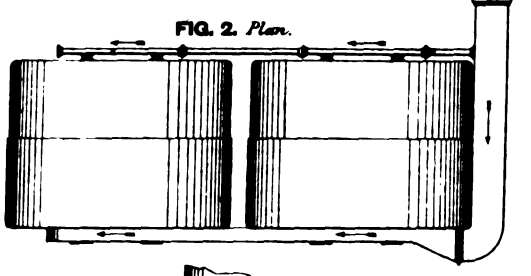

FIG. 2. *Plan.*

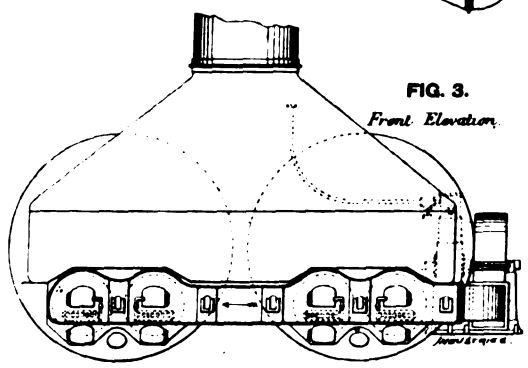

FIG. 3. *Front Elevation.*

The speed of the engines was not altered during the trial, nor was the valve gear touched or altered throughout the whole time. In addition to all the observations which had been taken on former trials, indicator diagrams were taken at intervals from the circulating and air pumps, from the first and second receivers, and from both ends of the condenser. The temperatures of the circulating water and discharge water were also noted, and the jacket-water, steam-pipe drain-water, and supplementary feed-water were each separately measured.

Engines.—The "Iona" is fitted with triple-expansion surface-condensing engines, the cylinders being placed in the order—intermediate, high, low, going from forward to aft. The cranks rotate in the sequence—high, intermediate, low. The diameters of the cylinders are 21·88in., 34·02in., and 56·95in., by gauges. The piston rods are all 5in. diameter. There are no tail rods. The stroke of all three cylinders is 39in. The high-pressure cylinder only is jacketed. Its jacket is supplied with steam from the boiler direct; under ordinary working conditions it is drained directly into the hot-well, but during the trial it was drained through a measuring tank. A drain pipe was taken from the steam pipe, and another from the high-pressure valve chest, and these were connected to another tank, so as to be also separately measured. The intermediate and low-pressure cylinders are not jacketed. The clearance volumes of the cylinders are given by the makers as 12·41, and 10·11, and 7·64 per cent. of the volumes swept through by their respective pistons. The high-pressure and low-pressure cylinders are provided with ordinary double-ported slide-valves, and the intermediate cylinder with a Trick slide valve. None of the slide valves are balanced. The valve gear is the ordinary link motion. There are two feed pumps, one circulating pump, one air pump, and two bilge pumps, all driven by levers from the cross-head of the low-pressure cylinder. The feed pumps are each 3in. diameter, single-acting; the circulating pump is 10in. diameter, double-acting; the air pump is 17in. diameter, single-acting; and the bilge pumps are 3½in. diameter, single-acting. The stroke of all six pumps is 26in. The surface condenser contains 1,360 square feet of tube surface, in 475 tubes of ⅝in. external diameter and 14ft. 7in. length between tube plates. The screw propeller is of cast-iron, having four blades, and is 14ft. 6in. diameter, with a mean pitch of 14ft. 6in. and a surface of 63 square feet.

Boilers.—Steam is supplied by two single-ended steel boilers with Purves' corrugated flues. The boilers are 13ft. 3in. in mean diameter and 10ft. long, with two furnaces each, or four furnaces in all. The total grate area was originally 52·5 square feet, each grate being 8ft. 9in. long, and 3ft. 6in. broad; but the fire-bars have since been shortened by the length of one brick to 3ft., so that at the time of the trial the total grate area was only 42 square feet. The total heating surface of the two boilers is 3,160 square feet, of which 2,590 square feet is tube surface. The total heating surface is therefore 75·2 times, and the tube surface 61·7 times the actual grate area. The ratios of total heating surface and tube surface to the original grate area are 60·2 and 49·3 respectively. There are in all 480 tubes, 3in. external diameter and 6ft. 10⅛in. long between plates. The internal diameter of the funnel is 6ft. 3in., and its total height is 51ft. 9in. above the level of the fire grates. A damper is placed in the funnel at a height of 17ft. 8in. above the level of the fire grates. The total cross-sectional area through the tubes is 18·3 square feet, and the area across the funnel is 30·7 square feet. The net volume of the boilers is 2,680 cubic feet. The boilers are worked under forced draught, on a plan designed by Mr. John R. Fothergill, the arrangement of which is shown in Figs. 1, 2, 3. A fan in the engine-room, driven by an engine which during the trial received steam from the donkey boiler, forces air into a trunk which extends across the front of the boiler. This air passes into the furnaces through gridiron valves placed just below the level of the fire-bars; each of these valves is made to close automatically by the lifting of the latch, whenever the corresponding furnace door is opened, thus preventing flame and gases from being blown out from the furnace into the stoke-hold. A smaller air trunk, branching off from the main trunk and provided with a deflecting valve, passes along the back of the boilers and admits a quantity of air through perforated plates into the combustion chamber, in the form of small streams which mix with the gases after they have passed the furnace bridge and have been deflected to the bottom of the combustion chamber by a plate hung at the back end of the furnace. The fan is 60in. diameter and 20in. broad, and is capable of supplying 14,000 cubic feet of air per minute at a pressure of 3¼in. water-gauge; it is driven direct by a Chandler's single-acting high-speed engine, with cylinder 8in. diameter and 7in. stroke, developing 2·1 indicated horse-power at a speed of 180 revolutions per minute, which was the mean speed during the trial. The fan engine is usually supplied with steam from the first receiver of the main engines; but throughout the trial, as already stated, steam was supplied to it from the donkey boiler. Water gauges connected to the casings and ashpits were read at intervals of half an hour, and the following are their mean readings:—

Position of Gauge.	Pressure.
On air trunk near fan	0·86in. of water.
On air trunk at back of boilers	0·34in. ,,
On ashpits, mean of four gauges	0·17in. ,,

Weights.—The total weight of the engines and boilers and all mountings, including water in condenser, pipes, and boilers, is about 202 tons, exclusive of shafting, tunnel bearings, and propeller. The following are the weights of the various parts of the machinery, boilers, and accessories, as given by the makers:—

Engines alone	64·92 tons
Shafting, tunnel bearings, and propeller	26·59 ,,
Engine-room auxiliaries, including donkeys, pipes, platforms, ladders, and gratings	12·16 ,,
Water in condenser, pipes, and pumps	1·71 ,,
Boilers alone	58·60 ,,
Boiler-room auxiliaries, including forced draught gear, smoke-box, uptake, funnel, furnace gear, mountings, stoke-hold floor, boiler chocks, and ties	28·49 ,,
Water in boilers	35·75 ,,
Total	228·22 tons

(To be continued.)

COCKBURN'S TYPE-WRITER FOR THE BLIND.

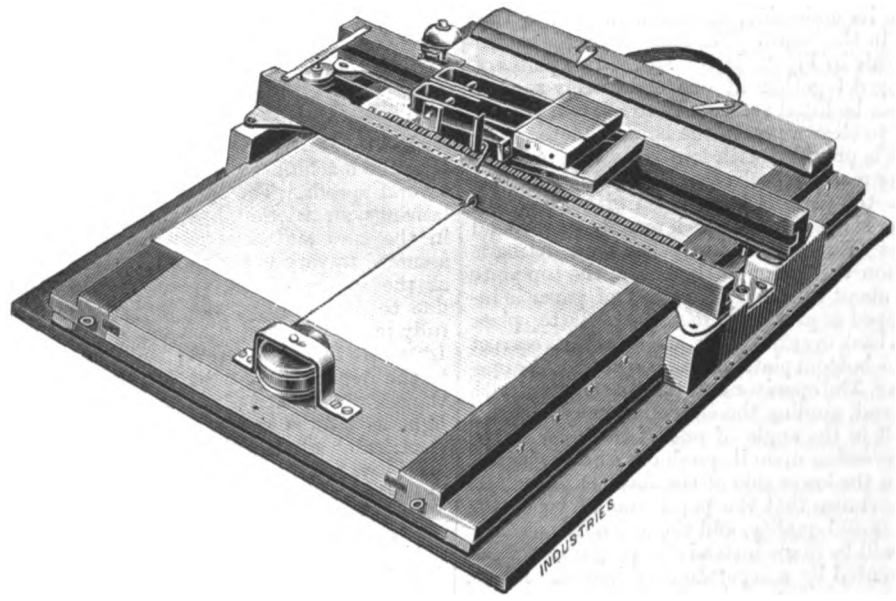

FIG. 1.

COCKBURN'S TYPE-WRITER FOR THE BLIND.

ON glancing at the above heading the question will arise in many minds, "How do the blind write?" It will therefore be of some interest to describe the method in common use for the purpose, and then to give a detailed description of the type-writing machine which is now superseding to a large extent the earlier apparatus.

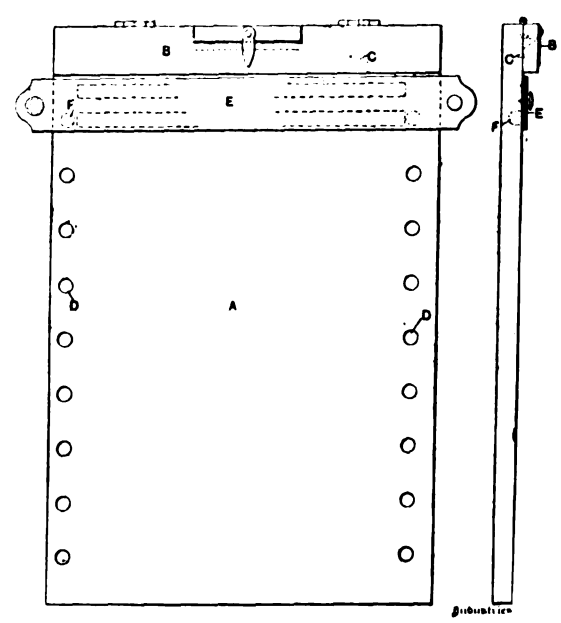

FIG. 2.

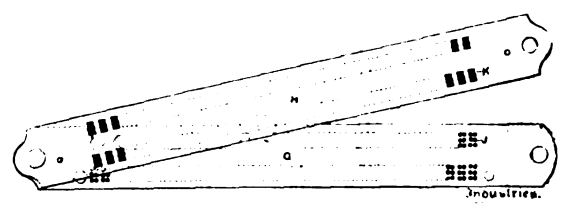

FIG. 3.

The ordinary apparatus is shown in Fig. 2 and consists of a board A provided with a hinged flap B at the top. The paper used by the blind for writing what is known as the "Braille" type is a specially prepared thick paper with a smooth face, and the size of the sheets is about the same as ordinary foolscap. Two pins C are fixed into the board itself under the hinged flap, and two others into the flap at a distance of about ⅜in. nearer

Digitized by Google

the top of the board. The sheet of paper is fixed in position by raising the flap, pressing the paper over the two pins on the board, and then closing the flap, so that there are then four holes in the sheet of paper, the use of which will be described later on. The sheet is now fixed firmly in position, and is ready to be written upon. Along each side of the board is a row of holes D equidistant from each other, and a brass fitting E stretches across the board from side to side and is provided with two pins F upon its underside, which can enter into two opposite holes in the board. The brass fitting is shown upon a larger scale in Fig. 3. It consists of two plates of sheet brass, hinged together at one end loosely so that the top plate can be lifted sufficiently to allow a hole at the other end to clear a pin in the bottom plate. The bottom plate G is provided with two rows of groups of holes J, or rather recesses, each recess being hemispherical in shape. The top plate H is provided with a series of holes K of the shape shown, which exactly correspond with the groups of recesses below. The brass fitting is placed in position at the top of the board, the top plate is then turned about its hinge, the sheet of paper is inserted and clamped as previously described; the top plate is then brought back over the paper, and retains its correct position over the bottom plate, and all is ready for the operation of writing. The operator now takes a small awl with a blunt point, and, guiding the end of the awl with his fingers, places it in the angle of one of the holes in the top plate, and, pressing upon it, produces a hemispherical projection upon the lower side of the sheet of paper. It is of great importance that the paper should be of the proper thickness and quality, and the awl not too sharp, or a puncture will be made instead of a projection. Each letter is represented by a separate combination of dots, which, of course, vary in position in a somewhat similar manner to the Morse code used in telegraphy. It will be readily seen that two lines of letters can be written with one setting of the cross-bar, after which it is necessary to move it into the next lower pair of holes upon the writing board. When the whole of one side of the paper has thus been filled, the sheet is turned over, and is now lowered the distance between the holes made by the pins upon the hinged flap and those upon the board itself, so that the rows of small projections now lie between those previously written upon the other side. The great objections to the use of the board, cross-bar, and awl are the extreme tediousness of the process, and also the fact that the use of the awl for any length of time produces cramp in the fingers.

The Cockburn type-writer does away with the use of an awl in the fingers, and substitutes a set of three keys similar to those used in ordinary type-writers. Fig. 1 represents a general view of the machine in working order. It will be seen that the board with the hinged flap is present as in the old apparatus, and the same method of fixing the paper is employed. Instead of the cross-bar composed of two brass plates a carriage is here used, which can slide from top to bottom of the board; a cord is attached to the slide and passes round a drum in which a spring is coiled. There is thus a constant tendency for the slide to move towards the drum. This is prevented by a spring catch, which strikes against pins, the pins acting for the same purpose as the side rows of holes on the simple board. After writing each line the spring is released, and the slide passes down sufficiently far to enable another line to be written. The slide itself carries a bar with recesses or holes as in the simple form. Upon the slide is fixed a traveller, to which is attached a cord, which passes round a drum containing a coiled spring; the traveller has thus a tendency to cross the board. It carries three keys, which act upon punches in such a way that the punches cause the paper to enter the recesses in the cross-bar and produce the projections. Supposing the traveller to be at one edge of the board; then one, two, or three punches will be depressed, as the case may be. A fourth key is then pressed, which projects beyond the other three, and this releases a pawl from the tooth of a rack fixed to the cross-slide, and allows the traveller to advance the distance between the two rows of three recesses. The punches may then be again depressed, and next time the fourth key allows the pawl to pass over a wider space, in order to separate the groups forming letters. A bell is placed on the cross-slide which gives notice when the traveller has reached the end of its course. The traveller is then brought back, the cross-slide lowered, and a new line can be written. At the edge of the board are placed marks which enable the operator to tell at what distance from the top of the paper he is writing, and along the edge of the cross-slide are pins by which he can tell how far across the paper he has written.

The machine is a very ingenious contrivance, and appears to have received the approval of all who have used it. A considerable number of them are now in use. Sample machines are on view at the offices of Messrs. Cockburn, Phillips, & Montgomery, 2, Princes Mansions, Victoria Street, S.W.

FOUCAULT CURRENTS IN DYNAMOS.

By J. Swinburne.

The question of the loss in dynamos by Foucault currents in the armature cores and windings has been brought prominently forward lately. Mr. Kapp and Mr. Housman published accounts of a method of estimating the losses in a recent number of the *Electrician*. Moreover, Mr. Kapp explained the method at the Institution of Civil Engineers, and Mr. Housman at the Institution of Electrical Engineers, and the importance of the subject warrants its being brought forward so prominently. The method of estimating the loss by Foucault currents described by Messrs. Kapp and Housman consists of running the machine as a motor with no load at two or several speeds. The losses are due to friction in the bearings, air friction, hysteresis, and Foucault currents in the core and armature bars. The first three are assumed to vary as the speed, and the Foucault currents as the square of the speed. This method is, however, due to Mr. Mordey, who worked the subject out very fully in his paper on "Alternate Current Working" in 1889. He did not, however, supply the power electrically to the dynamo, but used a transmission dynamometer, though the method of testing dynamos by running them light as motors was well known. Supplying the power electrically admits of its being measured with greater accuracy, but does not allow the Foucault currents in the core to be determined before the armature is wound.

The method has, however, one very serious objection—viz., that the loss by Foucault currents at full load is very much greater than at no load, at least in a large machine, and this makes the method inaccurate. The loss by Foucault currents in the discs is increased considerably by the distortion of the field due to the armature current, and the losses by Foucault currents in the conductors are increased greatly by the same cause. The method may thus under-estimate the losses very considerably—that is to say, the losses may be double those determined in such a way. This is discussed in my paper on "Armature Reactions" in 1890, so I need not go into it farther here.

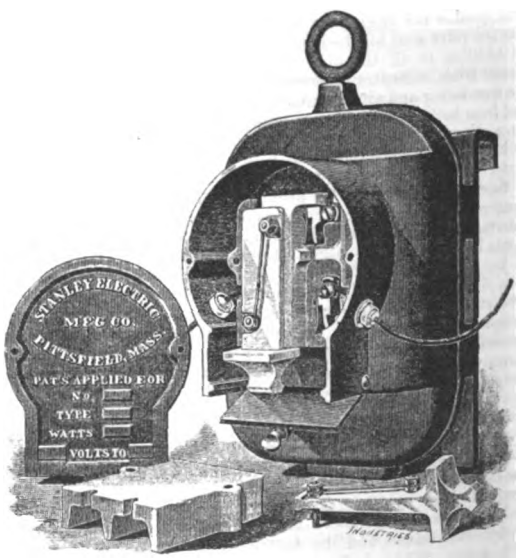
I tried a number of experiments on the stray power in 1886. Various dynamos were run as loadless motors, but the results were all vitiated by variations of the friction. The machines were, however, comparatively small, and the friction may have been large in proportion to the hysteresis and Foucault currents. I do not mean to imply that I forestalled Mr. Mordey in 1886; I was merely attempting to separate the electrical and mechanical losses. The assumption that the loss by friction varies as the speed is gratuitous, and Messrs. Kapp and Housman are really trying to determine three unknown quantities from two equations. Mr. Mordey can, however, find the friction losses at various loads, and can thus apportion the no load losses accurately. I tried another method of finding the loss by hysteresis and Foucault currents in the core. The armature, before being put in the machine, had one wire disconnected from the commutator, so that the circuit was open. The armature was then treated as a choking coil, and the power measured when an alternating pressure was applied. There was no wattmeter available, so a current dynamometer was employed. The fixed coil was put in series with the armature, and the moving coil, which had only one turn, was put in series with a non-inductive resistance. The dynamometer thus became an accurate but wasteful wattmeter. By using more than one frequency, the Foucault current and hysteresis losses can be separated according to Mr. Mordey's equation.

Alternating currents also supply a most convenient method of testing armature insulations during the progress of manufacture. Before the last connections are made to the commutator, several sections are included between the terminals of an alternating machine. The armature then acts as a transformer, transforming up, and testing its own insulation. This method was introduced at Messrs. Crompton's works about four years ago, and has, I believe, been used ever since. It may be made too severe, and any armature can be broken down by including few enough turns between the terminals of the alternating dynamo.

The loss by Foucault currents in a disc which is uniformly magnetised can be calculated if the specific resistance of the iron is known. Discs are sensibly uniformly magnetised in a transformer, and I have elsewhere* given the formula—

$$P = 2{\cdot}6\, B^2 n^2 t^2 10^{-16} R^{-1},$$

where P is the power wasted per c.c. of iron, B is the induction, n the frequency or revolutions per second of a two-pole dynamo, t the thickness of each disc in centimetres, and R the specific resistance of the iron in ohm centimetres. It will be noticed that the diameters, internal and external, do not appear in the equation, so that the loss per cubic inch does not depend on the size of the machine. To give a concrete example, we may take a two-pole dynamo with a 20in. by 20in. armature with a 14in. hole, and 600 revolutions per minute. If the armature induction is 13,000, the loss by hysteresis comes out 450 watts, while, taking the specific resistance of iron at 10 microhm centimetres, the loss by Foucault currents is 370 watts if the discs are $\frac{1}{20}$in. thick. The induction does not vary in a dynamo in the same way as in a transformer, so this is too low an estimate. It will be nearer the truth to take it at 450 watts also. In a small machine, which is run at 1,200 revolutions or so, the loss by Foucault currents may easily be four times that by hysteresis with the thickness of discs commonly employed by makers. It is here assumed that the discs are insulated from one another. There is no difficulty in separating them well enough to avoid any Foucault currents due to contacts.



Foucault currents in bars can also be calculated roughly, but only roughly. As large bars are seldom used there is no need to go into the methods of calculating. Twisted conductors get over the difficulty if the various component wires are not in good enough electrical contact to allow the Foucault currents to flow. The only way to determine these losses is to test the machines at full load by some of the modifications of Hopkinson's method. There are also serious losses by Foucault currents in Gramme machines, which may not appear at all at no load.

The losses by Foucault currents in the conductors are often very serious in alternating current machines. As the cross-induction is generally small in such machines, Mr. Mordey's method will give accurate results. The superposition of the main current does not increase the loss. For instance, if there were 100 watts lost in a main by a current already flowing, and a second current is superposed, which by itself would produce a loss of 100 watts, the two together would waste 400 watts, not 200 watts. In a dynamo, however, if the Foucault currents waste 100 watts in the conductors, and the armature loss by C^2R is, say, 200 watts, the total waste is 300, not 583 watts. It is, perhaps, unnecessary to give the explanation of this here.

* B.A. Paper on Transformer Design, 1889.

THE "STANLEY" TRANSFORMER.

The accompanying illustration shows the details of arrangement of the latest type of "Stanley" transformer. As these transformers are manufactured by the Stanley Electric Manufacturing Company, of Pittsfield, Mass., U.S.A., we may surmise that Mr. Stanley has severed his connection with the Westinghouse Company, and that he is putting forward apparatus of his own design independently.

These transformers are arranged without any secondary fuses, while the primary fuses are longer than usual in America. The secondary fuses are put in the circuits elsewhere. The whole practice relating to fuses is different in England and America, and it is time this very important matter was thoroughly ventilated and discussed. The average American transformer has half an inch or so of primary fuse on each terminal, while in this country primary fuses are separate structures in cumbrous porcelain or stoneware cases. These transformers are made in sizes for 10, 20, 30, 40, and 100 lamps.

SOME EFFECTS OF ALTERNATING CURRENT FLOW.*

The simple cases of circuits with resistance and self-induction and capacity in series are first examined, and the phenomena of electrical resource are fully investigated. Warnings against using step-up transformers for testing cable insulations are given, with the author's reasons. He then discusses the effect of the capacity of the Ferranti mains upon the electromotive force at various parts of the circuits, and describes some experiments made at Deptford. These show that there is no foundation for the statement that the pressure is ever higher at London than at Deptford.

The condenser effect, and in particular the alteration of the change ratio of a transformer which takes place when its secondary circuit is connected to a conductor system having a certain capacity in relation to the inductance of that secondary circuit, is found to operate in many curious ways in the practical use of such combinations. For instance, if a pair of alternators separately excited are working in parallel on an omnibus main leading to a conductor system of no sensible capacity, then we know very well that if the dynamos are synchronised, and contributing equally to the outgoing current, the method adopted to take one dynamo out of circuit would be to lower its exciting current, and when its outgoing current fell to zero to sever its connection with the omnibus main. If, however, the alternators are working through step-up transformers, and into a conductor system consisting of concentric cable, it is found by experience that the exciting current of the dynamo to be taken out must be raised, and not lowered, in order to bring it into a condition in which it can be cut off from the omnibus main without dangerous sparking at the switch; and, conversely, in putting it into parallel the incoming alternator has to be excited to a lower electromotive force than is necessary to maintain the standard P.D. at the terminals of the step-up transformer before putting it into connection with the omnibus main. This is obviously due to the fact that the change ratio of the step-up transformer is altered by the very act of putting it into connection with the conductor system, and hence the excitation of the alternator at the moment of making or breaking connection with the main must be such as will bring the P.D. of the free secondary terminals of the step-up transformer to a value equal to the P.D. of the two points on the conductor having capacity to which they are about to be connected, or from which they have just been severed; and when the connection of the alternator is made, the excitation can be altered to divide the load on the machines properly. This, of course, would not be the case if high-tension alternators of very small inductance were set to work in parallel on such a concentric conductor system. In this case the condenser effect is practically nothing, and the behaviour of the machines on going into or out of parallel would present nothing unusual.

In the cases briefly discussed above, the cables, whether concentric or simple, have been found to act as single condensers substituted for them would act; and in the experiments described no progressive rise of pressure from one end to the other of a cable possessing capacity was found to exist.

It is, however, quite possible for self-induction, resistance, and capacity to be so combined together in one conductor that the action of an impressed periodic electromotive force at one end will create a progressive rise of mean pressure along the cable when the far end is insulated.

* Abstract of a paper read by Dr. J. A. Fleming before the Institution of Electrical Engineers on the 7th inst., and fully entitled "On Some Effects of Alternating Current Flow in Circuits having Capacity and Self-Induction."

THE MANUFACTURE OF SOAP.

By W. Lawrence Gadd, F.I.C., F.C.S.

VII.

(*Continued from page 427.*)

Mottled Soap.—Household blue and grey mottled soaps are commonly made from the oils mentioned above, or from tallow, cocoanut or palmnut oil, and lightest coloured rosin. In each case the process of manufacture is practically the same as described for yellow soap, so far as, and including, the operation of boiling on strength. After settling, the half-spent lye is drawn off as completely as possible, and the soap is then closed or fitted with a solution of sodium silicate. Crystals of sodium carbonate are also often added, and, when the original fats are not of sufficiently good colour, a solution of bleaching powder is sometimes used to whiten the soap. As little, however, of this substance should be used as possible, because its addition to the soap gives rise to the formation of a calcium salt of the fatty acids, which is insoluble in water, and is useless for washing purposes. The soap is then finished by boiling for some time with closed steam, or by fire, to evaporate excess of water, until a sample taken out of the pan and cooled sets with the required firmness, and contains only the desired percentage of water.

The colouring matter, or mottling material, which is usually ultramarine for blue mottled soap, and manganese dioxide or plumbago for grey, is then stirred up with a little hot silicate solution, and added to the mass, with which it is thoroughly incorporated by boiling. If properly made and finished, the soap has now a thick, flaky appearance, and, if ultramarine has been added, has a uniform, dark, bluish-grey colour. It is not advisable to add the colour, especially ultramarine, until the last moment, and the soap should then be ladled out, or otherwise withdrawn from the pan, and placed in the frames with as little delay as possible.

The separation of the colour into small spots and patches, to form the mottling, requires a certain amount of time, during which the soap must be kept in a fluid condition; hence the frames used for mottled soaps must be such as will retain the heat for a considerable time, and only allow the soap to cool slowly.

These frames are of two kinds, wooden and iron. The former consists of a number of wooden sections, lined inside with zinc (see Fig. 13), one of which is placed on a frame bottom or base, and others fitted into sockets, one upon the other, to form a soap frame of almost any desired height. When a sufficient height is attained the separate parts are firmly clamped together by long iron rods, attached to the frame bottom

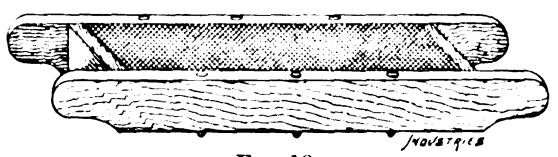

Fig. 13.

and connected with cross-heads placed across the top section at each end, pressure being applied by a screw. These frames, being of wood, allow the heat to dissipate only slowly, and, although somewhat cumbersome, they are excellent for mottled soaps. The iron frames are similar to the ordinary ones, but the bottoms are double or jacketed, and heated by steam, so as to retain the heat of the soap and allow time for the colour to aggregate into patches and so form the mottle. When solid, the soap is cut into slabs and bars in the manner already described.

The above description refers to the manufacture of mottled soaps of the better class, containing 45 per cent. to 50 per cent., or more, of fatty anhydrides; but there are also cheap mottled soaps in the market, which are made in a few hours, instead of days, from cocoanut and palm-kernel oils, on the principle of marine soap. This soap differs from those already mentioned in that it contains the whole of the glycerine formed during the process of saponification, no lye being separated or removed from the pan. It is generally made in a pan provided with open steam coils, and also jacketed for heating by closed steam, or else capable of being heated by fire. The oil is saponified by relatively strong alkali, using open steam for the boiling. Comparatively large quantities of water, silicate of soda, soda ash, and common salt are then added, and the soap finished by boiling with closed steam or by fire in the same way as ordinary mottled soaps. The whole contents of the pan are then run into ordinary iron frames to be mottled. The thick fob of scum or froth, which forms on the surface of the soap in each frame, is skimmed off, and the colour crutched in by hand, after which the frames are covered with sacks and the soap allowed to cool.

The colour should be added while the soap is hot—the hotter the better—if a good strike and bright colour be desired; but as the soap is extremely thin and deficient in body, there is considerable risk of the mottling material sinking entirely to the bottom of the frame if the crutch be withdrawn and the soap left at rest too soon; while, on the other hand, prolonged crutching is certain to prevent the mottling from taking place at all. In the one case, the bulk of the soap turns out perfectly white, all the colour being contained in the bottom two or three slabs; in the other case, it has either one uniform tint of blue or grey, or else the colour is distributed evenly throughout the mass, in the form of minute points or dots. Some experience is therefore necessary in deciding when to leave this class of soap to mottle, the best way being to stop the crutching at a point determined by observations of the temperature and density of the liquid soap. Mottled soap, made in this way, usually contains more than half its weight of water, and from 20 per cent. to 30 per cent. of fatty anhydrides. It is very liable, on exposure to air, to become crusted all over with fine needle-shaped crystals of sodium carbonate, from the large quantity of soda ash contained in it.

The following analysis gives the composition of a sample of this class of soap, from which it will be seen that it contains comparatively little real soap, although the presence of silicate and carbonate of soda, and even of caustic soda, in this soap, which is mainly used for scouring purposes, cannot be considered altogether as a disadvantage:—

Analysis of Low-priced Blue Mottled Soap.

	Per Cent.
*Fatty anhydrides	18·98
Soda, existing as soap	2·79
" " silicate	·09
Silica	·22
Free caustic soda	none
Sodium carbonate	3·92
Sodium chloride	4·79
Ultramarine	·10
Water and glycerine	69·11
	100·00

* Equivalent to 19·57 per cent. fatty acids, derived from cocoanut oil.

(*To be continued.*)

SOCIETY OF CHEMICAL INDUSTRY.

LONDON SECTION.

The last meeting of this section was held on the 4th inst. The title of the paper by Messrs. Archbutt and Deeley, as first announced, was somewhat modified at the time of reading the paper, the new designation being "The Treatment of Hard Water," and the subject really being the description of a series of experiments made by the authors on the softening of the feed-water for locomotives at the Midland Railway Company's works at Derby. After an historical sketch of the process of water softening, in which it was suggested that the ordinary use of lime for this purpose should be ascribed to Henry rather than Clark, reserving for the latter the credit of introducing the soap test, the qualities of an ideal process were enumerated. Such a process must be effected by the use of the simplest and cheapest chemicals and plant, must cost little in labour, and be suitable for all kinds of water. Though not claiming these advantages in an absolute sense for their process, the authors considered that they had made a perceptible advance towards attaining them.

The experimental plant which they had employed consisted of a tank holding 20,000 gallons, into which the water to be treated was run, and a smaller tank, in which the reagents used were brought into solution or suspension by boiling. The concentrated purifying liquor was allowed to flow into a well in the large tank, at the bottom of which was a steam injector, whose action mingled it with the rest of the contents of the tank. The sludge produced by a previous operation was permitted to remain at the bottom of the large tank during this process, and become stirred up with the new volume of water being treated. Air was also blown in to complete the admixture of the already precipitated lime and magnesium salts with those in the act of precipitation, and it was found that the effect of so doing was to clarify the water at a much more rapid rate than was possible by ordinary subsidence. The reagents used were simply lime, soda ash, and sulphate of alumina, the last named being added only to the extent of about 1 grain per 1,000 gallons. Ferrous sulphate has been lately substituted for the sulphate of alumina with success. Settlement was so rapid that the nearly clear liquid, containing only about 1 grain per gallon of suspended matter (less than the water before treatment), could be drawn off in about an hour, and even this short period could be reduced, if necessary, by the use of a specially constructed pipe. The mixing appliances were cheap, efficient, and manageable; the labour was light, involving little beyond opening and shutting a few valves; and its cost did not exceed one farthing per 1,000 gallons.

No great novelty was claimed for the process, its efficiency depending rather on the careful adoption of the best method of working from a mechanical point of view than on any special chemical conditions. The authors particularly insisted on the advantage of abandoning the use of caustic soda, which was comparatively expensive, and in careless hands gave rise to much mischief. A glaring instance of the waste that frequently resulted from its abuse was afforded by a water which had come under their observation, and which, after softening, contained 29 grains per gallon of sodium carbonate and 4 grains per gallon of caustic soda.

The precipitated lime and magnesia salts in their process were easily removed from time to time. but a portion was always left to aid in clarifying the next batch. The water thus softened had been in use for a battery of four old locomotive boilers which supplied steam for one of the shops at Derby. One difficulty had presented itself: it was found that the valves, feed-pipes, and injectors became coated with a thick soft deposit which gave serious trouble. It was proved to be due to the tendency of the purified water to deposit a further small quantity of solid matter on heating. A remedy was devised, which consisted in carbonating the clear effluent by means of the gases from a coke stove. With this precaution not only was there no deposit, but that already formed was removed. The sulphur in the coke was of no moment, the alkalinity of the water being more than ample to neutralise the trace of sulphuric acid that might find its way in from this source.

The efficiency of the process appears evident from the following analyses:—

Digitized by Google

	Before Treatment. Grains per Gall.		After Treatment. Grains per Gall.
Calcium carbonate	9·74	...	2·25
Magnesium carbonate...	2·45	...	2·18
Sodium carbonate	—	...	0·85
Calcium sulphate	5·64	...	—
Magnesium sulphate ...	1·34	...	—
Sodium sulphate.....	3·41	...	11·33
Sodium chloride	2·81	...	3·38
Silica.....	0·34	...	0·48
	25·74		20·47

A considerable organic purification was also effected.

In the discussion which followed Mr. W. Thorp doubted whether the well in the mixing tank was necessary, and feared that the use of a blast of air as an agitator might be somewhat costly. It was often forgotten that the work necessary to drive a given volume of air through water at a given depth was precisely equal to that required to raise the same volume of water to a corresponding height. Mr. Harland objected to the use of a large tank, on the ground that in many cases room for it was not available. Mr. B. E. R. Newlands spoke of the difficulties that were often met with in working a process of this description, due to the constantly varying composition of the water to be treated, and congratulated the authors on the measure of success they had achieved.

Mr. Archbutt, in reply, said that the well had been found of service, and was, therefore, retained; he did not think the cost of admixture was high. With regard to the tank room necessary, it must be remembered that, owing to the rapid subsidence, large quantities of water could be handled in a short time, even when a very moderate area was available.

A note by Mr. A. H. Allen, serving as an appendix to his recent paper on the "Chemistry of Whisky and Allied Products," was then read, the chief point of interest being a statement to the effect that cork and wood shavings exercised a considerable selective action on whisky, removing fusel oil and similar impurities. After a brief discussion the meeting adjourned.

Notes.

ANHYDROUS SULPHURIC ACID.

Ordinary vitriol, however strong, never contains more than about 98 per cent. of real sulphuric acid. At Teutelew's Chemical Works in St. Petersburg the well known plan of freezing the acid, and thus getting crystals of the really anhydrous acid, is in successful operation. Using acid of 96–97 per cent. strength, crystallisation is effected by cooling to $-10°$ C., and throwing in a crystal of H_2SO_4 to start solidification. The first crop of crystals is not quite anhydrous, but by repeating the process pure crystallised H_2SO_4 is obtained. The crystals necessary to start crystallisation can be obtained by cooling a specially strong acid made by mixing vitriol with Nordhausen acid.

H.M.S. "VULCAN."

The progressive trials of H.M.S. "Vulcan," referred to in our last issue, were commenced on the 30th ult., but came to an untimely end. The ship had done two runs each at 10 and 12 knots, and four at 14 knots; she then tried 16 knots, but, on the third run, the now unfortunately familiar occurrence took place—two of the boilers commenced to leak in the tubes, one very badly, and flames issued from one furnace door burning one man, but not, it is said, very severely. The reasons for the accident have not yet been determined, and the case is stranger than usual, for here we have a ship, after steaming continuously at 18¼ knots for eight hours, breaking down after a short run at a much lower speed. Messrs. Humphreys & Tennant and the Engineer-in-Chief of the Navy have been examining into the matter, but with what result is not, as we have said, yet known.

RAILWAY SIGNALLING.

At a recent meeting of the Cleveland Institution of Engineers, Mr. W. J. Cudworth read a paper on "Railway Signalling." The author stated that the semaphore began to be generally adopted in the year 1851, and was then a new invention and the subject of a patent. In a report of that date it was stated that the reconstruction of twenty signals on that system would cost about £200. At present there are 212 levers in the three signal cabins in connection with Darlington Station alone, and the cost of signals, cabins, interlocking, and connections would probably be not far, if at all, short of £7,000. The author stated that in the Middlesbrough district the smoke from the iron-works often causes trouble, and makes electric repeaters necessary when they would not be otherwise required. To show how closely the junctions often were placed to each other, the author gave the distances between the following signalling cabins between Middlesbrough and South Bank:—Sussex Street to Middlesbrough East, 325 yards; Middlesbrough East to Guisborough Junction, 383 yards; Guisborough Junction to Whitehouse Crossing, 1,146 yards; Whitehouse Crossing to Cargo Fleet, 873 yards; Cargo Fleet to Tees Tilery, 1,285 yards; Tees Tilery to Eston West, 903 yards. The interlocking frame in use on the central division of the North-Eastern Railway is known as Stevens' mitre lock. In the whole North-Eastern system there are 387 junctions of passenger lines with other passenger lines, 259 junctions with goods lines, 1,901 junctions with sidings, and 788 cross-overs, and a total of 3,335 connections with passenger lines, whilst in Great Britain and Ireland there are altogether 39,397 of such connections, and nearly the whole of these are carefully signalled at heavy expenditure.

CROSS TALK IN TELEPHONES.

Mr. J. J. Carty has recently read a paper before the American Institute of Electrical Engineers, in which he again urges his view that telephone disturbances are due to static and not to magnetic induction. Mr. Carty does not merely bring forward a theory, but he supports his case by experiment. On the face of it anyone would say that the disturbances due to static induction must be infinitely less than those due to magnetic induction. In a given case the disturbance due to the two inductions can be calculated, but Mr. Carty gives no information. The higher the pressure and the smaller the current used in the telephone circuit, the greater will be the relative effect of static induction, but it seems incredible that in ordinary practice the static could possibly be greater than the magnetic effect.

HARBOUR WORKS AT HAVRE.

The works about the basins, the harbour, and the roadstead, either finished, commenced, or projected during 1890, are the construction of two new sheds for goods on the quays, making the total number 18, with a length of 6,652ft., and a covered space of about 66,000 square yards. The number of hydraulic cranes is 17, with a lifting power of 1¼ tons, a floating one of the same force, and two stationary ones of 3 tons. A floating one of 10 tons will shortly be completed. The enclosure of the Bassin Bellot and of a portion of the Bassin de l'Eure is also projected. Notwithstanding the increased accommodation afforded by the Bassin Bellot, there have been occasions during the past year when the quay accommodation has been found insufficient for the vessels wanting berths, and, as about 540 yards of the quays of the eastern portion of the basin are now taken up by petroleum ships, it is proposed to make a dock for this traffic further on, at a cost of £46,000, half of which will be paid by the State and half by the Chamber of Commerce, which will raise a loan of £23,000 for the purpose. The Chamber of Commerce had already voted a sum of £20,000 towards the purchase of a more powerful dredger, in place of the one which was sunk at the end of last year.

TELEGRAPH EXTENSION UNDER DIFFICULTIES.

The *Pekin Gazette* recently contained a statement from the Viceroy of Yünnan, reporting that the line of telegraph communication in Yünnan has been extended to Momein, on the borders of Burmah. The statement explains that the project of constructing a line from Yünnan city to Momein for the purpose of establishing communication with the south-western frontier was set on foot immediately after the telegraph system of Yünnan was connected with that of Szechuan, Kueichow, and Canton. The task of making the preliminary surveys was intrusted to a Chinese official, aided by a foreign artisan. Part of the materials were procured from the surplus stock in Szechuan and the remainder had to be conveyed from Shanghai by way of Luchou in Szechuan under the care of officers specially deputed for the purpose. On reaching Yünnan the materials were divided into portions and stored at various places on the way between Yünnan Fu and Momein. The task of surveying the route and procuring the supply of poles occupied from March, 1888, to February 23rd, 1889. The construction of the line was commenced on the latter date and was completed on the 30th of May following. The distance from Yünnan Fu to Momein is 1,600 li (530 miles), and the route lies through a mountainous and densely-wooded country, where frequently no trace of habitation occurs for over a hundred li. The work was carried on by day under a blazing sun, which caused intense thirst, while by night the men were obliged to camp out in the open and were continually disturbed by the howling of wolves and tigers. The Mekong, the Salween, and the Shweilei rivers had all to be crossed in fever-stricken localities. The passage of the Salween, in particular, is attended with horror. Its waters are muddy and turbulent, and so deadly that the feet of men and hoofs of horses rot and drop off from contact with them. The officers and men of the expedition crossed the river on rafts constructed of coils of wire, and only reached the opposite bank after a very hard struggle. The season being summer, the malaria was at its worst, and no fewer than ten members of the party succumbed to its effects during the three days occupied in carrying the telegraph line across the river. The difficulties connected with the construction of this extension line have been far greater than any experienced in first introducing the telegraph system into Yünnan, and it is asked that the officers engaged on the work may receive reward on the same scale as is accorded in practice for the safe transmission of urgent messages from the field of battle.

THE ANALYSIS OF CHROME IRON.

Since chrome iron cannot usually be attacked by acids including aqua regia, nor brought into a soluble form by fusion with carbonate and potassium chlorate, and since the method of Fresenius and Hintz (viz., treatment in a current of heated chlorine gas), although accurate, is difficult and tedious, the following method may be recommended, says *Stahl und Eisen*, providing that, as is usually the case, only chromium, iron, silicon, and manganese are to be determined. One gramme of chrome iron is mixed with 8–10 grammes of dry bisulphate and fused for about an hour in a platinum crucible; it is then removed from the flame, 2–3 grammes of bisulphate of potassium added, and the whole again heated for a few minutes to convert the basic sulphates, which have been formed by the long-continued fusion, and which are difficult to decompose into neutral salts. The fused mass is extracted with boiling water and hydrochloric acid in a porcelain basin, and the silica filtered off, dried, and weighed. If any chromium oxide is included in this, the fusion must be repeated. Evaporation to dryness is not necessary. One quarter of the filtrate is neutralised, as far as possible, with caustic potash or soda and 0·5 gramme of magnesia suspended in water added; the liquid is kept hot until the precipitate has completely settled, and the latter is then filtered off, washed, and ignited, after which it is rubbed to a fine powder and fused in a platinum crucible with potassium chlorate and carbonate fusion mixture. The chromate is extracted from the fused mass by hot water, and, after reduction with sulphurous acid, precipitated by ammonia. The manganese is determined by the usual calorimetic method in another portion—one-tenth of the original filtrate. Before doing this, however, the chromium must be removed by precipitating the sulphuric acid with barium chloride, neutralising with sodium carbonate, and precipitating with barium carbonate. The iron is titrated with potassium permanganate, the colour of the chromium being found not to interfere, provided that the solution be sufficiently dilute.

THE COTTON INDUSTRY.

Though the position of cotton spinning in Lancashire is bad so far as regards American cotton, the employers have not been able to agree upon organising a general stoppage of the spindles during the whole of the approaching Whit week. An effort has been made in this direction, but it has failed. Weft spinning, as distinct from twist spinning, is unremunerative. Not only is the margin very poor, but stocks of moderate dimensions are found to be accumulating in first hands. Coptwist is a trifle better, for spinners can see a little profit. During the past few days the market has stiffened somewhat, and rather more cloth business has been done. The Oldham Cotton Buying Company has had a satisfactory quarter. The company has bought for spinners 27,251 bales in three months. This is a moderate proportion of the cotton bought by spinners as a body. The money represented by the business is £520,000. The company is now well established, and efforts will shortly be made to open out connections in the United States for a business with planters.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

20th April, 1891.

6752. White, W. ..... Stop valves.
6757. Oddy, F. ..... Caps for cap spinning and twisting frames.
6765. Brookes, A. G. ..... Spooling machines (*Foster*).
6769. Ward & Lancashire ... Knitting machines.
6779. Kerkes, P..... Signalling excessive fall of water level in steam boilers.
6792. Lee, J. W. ..... Apparatus for facilitating the stopping and starting of tramway vehicles.
6795. Coward, W. H. ..... Pulverising mill.
6801. Harris, A. ..... Filters for purifying the feed water of steam boilers.
6803. Mudd & Airey ..... Stuffing-boxes and glands and metallic packing.
6804. Garnier, T. R. ..... Ore concentrators.
6806. Boult, A. J. ..... Automatic water supply regulators for steam boilers (*Henry*).
6809. Barcroft, H. ..... Apparatus for propelling and steering boats.

21st April, 1891.

6812. Lobnitz, H. C. ..... Endless chains and buckets of dredging machinery.
6815. Barr, J. ..... Self-closing taps.
6817. Weir & Weir..... Apparatus for condensing steam and for obtaining fresh water from saline or other waters.
6821. Pye, R. ..... Appliance for moistening, heating, cooling, and ventilating factories.
6826. Eastwood, H..... Smoke burning bridge and fuel economiser.
6830. Smith, Smith, & Eastwood..... Apparatus for controlling the admission of steam or other elastic fluid to the cylinders of steam or other engines.
6840. Gedge, W. E. ..... Repeating guns (*The Ostrander Repeating Gun Company*).
6841. Rung, G. A..... Apparatus for sounding or measuring the depth of water.
6848. Wardale, J. D. ..... Fluid pressure engines for operating capstans.
6858. Fairfax, J. S..... Brake piston indicator for railway rolling stock (*Brown*).
6859. Altmann & Gray ..... Rail gauge adjuster with self-indicating index.
6860. Purdon, Walters, & Woodcock ..... Roller and ball bearings.
6873. McKee, R. ..... Drills for boring wells.
6876. Taylor, J. D..... Railroad signalling apparatus.
6877. Anderson, W. N. ..... Doors for lifts and means for operating the same.
6879. Lake, H. H..... Knitting machines (*Gormley*).
6881. Walcott, J. E. ..... Apparatus for covering electric wires.
6889. Newton, H. E. ..... Grease trap or intercepter (*Griffiths*).
6892. Hatfield, S. P. ..... Ordnance batteries.
6893. Adams, J. A. ..... Spring motors.
6894. Lake, H. H..... Apparatus for preventing incrustation in steam boilers (*The Nye Boiler Cleaner Company*).
6895. Ockenden, W. ..... Construction of boiler furnaces or flues.
6897. Hanna, H. B. ..... Steering of ships.
6898. Pyke, J. G. ..... Drilling machines.
6902. Edwards, E. ..... Fire engines (*Kieslich*).

22nd April, 1891.

6907. Mackett, A. E. ..... Mitre cutting machines.
6925. Garrett & Gozzard..... Automatic ball valves.
6931. Reichelt, Rattrit, Specht, & Marsh..... Spring motors.
6932. Harling, J. ..... Hydraulic engine.
6935. Gill, J. ..... Signalling on railways.
6940. Baird, R. ..... Apparatus for preventing priming in steam boilers.
6941. Hahlo, Liebreich, & Hanson ..... Drop and circular box looms.
6942. Beardmore, W. ..... The manufacture of armour plates and apparatus therefor.
6946. Jackson, Bentley, & Nuttall ..... Apparatus for grinding or treating pulp for use in paper-making.
6949. Key, W. ..... Treatment of the discharge gases from gas engine cylinders.
6950. Riley & Boswell ..... Valves.
6959. Kent, H. ..... Gearing for the transmission of power.
6962. Dutton, S. T..... Railway signalling apparatus.
6976. Couves, C. C. ..... Apparatus for delivering oil about a ship at sea.
6982. Horn, W. W. ..... Printing presses (*Lawrence*).

23rd April, 1891.

6988. Ashworth & Ashworth Carding engines.
6990. Weston, G. ..... Method of relieving steam or other slide valves.
6991. Stott, J. H..... Running off machines.
6999. Fisher & Murgatroyd Apparatus for cleaning and lustreing yarns of silk or other fibrous substances.
7001. Fawcett & Hartley..... Stop rods in looms for weaving.
7002. J. H. Collins & Sons ... Crushing and pulverising machine.
7008. Horrocks, J. ..... Safety and anti-vacuum valve.
7015. Evans, A. G. ..... Railway signalling apparatus.
7024. Foster, C. J. ..... Pulp screening machines.
7038. Fiège, R. G..... Adjustable mechanism for drilling and other machines for determining depths of holes.
7047. Purnell, J. J. ..... Governor for gas and oil engines.

24th April, 1891.

7055. Monie, H..... Ring-spinning machines.
7061. Freakley, W. ..... Furnace and water circulator for steam boilers.
7062. Wilson, A. B..... Flax fibre carding machines.
7064. A. C. Caddick & Co..... Apparatus for making gas.
7068. Claringburn, J. A. ..... Knitting machines.
7072. Bradley, J. H. S. ..... Hammerless guns.
7073. Harrison & Harrison... Knitting machines.
7082. Mumby, G. ..... Indicating apparatus.
7084. Burton, B. ..... Machine guns.
7085. Brown, C. A. ..... Furnaces for steam generators.
7096. Morris, R. ..... Bolt locks for rifles.
7097. Smith, R. N. W. ..... Sliding cylinder in connection with a jacquard machine.
7108. Saunders & Sterzing ... Permanent way of railways.
7109. Fisher, F. W. ..... Safety valves.

25th April, 1891.

7115. Austin, H. K..... Construction of bearings for shafts and spindles.
7116. Higginson, J., Jun. ..... Revolving flat cards.
7117. Pickles & Pickles ..... Winding machinery.
7120. Partington, E. ..... Disintegrating fibres in the manufacture of paper pulp.
7128. Heathorn, T. B. ..... Apparatus for steering, propelling, and retarding the motion of boats.
7136. Knowles, T. ..... Carding engines with revolving flats.
7139. Common, A. A. ..... Improved locomotive engine.
7142. Denton, W..... Vertical or marine boilers.
7150. Lebédeff, N. ..... The manufacture of iron and steel.
7157. Altmann, A. ..... Governors for gas and petroleum motors.
7166. Dolder, A. A..... Carding machines.
7170. Young, M. ..... Printing machines.
7172. Scrymgeour, D..... Method of utilising liquid fuel in fire-boxes.
7182. Price, H. S..... Apparatus for the transmission of power by ropes (*Hall*).
7183. Snowdon, J. A. ..... The manufacture of pitch chains.
7185. Horn, W. W. ..... Bolt cutter (*Dutcher*).
7187. Lillie, S. M. ..... Evaporating apparatus. (26th September, 1890.)
7191. Morton, T. ..... Apparatus for the return of water of condensation to steam boilers.

ELECTRICITY.

20th April, 1891.

6767. Lucas & Garrett ..... The electrical production of ozone.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Steam and Air Engine.—*E. Field, London.*—According to this invention a mixture of steam and heated compressed air is used as a motive fluid in engines, which may be of any ordinary type, but it is preferred to use a well-jacketed compound engine; all pipes conveying the hot fluids should be well lagged. The general arrangement of the apparatus is shown in side elevation in Fig. 1 below. Air is drawn from the atmosphere and is compressed to any convenient pressure by a compressor A, worked by an extension of the piston rod of the motor B, as shown, or operated independently, as may be most convenient. After compression the air is passed through a pipe C into a heater D placed in the flues of a boiler E, the air being raised in the heater to a temperature of 400° to 500° Fahr., and being afterwards conveyed by a pipe F to a "mixer" G. Steam from the boiler is led also to the mixer by a pipe H, and the resulting mixture of steam and hot air is led to the valve chest I of the motor cylinder B by the pipe J. A pipe K with a suitable stop valve is provided for the passage of a supply of steam from the boiler to the valve chest when such independent supply is desirable at starting under conditions which will presently be referred to. Fig. 2 illustrates the mixer (lettered G in Fig. 1) in sectional elevation, L being the hot air inlet, M the air inlet valve, N the steam inlet, O the steam inlet valve, P being the steam nozzle, and Q the passage by which the mixture of steam and hot air passes to

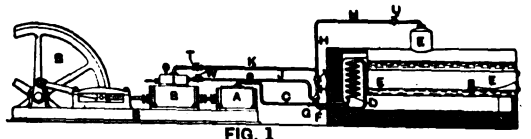

FIG. 1

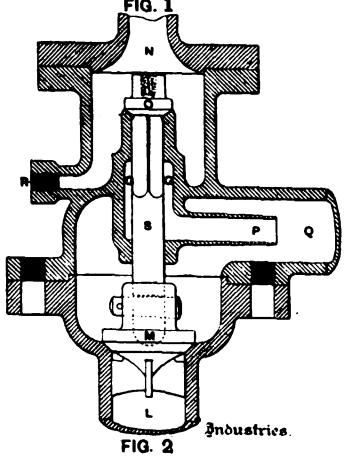

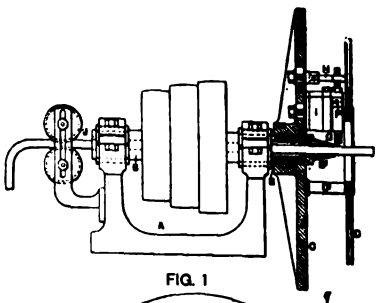

FIG. 2

the boiler. R is a drain for the withdrawal of water of condensation. It will be observed that the air and steam inlet valves are of different areas and are secured to a spindle S common to both of them in such a manner that the valves may both open or shut simultaneously; a compound regulator is thus formed, the areas of the valves being inversely proportioned to the pressure upon them in pounds per square inch, the pressure of the heated compressed air in this example being assumed as less than the pressure of the steam. The method of working is as follows:—The engine is started with steam only, by opening the valves T and U, the mixture main J and valve V being already open; after a few revolutions the compressor will have forced sufficient air through the heater to raise the pressure of the air up to that of the steam; the hot air valve M (Fig. 2) will then be lifted by the excess of air pressure, consequently the steam valve O (Fig. 2) will likewise be opened; hot air and steam will then rush through the mixer, forming a volume considerably greater in bulk than the mere aggregate of the volumes of the steam and hot air, but at a pressure equal to the mean pressure of the steam and hot air; and the engine will run faster, for if the volume of mixture be not used by the engine an increased pressure of mixture will be the result. The direct steam communication from the boiler to the engine will then be closed by the shutting of the valve T and the engine will continue running at its proper normal speed, the steam supply to the mixer being regulated by a governor or by any other suitable means at V or W, or the mixture may be regulated by a valve at W. Thus the valve arrangement above described is entirely self-acting, closing when full pressure has been attained in the slide jacket, and opening immediately on any reduction of pressure taking place in the slide jacket of the engine. When the mixture in the mixture main has attained approximately the same pressure as that of the compressed hot air in the hot air main, the compound valve will be in equilibrium, and both steam and hot air valves will be closed by the weight of the valves and stem, and will remain so until the pressure is reduced in the mixture main by the demand of the engine when the hot air valve will be relieved of some of the pressure on its upper side. To reduce the speed of the engine it is only necessary to throttle at V the steam passing to the mixer. The construction and operation of the mixer may be variously modified. Claims: The production and use of a mixed motive fluid composed of heated compressed air and of steam in proportions regulated by a mixer; the use of the mixer illustrated in Fig. 2, and the use of the whole apparatus, including other modifications of mixers described in the specification.—No. 4482. March 21st, 1890. 8*d*.

Apparatus for Armouring Insulated Wires.—*F. Walton, London.*—An apparatus for the above purpose is shown in the annexed illustrations, of which Fig. 1 is a side elevation, partly

FIG. 1

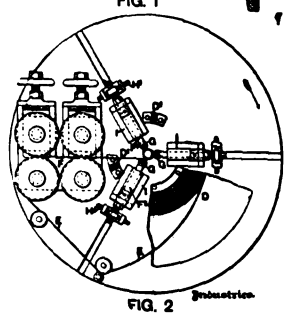

FIG. 2

in section, and Fig. 2 a front view. A is a lathe head carrying a revolving tubular mandrel B, with a face plate C, having at some distance in front of it a reel D carried by three studs D^1. On this chuck are also mounted guide rollers E and two pairs of corrugating rollers F, one of each pair having its bearings adjustable by a screw. Besides these rollers there are mounted on the chuck three pressing rollers G, each of them held in a stem F^1, which can be adjusted in two directions, in distance radially to or from the centre of the chuck by means of a nut F^2 and lock nut F^3, and in obliquity to the axis of the chuck by means of a wrench lever H fitting on the stem F^1 and adjustable by set screws H^1. The stem of each of the rollers G is fitted in a block I, which is bolted to the chuck. On the reel is wound a continuous length of metal strip, which is led by the guide rollers E somewhat obliquely between the corrugating rollers F and under one of the pressing rollers G. The insulated conductor is passed between grooved rollers, through the tubular mandrel B, its projecting conical nose B^1, and between the pressing rollers. The mandrel being caused to revolve, and with it the chuck and all the parts carried thereon, the strip unwinds from the reel, becomes corrugated in passing between the rollers F, and then by means of the pressing rollers G it is helically coiled around the conductor, forming a flexible tube which encloses it. The three rollers G, besides being adjusted each in respect of radial distance from the axis and of inclination to it, are fixed at such distances from the face of the chuck as to suit the helical pitch of the strip as it is coiled on the conductor, and the convolutions of the strip being pressed forwards by the action of the rollers G cause the conductor, which they enclose, to advance with them. Claim: For armouring an electrical conductor with metal strip coiled thereon in interlocking convolutions, the mandrel B, chuck C, reel D, corrugating roller F, and pressing rollers G, combined and operated substantially as described.—No. 21045. December 24th, 1890. 6*d*.

Breech-loading Ordnance.—*J. Astbury, Smethwick, Staffordshire.*—The invention has reference to breech-loading ordnance of a kind described in a prior patent, No. 670 of 1877, and consists of a mechanism for ejecting the case of the exploded cartridge. In the accompanying illustrations is shown at Fig. 1 a longitudinal section of the breech end of a gun, and at Fig. 2 an end view

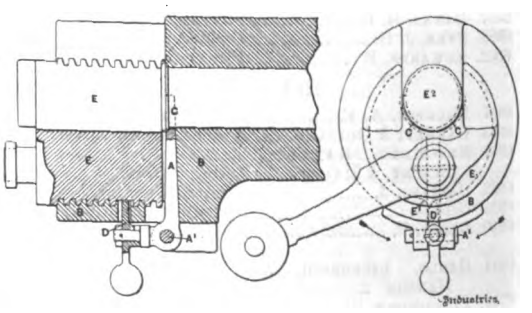

FIG. 1. FIG. 2.

of same with mechanism embraced by this invention. The bell-crank lever A is pivoted at A^1, and the vertical limb of which lies in a recess in the breech of the ordnance B. The upper end of this vertical part is bifurcated at C semi-circularly, and encloses the body of the cartridge, and also engages the back collar thereof. The lower part of the lever A extends horizontally rearward, and carries loosely a small trip lever D, the upper end of which projects upwards and within the breech B, and the lower end of which is counterweighted. There is a tooth E^1 provided on the bottom of the breech block E, which (at the particular moment of acquiring a full opening of the trough E^2 of the breech block, for the purpose of extracting the cartridge, when winding

Digitized by Google

the handle backwards as shown) engages the nose of the trip lever, and striking or pushing it out of its path, thereby deflects that lower limb of the bell-crank and consequently pushes, or jerks backwards, the spent cartridge case abutting on the back side of the bifurcation of the other limb. Claims: (1) In breech-loading ordnance, of the nature described, an automatic cartridge extraction gear, consisting of a bifurcated bell-crank lever, containing on its lower limb a trip lever, actuated by the prime motion only as imparted through the handle to the breech block, and transmitted from a tooth situated upon the latter, through the clutch, deflecting thereby, *en passant*, the lower limb of the bell-crank, and so discharging or extracting the cartridge case at the upper or bifurcated end of same; and which clutch, being clear, imparts no such motion to the bifurcation during rotation in the opposite direction, substantially as described; (2) in breech-loading ordnance, of the nature as described, the arrangement and combination of parts constituting the extraction gear.—No. 7116. May 7th, 1890. 6*d*.

Feed-water Heater.—*H. H. Lake, London.* (*G. H. Burpee, New York, U.S.A.*)—In the annexed illustrations is shown a feed-water heater constructed on the principle of this invention, and heated by the hot gases and products of combustion escaping into the smoke flue. Fig. 1 is a vertical transverse section, Fig. 2 a

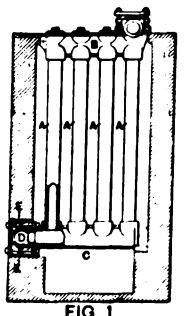

FIG. 1

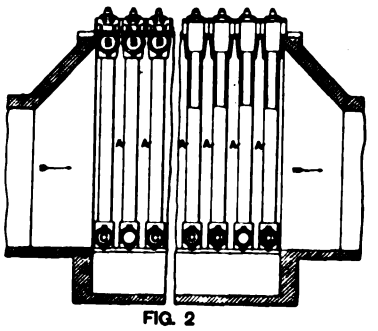

FIG. 2

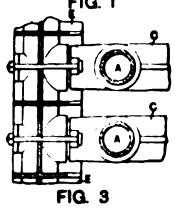

FIG. 3

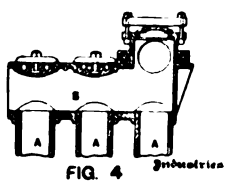

FIG. 4

partial and irregular longitudinal vertical section, and Figs. 3 and 4 enlarged details. A are the vertical circulating tubes, B the top boxes, C the bottom boxes, and D the lower longitudinal connecting pipe. The pipe D, which is held between the two plates E, is provided at one side with nipples to receive the ends of the pipes C which are made tapered, and has at the other side, opposite said nipples, hand holes covered by plates held fast by T bolts, the heads of which engage slotted projections on the pipes C (Fig. 3). The lower ends of the vertical tubes A are tapered, so that the ends are smaller than the central part of the tube. The upper ends of the said tubes, however, are so tapered that the ends are larger than the centre of the tubes. These tubes are passed through the hand holes in the upper box B, and when the lower end has entered the nipples in C pressure is applied to fix them. The covers for the hand holes in B are fixed substantially as shown (Fig. 4). Five claims are made.—No. 21243. December 31st, 1890. 8*d*.

Crushing Mills and Amalgamators.—*C. E. Hall, Sheffield.* (*Chas. Morel, Grenoble, France.*)—This apparatus is for the purpose of crushing, grinding, and sieving hard substances in the presence of a liquid, and it consists of one or more hard metal or

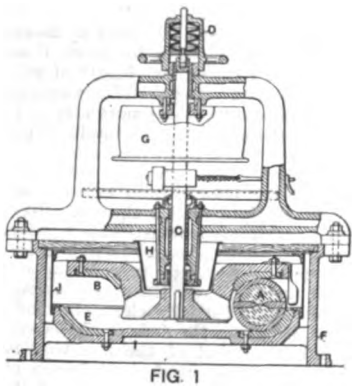

FIG. 1

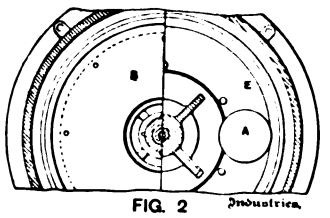

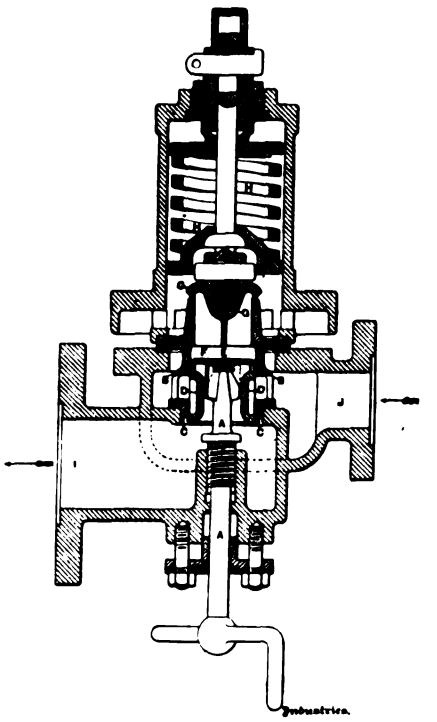

FIG. 2

other balls rolling in a circular path upon a horizontal fixed ring, against the side of which they are pressed by their centrifugal force. Fig. 1 is a sectional elevation and Fig. 2 a sectional plan of a modification of this invention, in which a ball A is driven by a circular disc B keyed to the vertical spindle C and pressed upon the ball by its dead weight or by a suitable arrangement of adjustable springs D, which are sufficiently elastic to permit the disc to rise in the event of any matter of exceptional hardness coming between the ball and the renewable wearing path E bolted to the fixed frame F. G is a belt pulley for driving the vertical spindle C. H an annular opening through which the material to be crushed is fed, together with water, I is an agitator for driving the crushed material through the screen J (whose perforations are not shown). Other modifications of the apparatus are described, in one of which several balls are forced round upon a circular track by radial pushing arms attached to the vertical driving shaft of the machine, which in this instance is driven from below by bevel gear. Copper amalgamating plates, corrugated and otherwise, are employed with a quicksilver filling for catching the free gold resulting from quartz-crushing. Claims: The three modifications of apparatus described in the specification, including a corrugated amalgamator and delivery shoot.—No. 17520. November 1st, 1890. 8*d*.

Bending Machine.—*R. Kelly, Liverpool.*—The object of this invention is to provide a machine or tool whereby metal pipes and round, flat, or angle iron or other metal may be readily bent into any required curve, and the apparatus described consists of a lever into which are fitted wheels, free to revolve on pins passing through their centres and also through the lever. The said wheels have plain or shaped edges to suit the material operated on. One of the pins is fixed to a stationary bed-plate, whilst the other pin moves with the lever. On the bed-plate is an adjustable cramp piece. The material to be bent is placed between the wheels, one end is secured in the cramp, and the handle or lever is turned round the stationary centre so that the free end of the material is bent to the desired extent round that one of the wheels which turns upon the same centre as the centre about which the lever rotates; the size of this latter wheel determines the radius of curvature. The cramp is an eccentric friction piece of a well-known type. Claims: The bending machine as described.—No. 8038. May 23rd, 1890. 6*d*.

Reducing Valve.—*J. & G. Weir, Cathcart, N.B.*—This is a semi-automatic apparatus, in which the screwed spindle A may be screwed up to keep the loose double-beat valve D on its seats B C, or screwed down to allow it to fall away therefrom; the

valve not being attached to the spindle is, therefore, free to move up and down when the spindle A is not in the closing position. The top of the admission valve is made with a disc E attached to it by webs, the disc fitting quite loosely in a cylindrical part of the chamber F formed in the same piece as the valve seats. At the top of this chamber is a spring-loaded escape valve G, the spring H being adjusted to correspond with the maximum pressure to be admitted to the evaporator or other apparatus by the passage L. J is the inlet for the steam from the boiler. Should the pressure within the admission valve and in the passage I rise beyond the prescribed limit steam will leak past the edge of the disc E, lift the valve G and escape, attracting the attention of the attendant, who will then adjust the admission valve D by means of the spindle A, closing it until pressure is so reduced in I that steam ceases to escape past the disc to the spring-loaded escape valve G. Until this adjustment is made the action of the escaping steam upon the disc E will close the valve D sufficiently to prevent the pressure in I from becoming too great. Claims: The combination illustrated, consisting of the equilibrium valve and its adjusting spindle, the disc attached to the valve and working in a cylindrical chamber, and an adjustably loaded escape valve.—No. 7967. May 22nd, 1890. 6*d*.

Grease Cups.—*E. H. Benners & S. Leach, Elisabeth, U.S.A.*—This grease cup is arranged to deliver automatically grease to the moving parts of machinery in accordance with the speed at which those parts are working, and consists of a cylindrical cup having a plunger fitted therein in connection with a weighted disc adapted by the motion of the parts to successively vibrate against the plunger to force the latter against the grease contained in the cup or cylinder, the supply being greater as the speed increases and less as the speed diminishes. Two examples are shown, in which a gravity plunger is fitted within a cylindrical oil container, and, upon a spindle carried by the plunger, is a disc caused to travel up and down within certain limits, the oil cup or chamber being intended for use upon moving parts of machinery. The faster the oil cup vibrates or reciprocates the harder will the disc strike the plunger, and the greater will be the quantity of grease forced out of the oil cup by the plunger. A pair of washers are placed at the opposite ends of the path of the disc to prevent noise as far as possible. A small air passage is formed in the spindle of the plunger, and is controlled by a screw in order to permit the plunger to be removed to refill the cylinder, otherwise removal of the plunger would be difficult, as a partial vacuum would be formed below it. Claims: A grease cup as described, with a plunger and movable disc for hammering the same, with a screw adjustment on the plunger spindle to limit the travel of the disc.—No. 3436. February 25th, 1891. 6*d*.

Water Gas.—*Hugh Williams, Stockport.*—This invention has for its object the production of a permanent illuminating gas consisting of hydrogen gas produced from the decomposition of superheated steam in combination with other gases obtained by the decomposition of air, liquid hydrocarbons, and carbonaceous

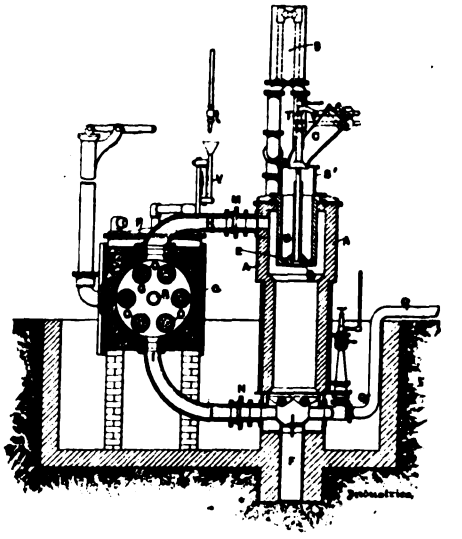

FIG. I.

matter. A portion of the apparatus is shown in sectional elevation in Fig. 1, and in side elevation partly in section in Fig. 2. A pair of gas producers A A^1 are worked together, the operation being commenced in one producer and partially completed in the other, each serving alternately as primary and intermediate producer, the working of the pair being to a certain extent continuous. Each producer is fitted with a distilling retort B B^1 charged with fuel through C at its upper end and discharging the resulting coke at its lower end into the corresponding producer for fuel by the valve D, which is provided with free holes E for reasons which will be seen later; each producer has also rocking grate bars operated from the exterior, and a siphon ashpit F. The producers are started by being charged with fresh fuel, which is lighted and brought to a state of high incandescence by the establishment of an air blast and through draught maintained for the desired period, the retorts B being also charged with fuel, which, when sufficiently carbonised by the heat of the hot gaseous and solid contents of the producer A, is allowed to fall into the producer and the retort receives a fresh charge. Each producer is connected with the interior of a fixing retort chamber G by a pair of gas passages H I or J K controlled by valves at M M^1, N N^1, a passage proceeding from the upper end of each producer into the chamber G at its upper side, and the other two passages proceeding from lower end of producer to the lower side of G. The chamber G contains six fixing retorts O each charged with fragments of iron, and a carburetter P provided with internal baffle plates is mounted on the top of G so as to receive heat

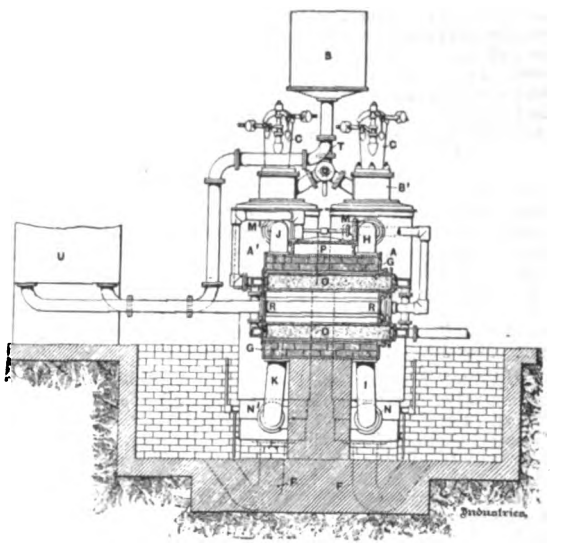

FIG. 2.

therefrom. When the operation of gas production is commenced in producer A, for example, the retort B^1 in the companion producer A^1 is charged with fresh fuel and steam from an injector and combined with the air which has been passing into A by a pipe Q, and the valve at N being shut the gases resulting from the air, steam, and carbonaceous matter in A pass from the upper part of that producer into G and around the retorts O and pipe R therein, heating them, and, passing out at the lower side of G by the pipe I, flow into the lower end of the adjoining producer A^1, into which a jet of steam is simultaneously introduced, the whole passing up through its contents, and (the valve at M^1 being

Digitized by Google

closed) forcing its way through the holes E into and through the heated contents of the retort B^1, aiding the carbonisation therein, and, mingling with the gases which have already begun to rise, passes to a condenser D by the pipe T controlled by a valve permitting only one retort to communicate with the condenser at a time. The interior of the condenser is so arranged that tar and other matters which may form may gravitate back into the retorts, and anything failing to be carbonised therein goes into the producers so that ultimately all the fuel is converted in gas and ashes. Going onward from the condenser the gases pass through scrubber U, thence through reheating tube R, to the carburetter P, into which hydrocarbon liquid runs at V to be vaporised, the gas thus carburetted proceeding to the retorts O of the chamber G in which it is fixed, any water vapour present being also decomposed and free oxygen eliminated. From the fixing retorts the gas is taken to holders for storing. When this cycle is completed the valves at M M^1, N N^1 are readjusted, and a similar operation to that commenced in retort A now commences at retort A^1. Claims: The apparatus as shown and described; the gas producer provided with a retort, means for charging and for discharging the contents of the retort into the producer as fuel; also such gas producers in pairs worked as described above, and with connections so arranged that the tar and products of condensation flow back into the retorts; the fixing retorts charged with fragments of iron and means for highly heating same in combination with the foregoing and with the purifier and liquid hydrocarbon carburetter. The process as described for the manufacture of illuminating gas.—No. 5434. April 10th, 1890. 11*d*.

Expansion Gear.—*W. Walker, Salford.*—This invention consists of a trip gear in which the point of cut-off is automatically controlled by the governor. Figs. 1 and 2 illustrate the arrangement in side and end sectional elevation as applied to a Cornish cut-off valve, but it may be conveniently applied to the valves at opposite ends of steam engine cylinders, as will be understood. Fig. 3 is a view of the toggle or detent in section. A hollow sleeve A is oscillated to and fro through a constant range by the engine, which vibrates the arm E at each revolution; within this hollow sleeve is a pair of discs B, which alternately operate the valve by pins C. These project from each disc and raise and

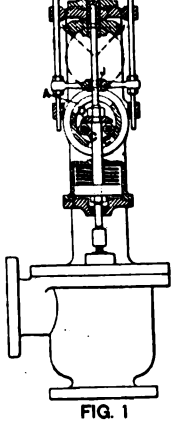

FIG. 1

FIG. 3

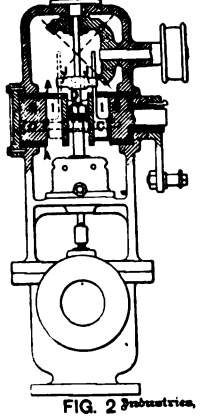

FIG. 2 Industries.

lower the collar D on the valve stem. The sleeve and discs are caused to rotate together, so long as a detent or toggle formed upon the short arm of a double-armed lever F carried by each disc and moving therewith bears against a portion G of the sleeve. Each lever is kept in its working position by a spiral spring enclosed in a cylindrical box I, and the stops J are adjustable by the governor H in the path of oscillation of the longer ends of the double-armed levers F, which must sooner or later come into contact with them, whereupon the short arm of one or other of the levers will be caused to compress its spring and release the disc from the influence of the sleeve A, leaving the former free to be rotated by any conveniently rapid means to allow the valve to close sharply, the valve being eased down by a dashpot at the lower extreme of its fall. Claims: The curvilinear bell-cranked or double-armed lever with a "toggle end," and working on a single pin joint, and kept in its driving position by a spring enclosed in a circular box; the hollow sleeve and the driving discs in combination with the foregoing.—No. 6899. May 5th, 1890. 8*d*.

Expansion Valves.—*G. & J. Stones, Smethwick.*—In this expansion valve an ordinary D valve is formed in a single casting with an outer shell, whose walls come down on to the port faces; the steam passages formed in the space between the laps of the valve and the inside of the walls aforesaid communicate each with a separate chamber formed by a division extending across inside the external shell in the line of the travel of the D valve. A cylindrical tube open at the ends passes through the outer shell and through the central partition in a direction at right angles to the line of travel of the D valve, and in this tube are two ports, communicating separately with the chambers supplying the opposite ends of the D valve with steam, these ports being controlled by a piston valve which slides in the cylindrical tube above referred to, and constitutes an expansion valve. The two valves, although, in a sense moving together, can be worked and regulated quite independently of one another, the movement of the main valve, for example, having no influence upon the operation of the expansion valve which would not be the case with the ordinary arrangement of expansion valve working upon the back of a main slide. Claims: An expansion valve forming part of a D slide valve and arranged as described, so that the motion of one valve can be regulated and determined without regard to the motion of the other.—No. 7264. May 10th, 1890. 6*d*.

Tube Bending Machine.—*John Laidlaw, Glasgow.*—Fig. 1 below is a plan, and Fig. 2 a part side elevation showing the rollers of a machine in which tubes may be bent without the necessity of filling the interior of the tube with material in order to prevent it from crumpling during the process. The peripheries of the semi-circularly grooved rollers A are maintained in contact, and advantage is taken of the fact that the act of bending a tube tends to make it oval in cross section, the widest portion being at right

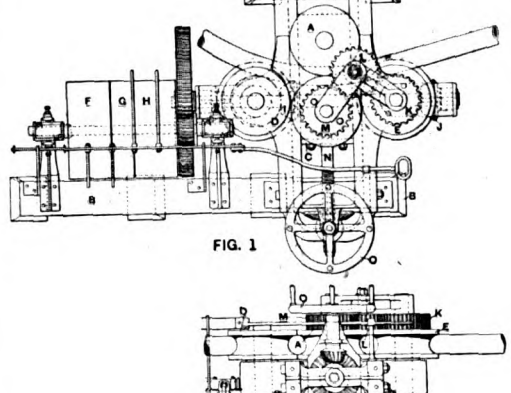

FIG. 1

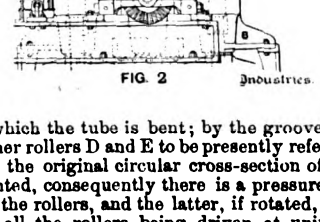

FIG. 2 Industries.

angles to the plane in which the tube is bent; by the grooves in the rollers A (and in other rollers D and E to be presently referred to) being formed to fit the original circular cross-section of the tube, ovalling is prevented, consequently there is a pressure set up by the tube against the rollers, and the latter, if rotated, will draw the tube along, all the rollers being driven at uniform speed. B is the machine frame or table, C is a slide which carries the two rollers A upon fixed centres, D and E are rollers which rotate upon centres secured to the frame, and are driven by any convenient means, such as the pulleys F G and H and spur gearing, operating a shaft carrying the bevel wheels I and J gearing with bevel wheels secured to the rollers D and E. The roller E is geared to one of the rollers A by spur wheels K L and M, which are maintained constantly in gear by means of the linked frame shown, and a screw N operated by the hand-wheel O serves to adjust the frame carrying two rollers A relatively to the stationary rollers D and E, so that the curvature of the tube may be varied. Claims: In bending machines the two rollers A, grooved, and movable together, in combination with the two fixed rollers, to give the curvature; the linked frame and driving gear K L M, and the arrangement of gearing by which the rollers A A D and E have uniform surface velocity.—No. 9500. June 19th, 1890. 6*d*.

ELECTRICITY.

Cut-outs.—*F. Bryan, London.*—The inventor's object is to provide an instrument which can be adjusted to brake an electric circuit whenever the current attains a predetermined strength. Referring to the accompanying illustrations Fig. 1 is a front view, Fig. 2 a plan, and Fig. 3 an end view of an instrument for the above purpose. A A^1 are two mercury cups, the former fixed to the base B and connected to terminal C, and the latter fixed to metal frame D fixed to B and connected to terminal C^1. An iron bar E bent to a circular curvature is fixed adjustably in D. A

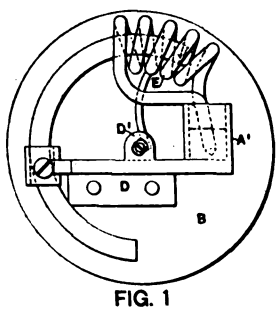

FIG. 1

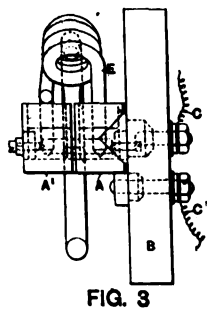

FIG. 3

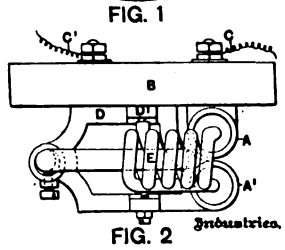

FIG. 2 Industries.

coil of copper wire surrounding but not touching E is carried by an arm pivoted to the frame D at D^1, and has its two ends projecting into the cups A A^1. In the position shown the circuit is completed from C through A, the coil F, A^1 and D to C^1, but should the current become too strong the coil will be attracted by the core and the circuit broken. By adjusting the length of the core projecting into the coil the movement of the latter may be made to take place under various strengths of current. Claims: An appliance for cutting out an electrical circuit when the current exceeds a certain strength, wherein a wire coil, enclosing an adjustable magnetic core and forming part of the circuit while it is in a certain position, is pivoted so that when the strength of current causes a certain amount of mutual attraction between it and the core, the coil is made to move out of position and so to open the circuit, as described.—No. 7422. May 13th, 1890. 6*d*.

CHEMISTRY.

Colouring Matters.—*The Society of Chemical Industry, Basle, Switzerland.*—The production of red basic colouring matters by condensation of the alkyl derivatives of meta-amidophenol with succinic acid anhydride has already formed the subject matter of a series of patents, and, according to the present invention, analogous dyestuffs are obtained from the condensation product of resorcine with succinic acid (resorcine-succinëine) by the action of secondary amines at a higher temperature. The reaction with dimethylamine proceeds in this operation in a manner quite analogous to that with the fluoresceine. For the production of the succinic acid-rhodaminol or the succinic acid-rhodamine the following may serve as an example:—13·2 parts of resorcine-succinëine and 13·8 parts of a solution of 40 per cent. of dimethylamine are heated, together with 70 parts of alcohol, in a close vessel up to from 170° to 200° C. during fourteen hours. The product of the reaction is then diluted with water, and, after the addition of 21·9 parts of soda lye of 33 per cent., is heated in the water bath for the purpose of the evaporation of the alcohol and of the superfluous dimethylamine. The alkaline solution is then agitated repeatedly with ether or toluol, the colouring base of the succinic acid-rhodamine passing over into the ether, whilst in the aqueous solution the succinic acid-rhodaminol remains dissolved in the form of its soda-salt. The latter is separated and is finally obtained pure. The soda-salt and the potassium-salt dissolve easily in water, showing a red colour, also in alcohol, and they dye on silk in the soap bath a light pink colour. From the aqueous solutions acetic acid and dilute mineral acids precipitate the disengaged succinic acid-rhodaminol in the form of a red-brown magma, which dissolves with difficulty in water and dilute mineral acids, but easily in alcohol. For the separation of the succinic acid-rhodamine the above-mentioned extract in ether of the reaction-mass is agitated with a little warm dilute hydrochloric acid or is treated with hydrochloric acid gas, whereby the dissolved colouring base is eliminated in the form of its hydrochlorate. This latter separates out as a green-glistening crystalline mass, which is purified by re-dissolving in dilute hydrochloric acid. Claims: (1) The preparation of succinic acid-rhodaminol and succinic acid-rhodamine from the condensation product of resorcine with succinic acid, by the action of dimethylamine at a temperature of 170° to 200° C., substantially as herein described; (2) the succinic acid-rhodaminol colouring matter, produced as described.—No. 10047. June 28th, 1890. 6*d*.

MISCELLANEOUS.

Nut and Pipe Wrench.—*D. H. Carpenter, Orlando, Fla., U.S.A.*—The upper jaw of this wrench has one or more transverse notches or grooves having salient edges to bite the surface of an object to be acted upon rather than to bear against the sharp angles thereof, which are received into a groove. The upper jaw is combined with a jaw, which may be either fixed or movable and adjustable in relation to the first-named jaw, and which is arranged so that an angular object placed between the two will be engaged on its sides and not at its angles or corners. The acting surface of the movable jaw is eccentric to adapt the wrench for use on pipes. The eccentric jaw has teeth which engage with teeth on the wrench, and secure in position the jaw and the movable saddle which carries it. Claims: A wrench as above described, provided with a fixed or movable jaw, whose active or gripping surface is eccentric; the saddle carrying the movable jaw and the teeth on the latter and on the fixed bar are claimed for the purpose described.—No. 2450. February 10th, 1891. 6*d*.

Manufacture of Brushes.—*H. Waters & W. Woodman, both of Birmingham.*—A slide moved vertically by means of a treadle carries a tool for bending staples of the usual U-shape, and also a tool which cuts from a continuous length of wire a piece long enough to form one staple. Any well-known mechanism is used for feeding the continuous wire intermittently to the cutting off and bending tools. Adjacent to the staple former is a trough containing the bristles which lie at right angles to the wire from which the staples are formed. A slide with fingers carries a certain quantity of the bristles into position underneath the formed staple, and at right angles thereto. The centre of the bunch of bristles lies over a trumpet-shaped guide, at the lower end of which a brush-back is placed having holes therein. An inserting tool causes a staple to descend upon the bunch of bristles, which it pushes down the trumpet-shaped guide, the inclined mouth of which partially closes the ends of the staple together, and also bends up the ends of the bristles. The continued downward movement of the inserting tool forces the staple and the lower part or bend of the bunch of bristles into the hole in the brush back, where the ends of the staple come into contact with a clenching tool, which is in position at the opposite side of the brush back, and which bends out and clenches the staple against the latter. Claims: Securing bunches of brush bristles by staples having ends which are clenched over; the combination of the inserting tool, the trumpet-shaped guide, and the clenching tool, together with a staple-forming device; means for collecting measured quantities of bristles and placing them in position under the inserting tool.—No. 4338. March 20th, 1890. 1*s*. 1*d*.

Copies of the British specifications may be obtained on application to H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

A JAPANESE COMMERCIAL MUSEUM.

THE illustrations given in Figs. 1 and 2 represent a front view and a ground plan of a Commercial Museum erected at Osaka, Japan. Although an attempt was made some four or five years ago to fully establish one in Tokio, which was to have been maintained by the various Departments of Agriculture and Commerce, of Foreign Affairs, and of Education, and by the Chamber of Commerce, it is still to some extent unsuccessful. The museum at Osaka, as will be seen, is divided up into various sections. On the ground floor are the sections of exports, packing, and drugs, medicines, and spices, while there are also on this floor a laboratory, general office, and reception room. On the first floor are the sections of imports, and domestic products and manufactures, with a library, an advertisement room, and meeting rooms. There is also an agency for facilitating and introducing sales and purchases of domestic and foreign articles.

From a printed report, which emanates periodically from this museum, we find that all articles exhibited there are provided with an explanatory notice giving the place and date of purchase, place of production, cost, &c., so that local productions may be compared with those of foreign countries. A commercial college, we are informed, is also in progress, which will further assist to place Osaka at the head of Japanese commercial cities.

THE INSTITUTION OF MECHANICAL ENGINEERS.

(*Concluded from page* 441.)

MR. MARSHALL said he had not expected to be called upon so early in the discussion, but there was one point which no doubt had struck all present. He alluded to the enormous size of the boilers in this vessel. He thought that with a heating surface of nearly 5 square feet per indicated horse-power, the boilers should certainly give twice the power they did. The temperature of the funnel gases appeared to him to be low: in the s.s. "Colchester" trials they reached 800° Fahr., while the engineer of the "Iona" got 672°, a fact which he could not understand if tested in the flame box. (Mr. Fothergill here explained it was taken in the uptake.) He thought the results of these trials demonstrated the desirability of forced draught, as they showed a better combustion, lower temperature of gases, and a shorter and more manageable length of grate than could have been obtained under natural draught. He acknowledged his indebtedness to Professor Kennedy's data for much valuable information.

Mr. J. Fiddes Brown (the chief engineer of the "Iona") said that he wished to preface his remarks by a few words in explanation of the reason why he made the subsequent trial, especially so when it was so closely preceded by such an elaborate and careful trial by Professor Kennedy. He said that at the expiration of the Committee's trial, and when the results were roughly estimated, they did not appear quite as good as he had anticipated, and as compared with the coal consumption of the two previous voyages, which was a mean consumption during about 150 steaming days. The consumption of coal was not nominally higher during the trial, but he expected it to be less, because about 50 per cent. of the coal burnt during the 150 days was received from foreign coaling stations. With the supply from these stations the loss is often more than 10 per cent., due to shortness of weight and inferior quality, so that the mean consumption during the regular voyage would include this loss, and also the steam for the steering engine, which is supplied from the main boilers. He therefore expected that the coal consumption in the Committee's trial, where the coal was carefully weighed, would show better results than under ordinary circumstances. There appeared to him one or two conditions under which the Committee's trial was made which tended to affect the result, and that was his main reason for making the subsequent trial. The temperature of the feed-water during the Committee's trial was about 50° below the usual temperature, and this he thought indicated that there was a considerable loss of heat through the water passing to, and being retained in, measuring tanks. The supplementary water during the Committee's trial amounted to 6·1 per cent. of the total feed-water, which was a very excessive amount. If the excess were only 5 or 10 per cent. it might be neglected, but it amounted to fully five times the usual quantity. It was no doubt supplied and measured, but he thought that 80 per cent. of it never got farther than the feed pumps through leakage of the feed pump glands. The supplementary feed diagram graphically represented a record during nine days' voyage previous to the trials he made.

A JAPANESE COMMERCIAL MUSEUM.

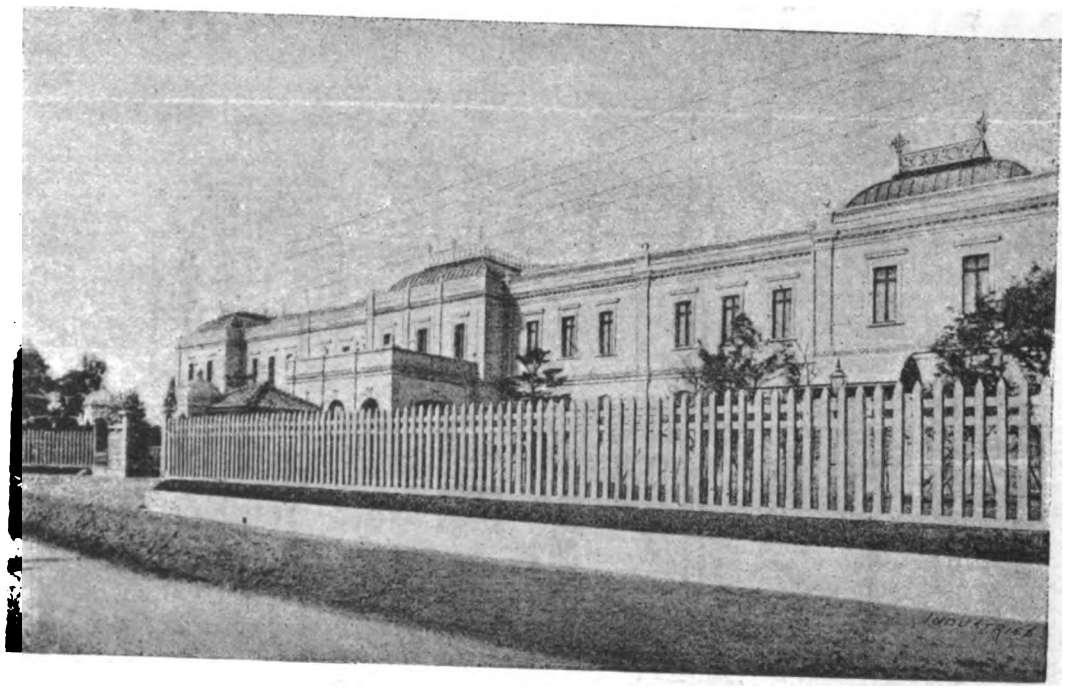

FIG. 1.—FRONT VIEW OF BUILDING.

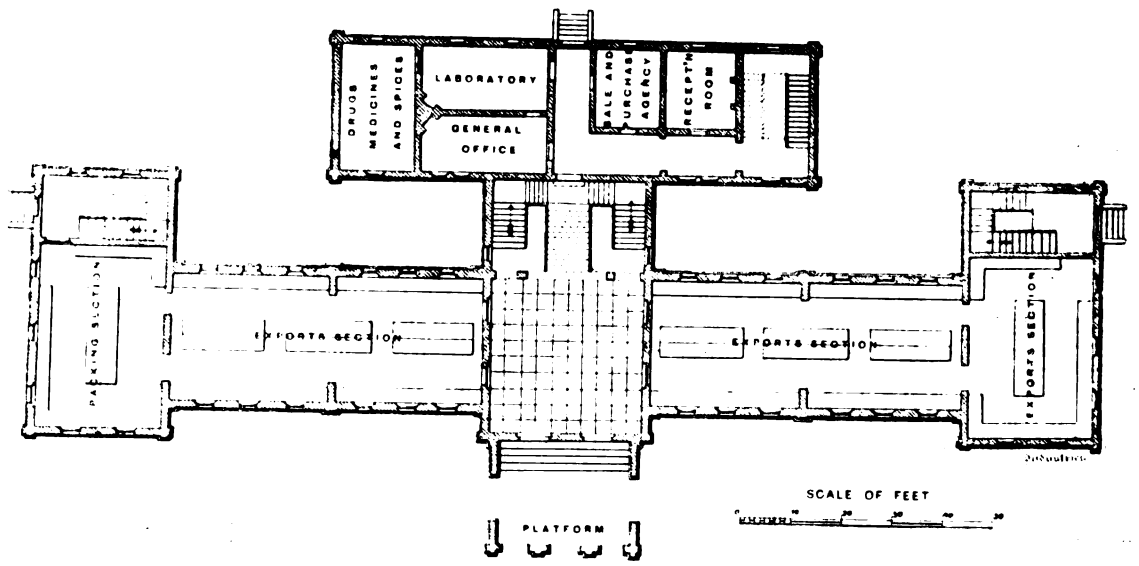

FIG. 2.—GROUND PLAN

The mean of the diagram equalled 1·28 per cent. of the total feed. From 4.40 p.m. on the first day recorded to 4.30 p.m. on the second day—during which no supplementary water was added—the boiler levels fell 1⅞in., equal to a loss of 2,212lb. of water, or 1·13 per cent. of the total feed.

To estimate correctly the amount of heat carried away by the furnace gases, the temperature ought, he thought, to be taken as near as possible to their exit from the tube boxes, as was done in the second trial, and not half-way up the funnel as in the Committee's trial. From a series of simultaneous observations with a pyrometer in each position, he found an increase of 105° Fahr. at the lower position, which was 23·5ft. below the top position. This suggested that the temperature of the gases on leaving the tube boxes would be 452° + 105°, or 557°. There was about 110° Fahr. excess in the second trial to account for, which was probably due to a less weight of air being used. He was unable to estimate the weight of air directly, not having any means for taking samples of the furnace gases, but he thought an approximation could be arrived at by estimating the velocity at which the air passed at each furnace and chamber valve. The mean differences of pressure as shown by the water gauge were:—First trial between sides of valve openings, 0·55in. at ash-pit and 0·34in. at combustion chamber; second trial, 0·45in. at ash-pit and 0·78in. at combustion chamber. The temperature of the air was 123° and 62° at the first trial, and 133° and 80° at the second trial respectively. Knowing exactly the amount at the first trial from Mr. Wilson's analysis, he said there could thus be found the coefficient of efflux for these particular openings, which would be the same in both trials. On this basis 22·9lb. of air was used per lb. of coal in the second trial, 14 per cent. of which passed direct to the combustion chambers, whereas in the first trial only about 8 per cent. passed direct to the chambers. He thought that the mean indicated horse-power in the second trial could safely be considered under the true power, the indicators being connected by the usual long pipes and bends. Shortly before the first trial was started, a set of diagrams was taken at 64 revolutions and 155lb. boiler pressure, the indicators being connected as in the first trial. The diagrams represented 733 i.h.p. The steamer, he said, had the same deadweight in both trials, and the weather was similar, and if we supposed the power to drive a ship to vary approximately directly as the cube of the speed, and compared either the speed per hour or the revolutions in this manner, the horse-power would be about 738—which is an increase of about 4 per cent. on 707 i.h.p.—the mean of the diagrams. Taking the power as given by the long-pipe connection diagrams as 733 i.h.p., the coal consumption would be reduced during the second trial to 1·33lb. per indicated horse-power per hour, and assuming the feed water to be 12·69lb. per indicated horse-power per hour, the evaporation during the second trial would be 9·5lb. of water per lb. of coal at the feed temperature.

Mr. Willans traversed the causes which led to the good results shown. Referring to jacketing, he thought 4 per cent. of jacket water exceedingly small. In his opinion the great thing was to work a boiler moderately, and an engine as hard as is possible.

Mr. Burstall desired to correct Mr. Mudd's observations as to the leakage from the feed. He had charge of this particular section of the trials, and gave it as his

Digitized by Google

STEAM ENGINE GOVERNORS.

(*For description see page* 459.)

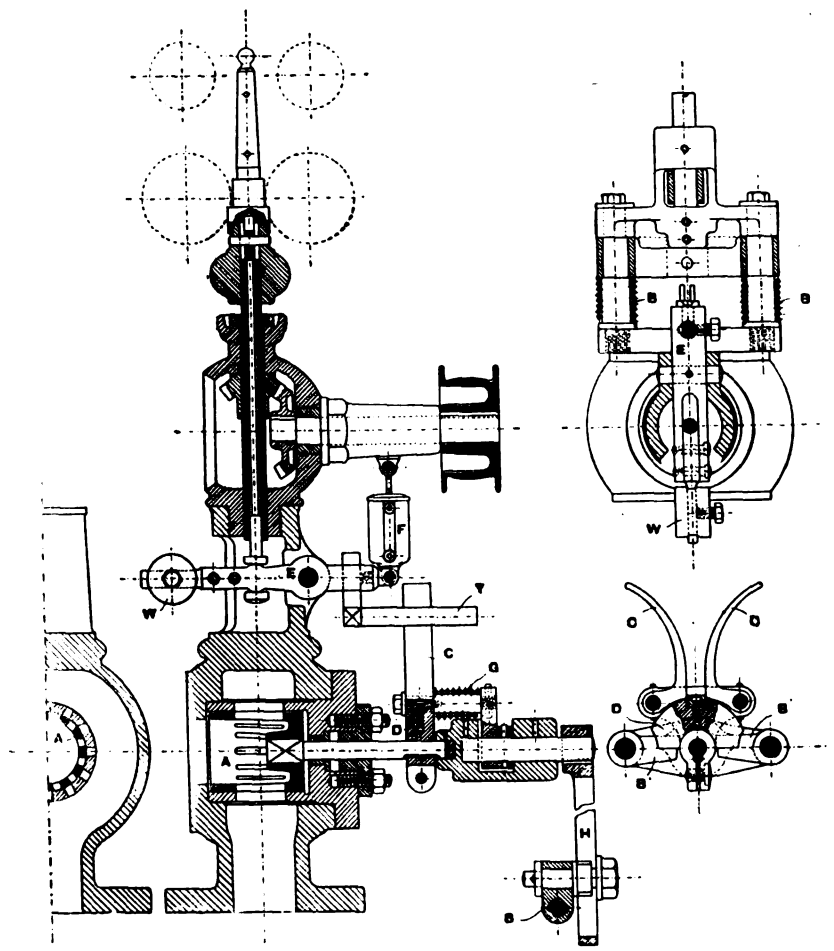

FIG. 14.

opinion that the leakage was only small, being about 200lb. in all, in place of the 3,000lb. as stated by Mr. Mudd.

Mr. Terry joined issue with Professor Kennedy on his estimate of the paper before them. He did not consider the paper at all a dry one. He was associated with the manufacture of forced draught machinery, and he should like to know the actual volume of air used, and the leakage of air past the corrugations of the furnaces and the bars in the immediate neighbourhood, as this appeared to him a point where considerable loss might occur.

At this point the meeting was adjourned to the following evening.

On the resumption of the proceedings on Friday, Mr. Halpin said he thought the Institution should be congratulated on the success of the paper. He was of opinion that it would be better to measure the feed-water by meter instead of the tank arrangement, and thought the amount of circulating water should be given in future trials. He would also like to know whether better results followed the use of small condensers with a large quantity of water or *vice versâ*. He thought the jacket question had not been carried far enough, and opined better results would have followed if the intermediate cylinder had also been jacketed. He was glad to find flat valves worked so satisfactorily, but thought the clearances abnormally large. He agreed with Mr. Marshall that the boilers were enormous; in fact, he regarded a boiler as a machine tool, and in this case thought the output, or efficiency, was low. While acknowledging it as a step in the right direction to keep the furnaces small, the chimney appeared to him to be six times too big, and the ratio of 6 to 1 far too large. Under these circumstances he failed to see the use of forced draught so far as this trial was concerned, as the quantity of coal burned per foot of grate was comparatively so small that he thought the Committee would have done better to have stopped the whole thing—*i.e.*, forced draught. The speaker controverted the figures given on page 15 of the paper, as to thermal units, and thought units per hour per square foot transmitted would be better. He stated that in Mr. Longridge's paper, read before the Institution of Civil Engineers, this was shown to be 11 units per square foot per hour, whereas in the "Iona" it was only $2\frac{1}{4}$.

Mr. Schönheyder, referring to the trial, wished to know why the Committee changed from the main feed pump to the donkey pump. The speaker thought the feed and air pu np diagrams perfectly useless in this case, and unreliable. He thought the makers were right in giving the large proportions of boilers that they did.

Mr. Phillips thought it would be desirable to take a diagram from the under-side of the air pump bucket. In his opinion the machinery was far too powerful, and quite ample for 1,000 h.p., and, under these circumstances, he failed to see the necessity for forced draught. He was of opinion the engines must have been very much linked up, and asked if it would not have been better to have worked with lower boiler pressure and links more open. The speaker dealt with the diagrams to show that the results as to pressure and horse-power were not what might have been expected. He took it that the steam was very much wire drawn, and regretted that the arrangements for testing the priming had broken down, as, if boilers so lightly driven primed, he could not conceive of any boiler being constructed which would not prime. Regarding the supplementary feed he found on working it out that this was simply enormous, and should certainly be looked into.

Mr. Bruce considered the value of these reports to consist mainly in the basis they formed for comparison, and considered the "Iona" had great advantages in regard to the excellent quality of the coal used, to which he in great measure attributed the excellence of the results obtained. In his experience, boilers of equal size yielded 800 h.p. readily, and he thought the results of the trial would not prove encouraging to shipowners. The speaker referred to the general arrangement of the forced draught, and asked why all the air was put under the bars, and not divided between top and bottom, a method, he understood, Mr. Fothergill advocated in a previous paper, and concluded by challenging the method of obtaining the temperatures.

Mr. McFarlane Gray thought the experiments very satisfactory. Speaking of the calorific tests, he wished to know if the latent heat of the steam had been deducted from the results, and pointed out the error that would have arisen if such had not been done. In referring to the funnel damper being only one-sixth open, with the object of keeping heat in contact with surfaces as long as possible, the speaker dealt with the questions of heat by radiation and conduction, and ridiculed the idea of "bottling up" the gases where heat was to be gained by conduction only.

Mr. Mair-Rumley thought all the members would join with him in thanking Professor Kennedy for the valuable services he had rendered to the Institution. In his opinion the boilers and engines were decidedly large for their work. The speaker called attention to the fact that, whereas the engines of the "Iona" showed twenty-one expansions, and those of the "Meteor" only nine expansions, the efficiencies of the two sets of engines came within about 2 per cent. of each other. Referring to Mr. McFarlane Gray's deprecatory remarks as to "bottling up" the gases, he would point out the fact that in mill engine trials the damper is often closed until it is almost tight.

Mr. Constantine asked for more information as to boiler and admission pressures, and wished to know why funnel gases could not be utilised for heating feed-water. He desired to corroborate the last speaker's remarks as to the beneficial results obtained by partly closing the dampers.

Mr. Legros spoke as to the extreme accuracy of the calorimeter used, and, with the instrument before him, explained its *modus operandi* at length. He also explained that the breakdown of the means devised for priming was in great measure due to the fact that it was only determined upon at the last moment. A good deal had been said about the position of gauges, and in connection with that he would remind the speakers that speaking in that room was very different to acting on board ship. He thought the gas samples showed that the combustion had been very perfect.

Mr. Fothergill said he had not much to criticise in the paper, but would like to reply to one or two of the points raised. About the size of boilers he would ask them to consider what the ship did, and to bear in mind that with this vessel 3,000 tons was carried at an average rate of $8\frac{1}{3}$ knots on a coal consumption of 1·3lb. per indicated horse-power per hour. As regards forced draught, the results had proved that it was satisfactory. As to dampers, he regretted that Mr. McFarlane Gray did not quite catch his point, and, in spite of what that gentleman said, he still contended that the slight pressure did bring the gases more searchingly into contact with every nook and corner of heating surface than would obtain if the gases had a clean run through and got away more rapidly. Some members had objected to the machinery because of its being larger than necessary; this might be so, but then they had a reserve of power, and could work up to 900 h.p. easily if wanted. As to large funnel area, it was made so because, if the fan broke down, it would suffice for natural draught in the ordinary way. As to the use of forced draught, he could only say that it brought out the advantage of every foot of heating surface. The speaker directed his concluding remarks to showing from the tables of consumption that the results of the trials corresponded very closely with the results obtained in actual working.

Mr. Mudd, speaking on the size of the engines and boilers, showed that these could have been worked up to greater power, but was glad the trial had been made rather as one of ordinary working conditions than as a test of what power they could get. As to Mr. Burstall's remarks on the leakage, he could only refer to the previous trial of the chief engineer, extending over a period of nine days, and from which it was conclusively proved that the supplementary feed, when working with all joints tight, was not nearly so great as appears from the figures of this trial. Replying to Mr. Halpin, the speaker said that in his experience it did prove economical to "wire draw" the steam between the boiler and the engine, and thought that partly closing the stop valve did to a certain extent stop priming, when the priming partook of the nature of a "fog." As to Mr. Philip's inquiry for a diagram from the underside of the air pump bucket, he might at once say that such a diagram would be valueless, as there was no foot valve. Replying to Mr. Bruce's assertion that the results obtained were in great measure due to the quality of the coal consumed, he controverted such a statement *in toto*, and explained that these engines were their standard 900 h.p. type, and would give 950 h.p. easily.

Professor Kennedy called attention to the lateness of the hour, which prevented him replying at anything like length. He was sure the discussion had been expressive and satisfactory. He was glad to be able to inform them that Mr. Mudd had given him drawings of the engines, which would be reproduced in the *Proceedings*. He most strongly objected to corrections being made from one set of trials to another. All the trials were absolutely distinct, and as such he wished the different sets of results to stand each on its own merits. Speaking on the question of the large percentage of supplemental feed-water used during this trial, he must only say that it was abnormally large during the time it lasted.

The President said he did not think he need trouble the meeting with any remarks after the excellent discussion that had taken place, and brought the proceedings to a termination with the usual votes of thanks.

Mr. Boswell's paper, "On Some Details in the Construction of Modern Lancashire Boilers," was unavoidably held over.

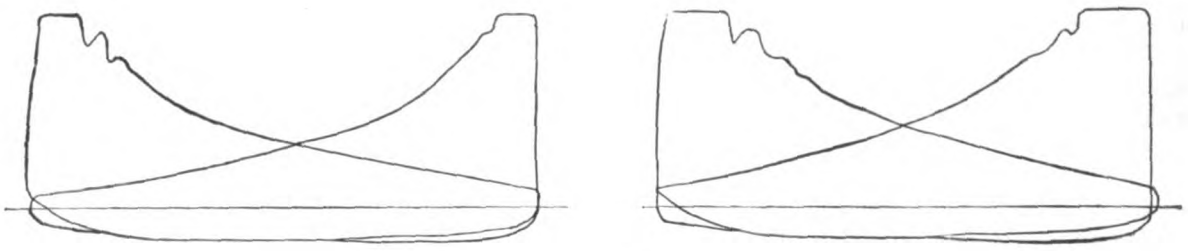

FIG. 16.

STEAM ENGINE GOVERNORS.*

(*Concluded from page* 436.)

THE size of a throttle valve is generally determined from the diameter of the engine steam pipe in which it is inserted, without regard to the conditions under which it is required to work; and since the steam pipes are often made considerably larger than necessary to pass the required amount of steam, with the supposed object of reducing the friction in the pipe, it follows that the passage through the throttle valve is often too large when fully opened. The result is that when the maximum load is put on the

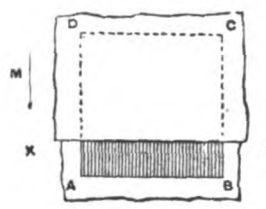

FIG. 17.

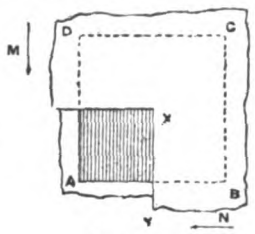

FIG. 18.

engine, the governor muff has only risen through a fraction, say one-quarter or one-fifth of its total lift, and only this small fraction of the total lift is utilised in regulating the engine. When, in such a case, a small variation—say an increment—in the load occurs, only an exceedingly small downward displacement of the governor will be required to counterbalance this variation, and the governor will generally overshoot the mark, since, owing to the additional friction which the governor mechanism encounters when changing from rest to a state of motion, the muff will not drop until the speed of the governor has been reduced to a lower point than corresponds to the increment of the load. The throttle valve is thus opened too far, and the speed of the engine is increased. The same action is then, of course, repeated in the opposite direction, and the governor is therefore caused to oscillate whenever a variation occurs in the load of the engine; and in this manner very irregular running of the engine is produced, and even greater variations of engine speed may result than would be produced with a less sensitive governor. If the throttle valve is too small, the governor muff must move over a long distance to counterbalance any small variation of the load, and unsteadiness is again the result. In such cases the limits of the engine speed may even greatly exceed the speeds corresponding to the extreme positions of the governor. If we suppose that we have two equally sensitive governors working under identical conditions, one of which, say A, is fixed upon a throttle valve having twice the area of the other, say B, then it is evident that, with a certain variation of load, the displacemement of B must be equivalent to twice that of A, and consequently the sensitiveness of the governor combination A will be double that of B. By extending this argument it will be seen that the sensitiveness of a governor and throttle valve combination varies as the size of the passage through the throttle valve.

These considerations point to the importance of determining the correct size of a steam engine throttle valve according to the conditions under which the engine is required to work; but this calculation offers some difficulty in the case of an engine which exists merely in the shape of a design, since the chief factors involved can themselves, in the majority of cases, only be determined by empirical methods In a completed engine the date required can be obtained experimentally by inserting a stop valve in the main steam pipe, and measuring the minimum opening of this valve with which the engine will run at the required speed with full load on, the governor being of course disconnected during the experiment. If then, it is required that the governor shall occupy the middle position with the same load on the engine, the area of the throttle valve must be twice as large as the opening of the stop valve determined in the experiment.

In the "Universal" throttle valve fitted by Messrs. Schäffer & Budenberg, in connection with their Four-Pendulum governor, as shown in Figs. 7, 8, and 9, the area of the passage through the throttle valve can be regulated by hand, and the sensibility of the governor combination can therefore be adjusted to suit different conditions under which the engine may be required to work. In order to illustrate the action of this apparatus, let A B C D in the accompanying Fig. 17 represent the opening of a throttle valve, and XX^1 represent a throttle slide, which is capable of closing the passage in the direction of the arrow M. Further, suppose that the throttle valve is open to the extent of one-quarter, as shown in Fig. 17, when the full load is thrown on to the engine. The lift of the governor will then be utilised to the extent of one-quarter. In the throttle valve under consideration, the opening A B C D can be closed laterally in the direction of the arrow N (Fig. 18) by means of a screw wheel. In Fig. 18 this valve is shown half closed, but the passage through the double valve is the same as in Fig. 17, the throttle valve being in this case open to the extent of one-half when the engine is working under the full load. It follows that in Fig. 17 the sensitiveness of the apparatus is twice as great as in Fig. 18, because in the former the rise of the governor muff required to effect the opening is only half of that in the latter case. In this way the same size of passage through the throttle valve can be made to correspond to different positions of the governor muff. It will be noticed that the motion of the governor muff is transmitted by means of a small connecting rod and lever to a rotary valve, which is provided with four square ports, working over corresponding ports in a cylindrical valve. This valve, which also serves as a stop valve, is adjustable by means of the hand-wheel in the direction of its axis, for the purpose of varying the width of the passage through the throttle valve, as previously explained. The entire lift of the governor muff nevertheless remains available for regulating the steam supply, and the lift of the governor can be utilised to any desired extent, even under a minimum load, by regulating the throttle stop valve. The apparatus can, therefore, be adjusted to suit all conditions of working. As an interesting feature in connection with this apparatus, it may be mentioned that the stuffing-box on the

THE ACKROYD-WILLOUGHBY SMOKE PREVENTER AND FUEL ECONOMISER.

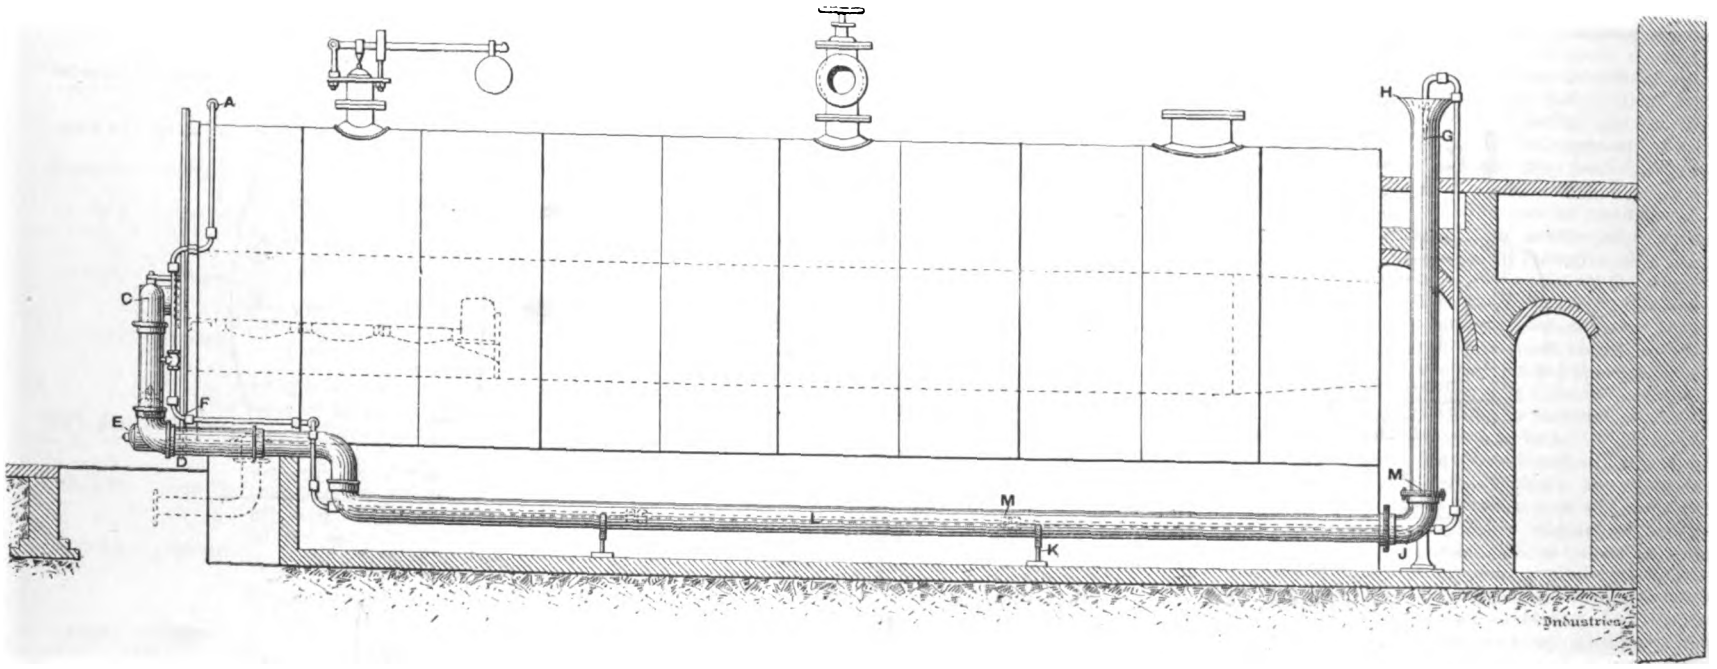

FIG. 1.—LONGITUDINAL SECTION.

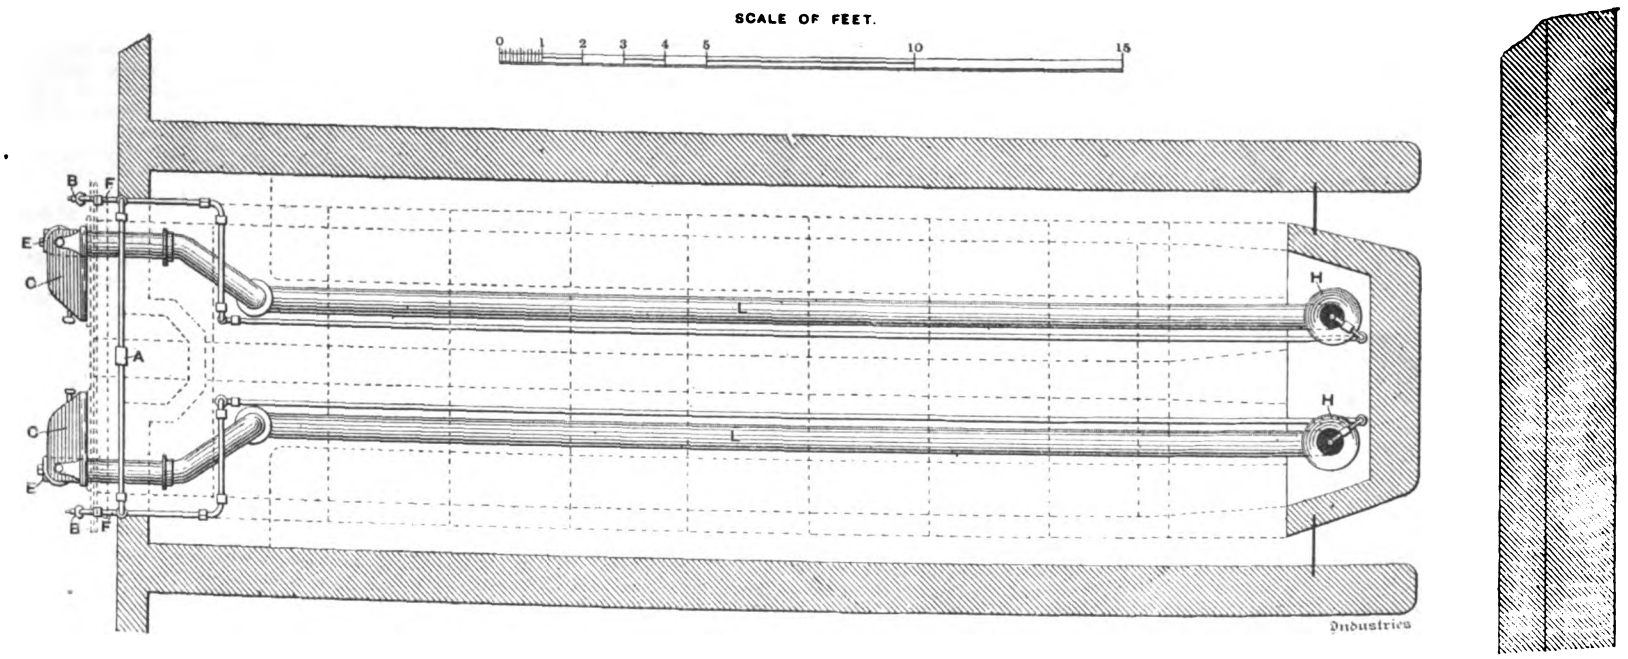

FIG. 2.—SECTIONAL PLAN WITH BOILER REMOVED.

throttle valve spindle is dispensed with, the joint being made by means of a conical valve, which is kept tight by the pressure of steam in the valve. The stop valve does not, of course, depend for tightness upon the rotary valve, but is provided with a separate seating for the purpose.

Although it is beyond the scope of this paper to deal with expansion gears, it may not be out of place to refer to at least one type of self-contained automatic expansion regulator represented in Figs. 14 and 15. This governor is used in addition to the ordinary slide valve, and is fixed upon the valve chest like an ordinary throttle valve governor. The action of the governor only differs from an automatic expansion gear in allowing the contents of the valve chest to expand with the steam in the cylinder during a portion of the stroke. The inner valve A is opened near the commencement of each stroke by means of the crank H and the rod S, which is connected with the slide rod of the engine. The valve is returned to its central closed position by the springs B, when it is disconnected from its connection with the crank H owing to one of the two curved arms C coming into contact with a balance lever Y, the position of which is controlled by the governor. The rotary valve is therefore released and the cut-off is effected at an earlier or later point of the stroke according to the position of the governor to suit the load on the engine. The apparatus can be made very sensitive, because the only work of the governor proper consists in regulating the position of the balance lever Y. The cut-off cannot take place later than half stroke, and if the rotary valve is not disengaged at this point it will close slowly when the eccentric makes the return stroke. Fig. 16 shows a number of diagrams taken under different conditions of load from an old single slide valve engine fitted with one of these expansion regulators by Messrs. Cochrane, Grove, & Co., Middlesbrough, and these diagrams serve to show how completely the engine is controlled by the governor.

In conclusion, I feel that the time at my disposal has enabled me to place before you but a smattering of an extremely wide subject, and I can only hope that I may, at least, have stimulated some little additional interest in, what appears to me to be, one of the most fascinating branches of an engineer's study.

THE ACKROYD-WILLOUGHBY SMOKE PREVENTER AND FUEL ECONOMISER.

THE problem of the prevention of smoke, particularly from the chimneys of mills and works, has for many years been a subject of deep interest to engineers. During the last fifty years many schemes of the most varied nature have been proposed for the removal of the great smoke nuisance, which is becoming such an important factor in causing filth and disease in our manufacturing towns and cities. Many of these schemes have been based upon a very imperfect knowledge of the conditions of the combustion of fuel, and were directed to what was then called "the burning of smoke." A better knowledge of the chemical conditions which govern the combustion of coal has led to better directed efforts in this direction. In new installations where suitable conditions for a fairly satisfactory combustion of fuel can be arranged—viz., ample chimney power, proper admission of air, and a sufficiently high temperature in the furnace—special apparatus has to some extent been rendered unnecessary. Schemes for smoke washing have also been proposed and experimented upon, but have not hitherto received acceptance. The majority of the various plans proposed appear to have been directed merely to the prevention of smoke, and not so much towards economy of fuel, consequently no general acceptance of any special apparatus has taken place. In fact, few, if any, apparatus has ever been brought before steam users which was easy of application to existing plant, cheap in first cost and up-keep, and free from complications and difficulty in working, while at the same time producing a sensible saving in fuel.

An apparatus which seems to fairly fulfil these conditions has recently been introduced by Messrs. Ackroyd & Willoughby, of Birkenshaw, near Leeds. From the illustrations, Figs. 1 and 2 above, and Fig. 3 on page 468, it will be seen that its principal feature consists of pipes L carried through the back flue and through

Digitized by Google

the bottom flue of the boiler. Air is taken in at the mouth of the pipes marked H, passes through the pipes L to the front end of the boiler, and delivers through pivoted fire-doors specially constructed to cause the heated air to impinge upon the fuel. Steam is taken from the front end of the boiler in pipes which are also carried through the bottom flue and up through the back flue to the mouth of the air pipes H, where they deliver steam through nozzles suitably arranged for the purpose. Steam is delivered through these nozzles for about three minutes after each firing. The result of this arrangement is that, during the time which elapses between each charge of the furnaces with coal, air is being delivered through these pipes at a temperature of about 440° Fahr. When the charge has been put on, the nozzles are opened, and the steam which is taken from the front end of the boiler and carried through the flues is delivered into the air pipes. Owing to the high point to which the steam is superheated in its passage through the flues, no trace of the effect of moisture on the air pipes is discoverable, and the heated air, when the jets are in operation, is delivered at a temperature of 451° Fahr. From the illustrations and description it will be seen that there are practically no working parts or gear likely to get out of order. It is simple of application, and can easily be adapted to any form of steam boiler. As will be seen, the action of the steam jets is under the control of the fireman, but in some cases it has been arranged, as can easily be done, to work them automatically. The apparatus, it would appear, where steam can be conveniently obtained, is equally suitable for furnaces, drying stoves, destructors, &c. An arrangement of this kind could also be easily applied to the boilers of steam vessels, and the prevention of smoke, particularly in regard to passenger steamers, would be, quite apart from the economy of fuel it would produce, a great boon, and largely increase the pleasure of a sea voyage. A considerable number of these smoke preventers have been already set to work, and recently most careful trials were made of the apparatus upon a boiler at Messrs. William Ackroyd & Sons, Lower Mill, Birkenshaw, near Leeds. The trials were made on two consecutive days, beginning at 9 a.m. and continuing until 5.10 p.m., with a stoppage of forty minutes during the dinner time. The weather was fine, with strong winds blowing from a westerly direction during both days.

The water fed to the boiler was accurately measured in a specially prepared tub which was filled to the level of the overflow and pumped empty each time. The actual weight of water which the tub could contain was ascertained by weighing, the temperature of the water being the same as during the trials. The pump used was a direct double-acting one, fixed close to the measuring tub, and all connections with the boiler, with the exception of the feed inlet and steam outlets, were blanked. The temperature of the feed-water was taken twice during the emptying of each tub. The height of the water in the boiler was noted at the commencement of the trial, the gauge glasses marked, and the water brought to the same level at the end of the trial.

The coal used was Burgy, from Spring Gardens Pit, Drighlington, near Bradford. It was of average quality, as shown by the analysis given in the accompanying tables. The calorific value of the coal was determined in a Thompson's calorimeter, and a mean taken of the results. The coal was weighed on a suitable weighing machine, 2 cwt. being weighed at a time. The fires were cleaned about 8 a.m., and again about 12.15, and the fires worked down at the end of the trial to the same thickness, as near as could be judged, as they were at starting. They were again cleaned at the end of the test, and the ash and clinker for the whole day weighed, after being cooled and kept dry. The firing was entirely by hand, the average intervals being from 12 to 15 minutes.

The temperatures of the atmosphere and the air in the pipes of the air-heating apparatus and of the flue gases were obtained by mercury thermometers, and readings were taken every half-hour throughout the trials. A special mercury thermometer, with the mercury under pressure of hydrogen gas, was used for obtaining the temperature of the flue gases at the back end of the boiler, to prevent mishap in case the temperature should exceed the boiling point of mercury.

The apparatus for drawing off samples of the flue gases for analysis consisted of a vertical tube having a slot about 4ft. long inserted in the flue at the back of the boiler.

The water carried over by the steam was directly determined by several experiments each day. The apparatus consisted of a sensitive beam scale, to one end of which was suspended a wooden box lined with zinc. The box was balanced, and 70lb. of cold water poured in. The temperature of the water was then carefully noted, and 4lb. of steam blown into the water from a pipe inserted in the main steam pipe under the boiler junction valve. The temperature was again read over, and the water allowed to stand for a corresponding length of time to that during which the steam was blown in, and the temperature again read to ascertain the loss by radiation. From these temperatures and the known weights of water, and water and steam blown in, the weight of dry steam was computed. The quality or dryness was found to be practically uniform throughout the tests.

The smoke observations were made over a period of two hours each day, and the character of the smoke emitted was defined by comparison with smoke-coloured diagrams. Particulars of the observations taken and the results obtained are given in the following tables:—

Results of Trial.

Particulars and Dimensions of Boiler and Chimney.

Type of boiler—	
Lancashire two flued, length 29ft., diameter 7ft. 6in., with 5 conical tubes in left flue, and 6 conical tubes in right flue.	
Flues—	
Gases enter bottom flue on leaving internal flues and return along each side flue to chimney.	
Heating surface—	
Total heating surface	941 sq. feet.
Fire-grate—	
Dimensions of fire-grates	7ft. by 2ft. 9¾in.
Total fire-grate area	39·37 sq. feet.
Area of air spaces	6·43 sq. feet.
Area of opening below grates	3·13 sq. feet.
Ratio of air space to grate area	1 to 6·12
Ratio of heating surface to grate surface	23·9 to 1
Steam space—	
Total steam space	275 cubic feet.
Chimney—	
Height of chimney above fire-grates	110ft.
Area of chimney at outlet	5·64 sq. feet.

Principal Observations.

	Apparatus Not in Use.	Apparatus in Use.
Date	March 3rd.	March 4th.
Time—		
Duration of trial	7·5 hours.	7·5 hours.
Air pressure—		
Mean barometric pressure	30·25in.	30·2in.
Steam pressure—		
Mean steam pressure above atmosphere by steam gauge	60·6lb.	60·4lb.
Temperature Fahr. corresponding to this pressure	307·7°	307·4°
Feed-water—		
Average temperature of water fed to boiler	173·5° F.	173·6° F.
Total weight of water fed into boiler	41,886lb.	39,688lb.
Average weight of water fed into boiler per hour	5,585lb.	5,292lb.
Water evaporated per sq. foot of boiler heating surface per hour	5·93lb.	5·62lb.
Coal and ashes—		
Total weight of dry coal fired	6,304lb.	4,946lb.
Average weight of dry coal fired per hour	840·5lb.	659·4lb.
Total weight of ash and clinker produced	1,193lb.	885lb.
Average weight of ash and clinker produced per hour	159lb.	118lb.
Temperature of air—		
Average temperature of external air	42° Fahr.	51° Fahr.
Average temperature of air inside at back of boiler-house	74° Fahr.	83° Fahr.
Average temperature of air passing into furnaces through ash-pit	42° Fahr.	51° Fahr.
Average temperature of heated air entering furnaces after passing through air pipes in flues	—	440° Fahr.
Average temperature of heated air passing furnaces after passing through air pipes in flues when steam jets on	—	451° Fahr.
Temperature of gases—		
Average temperature of furnace gases leaving boiler	491° Fahr.	487° Fahr.
Draught—		
Chimney draught by water gauge	·57in.	·6in.

Analyses of Furnace Gases and Coal.

Analysis of furnace gases, percentage volumes—		
Carbon dioxide	9·62	7·85
Carbon monoxide	1·48	trace
Oxygen	7·74	11·10
Nitrogen	81·16	81·05
	100·00	100·00
Or expressed in terms of gases and air—		
Gases of combustion	63·14	47·14
Surplus air	36·86	52·86
	100·00	100·00

Analysis of dry coal—	
Carbon	74·92
Hydrogen	5·30
Sulphur	4·20
Oxygen and nitrogen	7·50
Mineral ash	8·08
	100·00
Calorimeter tests of coal—	
Heat available in furnace per 1lb. of dry coal	12,730 th. units.

Principal Results.

	Apparatus Not in Use.	Apparatus in Use.
Air—		
Weight of gases produced per 1lb. of dry coal burnt	9·740lb.	10·493lb.
Weight of surplus air produced per 1lb. of dry coal burnt	5·171lb.	10·661lb.
Weight of H_2O vapour in air per 1lb. of dry coal burnt	0·095lb.	0·155lb.
Weight of steam from H_2O mixed with coal per 1lb. of dry coal burnt	0·041lb.	0·041lb.
Total weight of gas, air, and vapour per 1lb. of dry coal burnt	15·047lb.	21·35lb.
Temperature of cases—		
Increase in temperature of gases from temperature of external air	449° Fahr.	436° Fahr
Combustion—		
Weight of dry coal fired per square foot of grate per hour	21·35lb.	16·75lb.
Weight of dry coal fired per square foot of total heating surface per hour	0·893lb.	0·700lb.
Evaporation—		
Weight of water fed to boiler at a temperature of 173·5° per 1lb. of dry coal fired	6·64lb.	8·02lb.
Equivalent evaporation from and at 212° Fahr., assuming steam dry—		
(*a*) Per lb. of dry coal fired	7·11lb.	8·58lb.
(*b*) Per lb. of combustible burnt	8·77lb.	10·45lb.
Proportion of water evaporated into actual steam	96·48 per cent.	96·34 per cent.
Proportion of unevaporated water carried with the steam	3·52 per cent.	3·66 per cent.
Efficiency of boiler—		
Efficiency measured by thermal units transferred to the water	52·28 per cent.	63 per cent.
Increase of efficiency with apparatus in use		20·5 per cent.
Percentage weight of coal required to supply steam for the steam jets		3·5 per cent
Net economy of fuel produced by the apparatus		17 per cent.

Smoke Observations.

	Apparatus Not in Use.	Apparatus in Use.
Smoke—Black or dense, number of minutes per hour	15	0
,, Brown or medium, number of minutes per hour	5·5	2
,, Light coloured or faint, number of minutes per hour	3·5	15
,, None	36	43
Total	60	60

Summarising the principal results, it will be seen that the trials show that with the apparatus in use the evaporating efficiency of the boiler is increased 20·5 per cent., and the amount of smoke greatly reduced; in fact, dense smoke, which under the ordinary conditions of firing was emitted for fifteen minutes per hour, was entirely prevented, and the emission of brown smoke reduced from 5·5 minutes to 2 minutes per hour.

To the diminished weight of coal required when the apparatus is in use was added the calculated weight of coal required to generate the steam used during the periodic action of the steam jets. The amount of coal required for this purpose is about 3½ per cent. of the whole. After making this allowance, the results show that, with the Ackroyd-Willoughby apparatus in use, the cost of evaporating a given quantity of water is 17 per cent. less than under the ordinary conditions of firing, besides almost entirely preventing the discharge of carbon monoxide, and entirely preventing dense smoke—both very important advantages.

The arrangements were devised and the trials carried out by Mr. J. F. L. Crosland, M.Inst.M.E., chief engineer of the Boiler Insurance and Steam Power Company, Ld., 67, King Street, Manchester, aided by Mr. E. G. Field, an assistant engineer, and a staff of skilled inspectors, who have had an extensive experience in the conduct of engine and boiler tests. The flue gases and coal were analysed by Mr. H. Wood Smith, of Messrs. Wilkinson & Smith, analytical chemists, Manchester.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 12th May, 1891.

The Iron Market.—The situation continues to improve steadily, and prices have undergone a further augmentation. Bars are now quoted at 140s. 6d. and joists at 148s. 6d. per ton. This rise in price is in part owing to the fact that the forges are charging 128s. 6d. and 136s. 6d. respectively for the above classes of iron delivered in waggons at Paris, but at the same time there is a general understanding among the merchants which allows of the market being controlled better than heretofore. Only in the case of one or two exceptionally large orders an abatement of from 4 to 5 per cent. has been made. Old iron rails are in fair demand at 80s., and orders for castings are easily obtained at 112s. 6d. per ton. Messrs. Dietrich & Co., of Luneville, Meurthe-et-Moselle, have secured an order for 1,000 waggons from the Eastern Railway Company. In the same district the Pompey forges are very busy with about 5,000 tons of plates and angles, chiefly of Martin steel, for the Cosne bridge. In the North the market is very firm. The following are the quotations for the past week:—Bars, 124s. 6d. and upwards; joists with wide flanges, 132s. 6d.; 3mm. No. 2 sheets, 140s. 6d. to 145s.; and steel sheets, 160s. 6d. per ton at the works.

The Coal Market.—The situation continues unchanged. The prices in the North and Pas-de-Calais districts are as follow:—Manufacturing coal, 15s. to 15s. 10d.; screened, 17s. 6d.; coke, 15s.; and gas coal, 16s. 8d. per ton. In the Ardennes forge coal is quoted at from 12s. to 12s. 8d. per ton.

Centenary of the French Patent Law.—In view of the important centennial celebration of the establishment of the United States Patent System, which was recently held in Washington, it is interesting to note that the Society of Consulting Engineers and Patent Agents are taking steps to celebrate the centenary of the French law as regards patents for inventions, which was passed by the National Assembly on the 7th January, 1791, and which came into effect on the 25th May following. A committee, having at its head the President of the above-named society, has been formed, and efforts are being made to make the centennial celebration a success. It is proposed to hold the celebration on the 25th inst.

French Commerce in Iron.—The following figures show the movement in the French iron trade as regards the quantities of metal exported and imported during the first three months of 1890 and 1891:—

Imports during the First Three Months of

	1891.		1890.

BERLIN, 11th May, 1891.

Steam Tramways in Upper Silesia.—The construction of a line of steam tramways in Upper Silesia is again under consideration. A syndicate has now been formed at Beuthen, Upper Silesia, for the purpose of connecting Beuthen, Gleiwitz, Königshutte, and Kattowitz by steam tramways, and of serving the larger industrial towns which are situated in these districts. The same syndicate constructed last year a similar tramway line from St. Johann, near Biebrich, to Louisenthal, in the Rhine district, which has given very good results. It is expected that the line now projected will be equally successful.

Milk Preserving Manufactories.—Among the many manufactories for the preparation of sterilised milk in Germany, that of Mr. C. Drenckhan, at Stendorf, in Holstein, is one of the most important. The process employed is that of Mr. E. Scherff. The milk, after having been deprived of germs, is enclosed in bottles, which are sealed by the pouring of paraffin on the stopper. This firm also manufactures a milk powder, which is easily dissolved in water, and then has the appearance and properties of fresh milk. In order to prepare this powder, the milk is condensed and completely dried after the addition of a strong syrup.

Portland Cement Works.—The extensive limestone beds at Zscherben, near Halle, in Saxony, have been acquired by a company, which intends shortly to commence the construction of large Portland cement works near the railway.

The Iron Industry.—The Upper Silesian Iron Works are taking up the manufacture of small iron fittings for the permanent way of railways, which have hitherto been almost exclusively made in Westphalia. Bessemer pig iron from the Siegen district has recently been sold at £2 18s. 3d. delivered in Rhenish Westphalia. In consequence of this fact the Rhenish Westphalian Iron Union has again lowered its prices.

VIENNA, 11th May, 1891.

The Iron Market.—There was no improvement in the state of the iron market during the past week. There is an active business within the limits of the actual demand, which, however, remains below that of previous years. Speculative dealing has not given rise to larger purchases. Nevertheless the rolling mills are as well employed as usual in the manufacture of hoop iron and merchant iron. Plate rolling mills and foundries are also more briskly employed. There is a very large demand for wire and wire nails, and the manufactories find some difficulty in coping with the orders. The business in agricultural implements during the spring was satisfactory. Prices remain unaltered. The Bohemian Mining Company held its general meeting last week. The net profits amounted to £10,437, an increase of £2,646 over that of the previous year. The company pays a dividend of 5 per cent. The Prague machine works of Messrs. Britfeld & Co. have done a good business during the past year, and pay a dividend of 10 per cent. There was an important demonstration of working men in Vienna, Ostrau, and Bekés on the 1st inst., which, however, resulted in no disturbance.

The Coal Market.—Notwithstanding the fine weather of the past fortnight the coal market continues animated, and the Bohemian mines are well supplied with orders. The Ostrau mines have ceased to work since the 1st inst., in consequence of the strike, and the greater part of the coal for Vienna now comes from Silesia and Bohemia. The Koflach Railway forwarded more than 356,000 tons of coal from this district during the past working year, which shows an increase of 178,855 tons. The "Kronstädter Montan-Verein" is paying a dividend of 5 per cent.

Electric Lighting of Vienna.—The electric lighting of Vienna is chiefly carried out by the "Internationale Electricitäts Gesellschaft." The installation consists at present of 20,000 lamps of 16 c.p., and there are four compound steam engines, each of 600 effective h.p., working at 125 revolutions per minute. These engines can work either with or without condensation, and are used for driving directly an "A 8" Ganz alternator with a normal output of 400,000 watts. For service during the day a condensing steam engine of 300 effective h.p. drives an "A 7" Ganz alternator with an output of 200,000 watts. The total length of the cable laid by this company amounts to 28 miles.

BRUSSELS, 12th May, 1891.

The Iron Market.—Attention is now generally directed towards the strike, which may put a stop to the production of coal and cause coal mine owners to again raise their prices. The iron market is therefore depressed, and in a state of uncertainty. There is some demand for small material, but the sale of joists remains inactive. The supply of new orders is small, and leads to little business. The uncertainty of the market prevents arrangements being made for the future. There is an increase of the export to England. The statistics of the export and import trade show the extensive influence of the foreign demand on Belgian markets. There is a general decrease in the amount of metals exported, and it is expected that this decrease will be augmented, especially as regards iron. At the present time, steel works are more active than iron works. Constructing shops have also some orders, and are fairly well employed. The contracts for old rails for the State railways have been awarded as follow:—1,500 tons of Vignoles rails to M. Paul Strybos, of Antwerp, at £3 0s. 4d. per ton; 1,000 tons to M. Clabecq; 500 tons to the Providence and St. Fiacre Company. The contract for fishplates has been given to M. W. Daumont at £3 10s. 3d., and plates at £2 19s. 9d.

The Coal Market.—The strike makes an estimate of the state of the market very difficult. The export trade has slightly decreased, but internal trade has increased. There is an increased demand for coke, and many ovens which were blown out about two months ago are about to be blown in. The price of coke shows a tendency to rise, and to again reach 14s. 3d. per ton. Small sorts are quoted at 9s. 6d. per ton. This rise of prices must cause some uneasiness in the metal market. There is a good business in close burning coal for brickmaking, and some large sales have been effected from 6s. 9d. to 7s. 4d., according to the quantity. Coal for furnaces has been sold at 10s. 4d. per ton.

The Glass Market.—The state of the glass market has become still worse in consequence of the strike of coal miners. Manufacturers are accepting orders for America at a discount of from 80 to 84 per cent. Prices are therefore unremunerative, as it is impossible to reduce the net cost of production in consequence of the dearness of raw material, and especially of coal. Manufacturers have already asked for a decrease in the rates for transport, and an inquiry has taken place with regard to the rates on the State and the Grand Central Railways. The transformation of the "fours à pot" into "fours à bassin" has caused an increase of stocks which depresses the market. In consequence of this change in the furnaces, it is difficult to reduce the output, and manufacturers have therefore wisely agreed to blow out these furnaces during Sunday, and thus give the workmen a day's rest.

DÜSSELDORF, 12th May, 1891.

The Iron Market.—The prices of iron ores are as follow:—Raw spathic iron, 7s. 7d. to 8s. 4d.; roasted spathic iron, at 10s. 9d. to 12s. 3d.; Nassau hematite, with about 50 per cent. of iron, at 8s. 4d. Pig iron is quoted thus:—Spiegeleisen, 57s. 9d.; Rhenish Westphalian iron, No. 1, 52s. to 53s.; Thomas iron, 47s.; Siegen iron, 49s. to 50s.; Luxembourg puddled iron, 39s. 2d.; foundry iron No. 3, 47s.; German foundry iron, No. 1, 69s. 6d.; No. 3, 58s. 9d.; hematite, 69s. 6d.; Spanish foundry iron, delivered in the Ruhr district, 73s. 5d.; English pig iron, 56s. 10d. to 57s. 10d.; Spanish Bessemer iron, c.i.f. Rotterdam, 59s. 9d. to 60s. 8d.; German Bessemer iron, 61s. 8d. Ordinary bar iron, delivered within the nearest district, is quoted at 132s. 2d. Thin sheets are at 137s. 1d. to 147s. The prices are given per ton of 1,000 kgr., delivered at the works, unless otherwise specified.—Locomotive and waggon works are very well employed, and cannot supply all their orders.

The Coal Market.—The strike of the coal miners in this district has ended without any useful result being obtained, and nearly all the works are again in full operation. In Upper Silesia discontent continues among the workmen, and it is feared that it will spread still further. During the past week the "Königin Luise" Coal Mine, which is a Royal colliery, celebrated the hundredth anniversary of its existence. This mine now employs 9,000 workmen, and has a yearly output of 2¼ million tons of coal. It is thus the largest mine on the Continent. The following table shows the output in the Dortmund district during the past two years:—

	Number of Men Employed.	Output in Thousands of Tons.	Output per Head in Tons.
First quarter, 1889 ...	114,114	8,756	76·7
Third quarter, „ ...	114,148	8,997	78·8
Fourth quarter, „ ...	121,200	9,330	77·0
First quarter, 1890 ...	124,446	9,032	72·6
Second quarter, „ ...	127,049	8,524	67·0
Third quarter, „ ...	126,683	8,979	71·0
Fourth quarter, „ ...	132,038	9,033	68·4
First quarter, 1891 ...	134,642	8,917	66·2

From this table it is evident that in the course of two years, from the beginning of 1889 up to the strike in 1891, the number of workmen has increased by 20,000. The total output, however, has not increased at the same rate.—Prices in the coal market have not been properly adjusted since the recent strike, owing to the reserved attitude of both sides. There is some activity in the pig iron trade. Foundry coke is quoted at 15s. 8d. to 17s. 8d.; blast furnace coke at 12s. 9d. to 13s. 8d.; coke nuts at 16s. 8d. to 18s. 7d.

AMSTERDAM, 11th May, 1891.

The Eight Hours Question.—Sixty workmen of the Dutch Oil Factory at Delft have petitioned the managers to grant them, and all the other employés, "the boon of a working day of eight hours." The managers have sent a reply to the effect that they cannot entertain the suggestion, as they do not consider it to be for the advantage of anybody, least of all for that of the employés themselves. The managers say that they never shrink from adopting measures to the advantage of their workmen, even should such measures result in pecuniary disadvantage to the shareholders. If the shareholders do not like this, let them elect other managers, but the present managers declare that they are not going to give in upon such a question as this, which they deem a violation of the just rights of capital—rights as much to be respected as the rights of labour.

Tolls in Holland.—The Association for the Promotion of the Interests of Steam Navigation in Holland has made a strong protest against the passing of the Government Bill, now pending in the Lower House, for the better regulation of traffic and tolls upon roads, bridges, quays,

Digitized by Google

factories, and in harbours, belonging to the State. The memorialists point out that if the Bill be passed the present system of levying tolls will be perpetuated, and they proceed to demonstrate that the interests of the public will be best served by an entire abolition of all tolls, and the consequent freeing of every Government highway in the kingdom.

THE AMSTERDAM CAB COMPANY.—This undertaking has not done well in 1890. A gross profit of £13,356 only left an available net profit of £28, so that there is no dividend for the shareholders.

THE AMSTERDAM DRY DOCK COMPANY.—The directors of the Dry Dock Company in Amsterdam have issued their annual report, which states that 179 vessels used the dock last year, against 166 in 1889, and that the dock buildings are in a very good state. After providing for the necessary depreciation, there remains an available net balance sufficient to pay a dividend of £7 10s. per share of £83 6s.—equal to over 9 per cent.

THE ROYAL STEAM PACKETS COMPANY.—The report of the directors, read at the general meeting of shareholders, states that the combined service of the company between the islands of the Indian Archipelago, in accordance with the Government contract, commenced on 1st January, 1891, with twenty-eight steamships, thirteen of which were new vessels, built in Dutch yards, as provided for in the terms of the concession. Both the construction and the equipment of these steamers have given great satisfaction. The balance sheet, which was approved at the meeting, shows a capital expenditure of over £750,000.

STOCKHOLM, 9TH MAY, 1891.

THE STORA KOPPARBERGS COMPANY.—The "Stora Kopparbergs Bergslags Aktiebolag," which is one of the largest industrial concerns in Scandinavia, did a very large business last year, but the profits have not increased accordingly. The company's manufacture of steel and iron amounted during 1890 to 41,023 tons, against 33,515 tons during 1889 and 25,630 tons during 1888. The production of timber was, however, smaller last year than during the two previous years on account of the unfavourable markets. The figures in question are:—37,337 standards during 1890, 46,416 standards during 1889, and 39,268 standards during 1888. The sales from the various departments were:—

	1890.	1889.	1888.
Copper works ...	£61,171	£52,251	£58,841
Iron works	312,860	239,466	193,002
Saw mills	311,122	276,025	209,096
Total	£685,153	£567,742	£460,939

The amount of business was, consequently, 20 per cent. greater during 1890 than during 1889, and nearly 50 per cent. greater than during 1888. The net profits, however, are smaller than for either of the two previous years, owing to last year's unsatisfactory markets for timber and iron. The net profits for 1890, including £379 carried forward from the previous year, amounted to £52,336, against £84,045 for 1889 and £62,159 for 1888. It is proposed to pay a dividend of 6 per cent. or £32,000, to add £11,111 to the "disposal fund," to add £2,777 to the pension fund and £5,555 to the reserve fund, and to carry £893 to the present year. The reserve fund will then amount to £104,444 and the disposal fund to £166,666. The share capital is £533,333. The company's property is estimated at £1,689,227.

COPENHAGEN, 9TH MAY, 1891.

BACON FACTORIES.—The Danish bacon factories are, on the whole, not doing so well as they were a year or two ago, and several of them have by no means done well last year. The Skive Bacon Factory, which belongs to a Mr. Thompson from London, will probably be let to some agricultural societies in the neighbourhood.

THE STOVE QUESTION.—The Danish Industrial Society in Copenhagen has offered a prize of £27 for the best essay on the question of iron stoves for rooms. This is undoubtedly a very sensible competition, as stoves entirely take the place of fire-places in Denmark, and are therefore of great importance for domestic heating.

NEW STEAMER COMPANY.—A new steamer company has been formed at Rouders, Jutland, for the purpose of trading on the Chinese coast. A steamer of 1,000 tons has been ordered from Messrs. Burmeister & Wain's Shipbuilding and Engineering Company, Copenhagen.

PROJECTED NEW RAILWAY.—A railway is projected for South-Eastern Sealand and the island of Möen, with a bridge between Kallehave and Koster. It is proposed that the State should contribute £88,888 to the new line.

MADRID, 11TH MAY, 1891.

SPELTER WORKS IN SPAIN.—It has been known for a long time past that there are some blende mines in the centre of Spain. These mines are not rich enough to justify the expenditure of a large capital, nor are the ores sufficiently good to bear the expense of being carried to England or Belgium. Moreover, the combination of zinc producers in all countries lessens the chance of finding a sale for all the ores raised. A rich capitalist, who is well known as a lead miner, has lately been thinking of establishing spelter works in the coal district of Puertollano. It seems doubtful whether the project will be carried out, but the idea is good, as the ores are close at hand and coal is very cheap. Small coals for a lead foundry have recently been quoted at 4s. per ton delivered at the smelting works.

FIRE AT THE BILBAO SHIPBUILDING YARD.—A destructive fire broke out on the 1st. inst. at the shipbuilding yard of Messrs. Rivas-Palmer, now known as the Shipbuilding Yard Company of the Nervion, Ld. The fire seems to have been accidental, as no trace of incendiarism has been found after close investigation. There must, however, have been great neglect, as the fire ought to have been discovered earlier if a proper watch had been kept. The foundry, modelling shops, boiler-making sheds, and engineering machines have been destroyed, together with valuable work in progress. The works were insured in the Sun Fire Office, London, but the company will suffer a considerable loss, and much delay must take place before the company can utilise a great part of the capital invested. All work has been stopped for the present, and 2,000 workmen are out of employment. It is supposed that four months, at least, will be required before work can be resumed. In the unsettled state of the labour market a longer time may be necessary.

THE LABOUR QUESTION IN SPAIN.—The 1st of May passed without any serious disturbance. Although there are many agitators, who make a living by delivering speeches and inducing workmen to strike, workmen generally seem to think that their condition is not likely to be improved by these means. In consequence of this the movements in favour of strikes are too feeble and isolated to cause disturbances in any important trade. The workmen in the mining districts of Asturias and of Linares are well aware that nothing is to be gained and something may be lost by a stoppage of work. They did not even take a holiday on the 1st inst. Since that date some few strikes have taken place in different parts of the country, but a very small number of men took part in them. There was a small strike among the workmen of the rail-rolling mill of the Altos Company of Bilbao, where sixty-eight men have been turned out in consequence of their demand for increased wages.

COMMERCIAL BANK AT BILBAO.—Some of the principal industrial firms in Bilbao have started a new bank, with a capital of £200,000. Shares were subscribed for to an amount exceeding £1,500,000, and soon after the allotment were being sold at 35 per cent. premium.

ROME, 11TH MAY, 1891.

IMPORTS AND EXPORTS OF ORES.—The following tables show the amounts of the principal ores imported into and exported from Italy during the year 1889, and may be compared with the tables recently given, showing the production of ores and of the metallurgical and chemical works in that year:—

Imports.

Products.	Quantity (in Tons).	Imported from
Lead ores	2,421	Tunis, Spain, and France.
Coal	3,999,117	Great Britain, France, Austria, and Germany.
Petroleum	71,331	United States, Canada, and Russia.
Pig iron	191,082	Great Britain, Spain, and Austria.
Iron and steel	309,245	Great Britain, France, Belgium, Germany, and Austria.
Tinplates	8,475	Great Britain, Belgium, and Germany.
Copper and its alloys	6,340	Spain, Greece, and France.
Lead		
Alum and sulphate of alumina	1,487	Great Britain, France, and Austria.

Exports.

Products.	Quantity (in Tons).	Exported to
Iron ores	183,281	United States, Great Britain, Canada, and France.
Lead ores	7,439	France, Belgium, and Austria.
Copper ores	9,034	Great Britain and France.
Zinc ores	107,066	Belgium and Great Britain.
Sulphur	331,902	United States and Canada, France, Great Britain, and Germany.
Salt	110,145	Sweden, Norway, United States, Canada, and Brazil.
Asphalt	4,825	Germany, Russia, United States, and Canada.
Boric acid	1,943	Great Britain, United States, and Canada.
Graphite	1,376	Great Britain, France, and Belgium.
Mercury	394	Great Britain and Germany.

NEW YORK, 2ND MAY, 1891.

A LARGE DRAWBRIDGE.—A large steel drawbridge over the Arkansas River at Fort Smith, Ark., which has been constructed by the Union Bridge Company, of New York, was successfully tested recently by running a train of four Mogul locomotives over it. The bridge is 2,370ft. long and consists of twelve spans, of which one is a draw span 370ft. long. The structure will carry both highway and railway traffic.

A NEW POWDER.—A new high-power powder, made by the Du Pont Powder Works, has been tested recently with satisfactory results at Annapolis. It gave an initial velocity of 2,130ft. a second, with a pressure in the powder chamber of only 14·8 tons per square inch. The average powder now used gives only 2,080ft. per second with a chamber pressure of 15 tons.

A NEW DOCK.—A new dry dock is being constructed at Port Orchard, Wash. When completed the dock will be 600ft. long, 70ft. wide, and capable of taking a vessel of 30ft. draught.

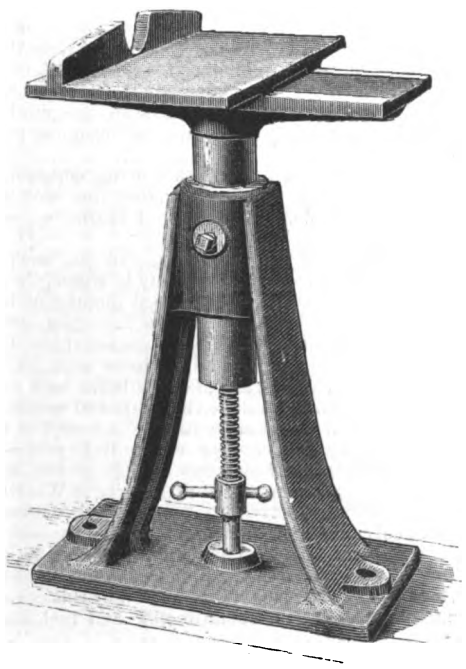
DEEP WELL IN WEST VIRGINIA.—An 8in. well, which the Wheeling Improvement Company is sinking in search of oil or gas, has reached, after several months of boring, a depth of 4,100ft. Both oil and gas have been struck in paying quantities, and, in addition, several thick veins of coal, layers of gold quartz, and iron have been traversed. It is stated that after a depth of one mile has been reached the Government will undertake the work, and continue the drilling as far as it is possible to go A complete record of all the drilling will be kept, which it is proposed to place in the Geological Survey's exhibit at the World's Fair in Chicago, and afterwards to preserve at Washington.

NEW CHEMICAL COMPOUND FOR TREATING COAL.—A new chemical compound, named "Kem-Kom," has been introduced by the Standard Coal and Fuel Company, Equitable Building, Boston, for treating coal and other combustible substances. The effect upon coal treated by this compound is to increase the heat, economise time and fuel, consume the smoke, destroy the soot, and materially reduce the quantity of ashes. It is claimed that by treating coal with Kem-Kom, from 15 to 30 per cent. of the coal is saved. It is further claimed that by using this compound on bituminous coal from 80 to 90 per cent. of the smoke is consumed, and that all the obnoxious gases are destroyed.

PHILADELPHIA, 1ST MAY, 1891.

THE READING TERMINAL RAILROAD.—Messrs. Wilson Bros. & Co., the architects and engineers of the Reading Terminal Railroad in this city, have awarded the contracts for the masonry work, consisting of foundations, 1,900 cubic yards; piers and abutments, 20,000 cubic yards; retaining walls, 26,000 cubic yards, to Messrs. Hart & Son and Messrs. J. J. Ryan, of this city. The cost of this part of the work is estimated at £100,000.

COAL MINING.—The National Board of United Mine Workers of America has issued an address to the members of the Order, setting forth that, in consequence of the aid furnished to the striking cokers in the Connelsville region, the funds which would otherwise have been available for a general strike on the 1st inst. were not sufficient for that purpose. It has, therefore, resolved to defer the eight hours movement and to continue the struggle in the coke regions to the end. The situation in the coke regions is at present more harmonious than it has been for some weeks. Those returning to work are not molested, and the Frick and McClure Companies claim large increases in their forces. The mine owners continue to insist that they will not submit, and think that at the end of the week they will be able to produce all the coke for which there is a market. In Pittsburg a strike among the coal miners is still probable; the river miners will not strike, but the railroad miners demand an increase in wages. At Springfield, Illinois, the miners are paid 2s. 7d. per ton, but the mine owners claim that they cannot afford to pay over 2s. 1d., and if the reduction is made the men will strike. It is stated that in Iowa all the coal miners, numbering 12,000, will strike to-day, and will not resume until the eight hours day is granted.



LARGE COMBINATION OF BREWERIES.—The Bergner & Engel Brewing Company, which is the largest in this city, is about to purchase the breweries of Messrs. Henry Mueller Brewery and of Messrs. Eble & Hirter, both in this city. In order to effect this purchase, the Bergner & Engel Company will increase its capital stock. The three breweries are valued at £1,000,000. This purchase will make the Bergner & Engel Brewery Company the third largest in the United States, the only larger ones being the Pabst Company, of Milwaukee, and the Annhauser-Bush Company, of St. Louis. The output of the Bergner & Engel Company for 1890 was 276,000 barrels, which is one-ninth of the whole output of the State of Pennsylvania. It is believed that the output of the combination for the present year will be about 400,000 barrels.

NAVAL MATTERS.—The cruiser "Newark," which has been in commission scarcely three months, has been ordered to undergo repairs, as there is a large leakage at the spar deck. It is not known whether this is caused by the strain to which she was recently subjected when docked, or whether the caulking was poorly done. Experiments are being made by the Navy Department with a new system of protection for gunners in exposed places on men-of-war. A peculiar kind of wire webbing, made up of interlocking steel spirals, which is exceedingly strong and flexible, has been prepared for that purpose.

Digitized by Google

A NEW BORING STAND.

The illustration given below represents a very useful appliance which is being introduced by Messrs. J. Sagar & Co., Wood-working Machinists, Halifax. This stand can be used in connection with numerous machines

having horizontal rotary spindles for boring purposes, for example, in connection with circular saw benches, planing machines, &c. The stand can be moved up or down to locate the hole as required, and the top table, which carries the timber, can be moved towards the boring bit to the necessary depth.

THE IRON AND STEEL INSTITUTE.

(*Concluded from page* 448.)

The first paper read on Thursday, the 7th inst., was by Professor Roberts-Austen, C.B., F.R.S., on

Certain Pyrometric Measurements and the Method of Recording Them.

This paper contained a description of Le Chatelier's pyrometer and the mode of applying it. A thermo-electric couple, consisting of platinum and an alloy of platinum with 10 per cent. of rhodium, is connected to a dead beat galvanometer. Two rays of light—one from the galvanometer mirror, the other from a fixed mirror—are thrown on to a photographic plate traversed by clockwork. The latter ray is interrupted periodically by clockwork so as to give a dotted line, while the other ray traces a curve which is the record of the temperature. The apparatus is calibrated, and this is easily done up to the melting point of silver, but the melting points of gold and palladium are not so certain. The temperature is proportioned to the current and to the deflection, and the curve is remarkably uniform. Very trustworthy results are attained by the use of this apparatus, and its applications are manifold.

In the discussion which ensued, Sir Lowthian Bell stated that never before had he had a satisfactory pyrometer. That of Siemens took several minutes, but this gave almost instantaneous results. He had one at work for determining temperatures over 100 yards from the recording instrument. Sir Frederick Abel made a few remarks as to the sharpness of the indications. Mr. Stead wished to know how it was that the couple was not destroyed by the formation of an alloy when it was inserted in the molten metal.

M. Le Chatelier, who spoke in French, further described the method of observation and its use for determining specific heats.

Mr. Charles Wood asked if the instrument would not be affected by deposits covering the wires, or by their change from oxidation or deterioration. The apparatus did not appear to be portable.

Sir Lowthian Bell explained that deposits would take the same temperature as the region in which they were placed. He had not enough experience of the instrument to say anything about deterioration. At his works, they carried the apparatus about in a kind of Sedan chair if they wanted it portable.

Professor Roberts-Austen stated that alloying did not interfere in the case of gold or palladium, but the wires had to be protected in the case of a volatile metal like zinc. There was no oxidation of the wires, but a carbide of platinum may be formed if they are not protected.

The next paper was by M. F. Osmond, and was a

Note on the Micro-structure of Steel.

Professor Roberts-Austen gave a brief account of this short paper, which describes some micro-photographs of steel exhibited last year at the Mining Exhibition at the Crystal Palace.

The Secretary read the third paper, which was by Dr. E. J. Ball,

On the Changes in Iron Produced by Thermal Treatment.

This was a continuation of a previous paper by the author on the same subject, and was intended to rebut M. Osmond's contention that his results were due to the fused oxide. With this object, bars of iron containing 0·1 per cent. of carbon and upwards were heated to various temperatures in reducing atmospheres. The bars were hardened and tempered, and were tested for tensile strength and magnetic permeability. The aim of the author was to show that there is a critical point at about 1,300° to 1,400° C. The details of some of the experiments were reserved pending the completion of other and more complete researches.

The discussion was opened by Mr. Wrightson, who drew attention to the similarity between this critical point and the temperature at which cast iron becomes plastic. In his experiments, published some time ago, he determined the changes in the volume of cast iron during heating and melting by watching the behaviour of a cast-iron sphere in a bath of the molten metal. Just before it melted it was so plastic that a steel rod could be thrust through it.

Sir Lowthian Bell asked if occlusion of gases had anything to do with this point.

Professor Roberts-Austen thought that allotropy in connection with iron and steel was the most important question of the day. Osmond had found two critical points at about 855° C. and 650° C., one molecular, the other chemical. He felt very disinclined to accept Dr. Ball's third critical point, and thought that it would be referred to the higher point in Osmond's determinations.

Mr. Snelus mentioned the crystalline formation as having been much overlooked in all these researches. It might be produced by vibration or by heat. He would again refer to the effect of segregation of impurities as having a bearing on the subject.

Mr. Hadfield said that he had recently experimented with a very pure iron containing 99·8 per cent. of metallic iron, and only traces of sulphur, phosphorus, and carbon. The tensile strength of the original forged samples was 22½ tons per square inch, but by heating to various temperatures, and subsequently air-cooling or quenching, the strength was lowered even to 17·9 tons. He quoted the details of these and other experiments to show that iron did not always change to the hard or β-state.

Professor Roberts-Austen explained that iron does not remain in this β-state unless carbon is present. He thought that Mr. Hadfield's experiments supported his contention.

Sir Frederick Abel agreed with the last speaker. It would, he thought, be of great advantage if results of this nature were published as soon as possible to prevent other workers going on the same lines.

The fourth paper, which was also read by the Secretary, was by Mr. T. Turner, on

Economical Puddling and Puddling Cinder.

This paper dealt with the different methods of puddling employed, and the chemical considerations connected with them. A large number of references to various authorities were given, and the whole question was dealt with at considerable length. The weight of the material charged, and the amount of fettling and fuel used, was gone into, and the action of the various impurities, such as phosphorus, was discussed. The author put forward his paper as a contribution to the discussion of the subject, and not as an assertion of his views.

In the discussion which ensued, Mr. Snelus said that he thought the author did not appear to have seen his paper on the Danks furnace, published in 1872, in the Journal of the Institute. This paper elucidated many of the points which now appeared as difficulties, and went fully into the question of the increase of weight of the blooms over the iron charged. He had proved that phosphorus is removed from the metal when it is in the fluid state.

Mr. Stead endorsed Mr. Snelus' views, and stated that his views on the phosphorus question had been misrepresented. The whole question of puddling was very difficult to treat, as so much depended on the work put in to the metal, an amount which was greatly influenced by the expectations of the puddler in the way of half-crowns. There is also great loss by oxidation after the metal is balled. Sir Lowthian Bell's papers ought also to have been referred to.

Sir Lowthian Bell said the paper was intended to promote discussion, but the author was certainly mistaken on many points. Such a paper as this ought to be printed and distributed early, so as to give them time to look into it well.

Mr. Bauerman thought that the paper was of interest, but it contained much that was old.

Sir Frederick Abel agreed with Sir Lowthian Bell, especially on the question of early publication.

The next paper, on

A Graphic Method for Calculating Blast Furnace Charges or Burdens,

was by Mr. H. C. Jenkins, and was read by the Secretary. The method consists of an adaptation of the graphic method of Professor Balling to a scale which can be used something like a slide rule. This consists of two scales at right angles to one another; one scale is mounted so as to slide in a groove parallel to the other scale. From the point where the zeros of the two scales intersect lines are drawn at an angle with the fixed scale, the angles being such that their tangents are equal to the ratios between the weight of silica to weight of base in the respective silicates which it is desirable to produce in order to form the typical fusible slags ordinarily met with in blast furnace practice. With such a scale it is a very simple matter to at once read off either the excess of silica in any ore, or else the amount required to properly flux off the earthy bases present. Examples are given of the application to some ores, and a simpler form of the rule is also described.

As no discussion ensued, the President stated that a paper by Mr. J. D. Weeks, on "The Coke Industry of the United States," was withdrawn by the author so that he might add some important information. The next paper was by Mr. W. H. Jaques, of the Bethlehem Iron Company, Pennsylvania, and late of the United States Navy. It consisted largely of descriptions of tests and trials, and parts of it would be read by the Secretary.

Recent Progress in the Manufacture of War Material in the United States.

This paper, of over sixty pages, contains a valuable record of the tests employed, and a discussion of the whole question of war material, and especially of armour plates. It should be read in conjunction with a paper by Mr. Biles (see *Industries*, Vol. X., page 291), on "Some Recent Warship Designs for the American Navy," recently read before the Institution of Naval Architects. The paper contains so much material that it is impossible to treat it suitably in abstract.

No discussion ensued, but M. Jules Garnier showed a photograph of a recently tested nickel-steel armour plate and some specimens of ferro-nickel containing 60 per cent. of nickel. He also described the method of eliminating sulphur from nickel and its alloys by melting them with basic fluxes.

After the usual complimentary motions the proceedings terminated.

PETROLEUM AND NATURAL GAS.

At a recent meeting of the Leeds Association of Engineers, Professor J. Goodman gave a lecture on "Petroleum and Natural Gas." The lecturer explained that originally it was thought that petroleum must be only obtainable in the coal regions, but later investigation proved this to be wrong, and that it existed in the form of carbides of metals. The nearer the surface the heavier the oils, those on the surface being actually solid, as bitumen, asphalt, and jet, while lower down heavy and dark oils are found, and from the deep wells light oils are obtained. The use of petroleum is of very ancient date. The natives used petroleum in America long before the white man ever set foot there, collecting it with material somewhat similar to blankets. Of course, this was surface oil, and it was used for its medicinal properties, the benzine and light oils being got away by evaporation. About 1849 Keir, a chemist, obtained some of this oil, and sold it at two dollars per pint as an embrocation. Later the demand became greater than the supply, and Keir discovered that by distillation he could concentrate the qualities, and he now obtained several dollars for minute quantities of his wonderful white oils. About this time a company was formed for the purpose of obtaining petroleum, and a small sample was sent to a professor in Boston, who, though he thought it was not satisfactory, found from analysis that it contained such valuable constituents that he reported most favourably,

Digitized by Google

with the result that much more money was raised, and more systematic work carried out. The same Professor, being caught in a shower of rain, stepped into a Boston chemist's for shelter. Here he noticed one of the bottles of Keir's oils, bearing a legend that it was obtained from the bowels of the earth. This led the Professor to study the matter, with the result that he pointed out with fair accuracy where oil would be "struck" by sinking wells. The first successful oil-well was made by a method similar to that adopted for sinking an artesian well. When it was sunk to a depth of between 400ft. and 500ft. the drill dropped some distance through a crevice in the strata. The men left work from the Saturday to Monday, but one of them visited the boring on the Sunday, and found oil just running over the top of the well. The news spread, and in a short time wells were sunk in all directions, the oil fever being equal to anything in the height of the gold fever. The price of petroleum has varied enormously from 5d. per barrel in 1861 to 48s. per barrel in 1864, the price in 1884 being 4s. per barrel. Up to the year 1884 the value of the yield of the oil-wells was £89,000,000. The lecturer here illustrated by lantern-slides the method adopted in sinking the wells. The ordinary time for sinking a well is fifteen to thirty days, boring being at the rate of 50ft. to 100ft. per day, the work being carried on day and night. The well is sunk first through a strata of loose drift, then through bed-rock, and then, at the depth of perhaps 2,000ft., the oil-bearing strata of sand or sandstone is reached. Frequently the oil will not flow from this, but a number of torpedoes are lowered down to the bottom of the well and exploded by dropping a weight from the top, and the oil is usually "struck" by this operation. The usual diameter of the well is 5½in., and the average cost is about £700 per well. About 10 per cent. are "dry holes," and will not yield oil. Natural gas is almost invariably given off from oil wells before petroleum, and it has been known to blow out the tool bars during sinking. It is said to have been found at a pressure of 900lb. per square inch, but this is open to question. It, however, is undoubtedly found at a pressure of 130lb. per square inch, and is used to drive ordinary steam engines, the gas being used like steam and the exhaust gas conveyed away and used for heating and lighting purposes. In Pittsburg, 20,000,000 cubic feet of natural gas per day is used for heating purposes, being equal to 1,100 tons of coal per day. An 8in. pipe will convey gas equal to a supply of 400 tons of coal per day. An interesting discussion followed the reading of the paper.

SHIPBUILDING NOTES.

On the 25th ult. Messrs. Short Brothers launched from their shipbuilding yard the steel screw steamer "Nerano," built for the Pinkney & Sons' Steamship Company, Limited, Sunderland. Her principal dimensions are:—Length, 320ft.; breadth, 42ft.; and depth, moulded, 28ft. The vessel is constructed of steel to the highest class in Lloyd's Registry under special survey as a spar-deck steamer with cellular double bottom for water ballast. Triple-expansion engines will be fitted by Messrs. W. Allan & Co., of Sunderland.

On the 25th ult. there was launched from the yard of the Naval Construction and Armaments Company, Limited, Barrow-in-Furness, the s.s. "Bonny," the first of three passenger and cargo steamships now under construction there for the British and African Steam Navigation Company, Limited, Glasgow. The vessel is specially fitted up for the African trade, and is built of steel to class 100A at Lloyd's on the three-deck rule for steam vessels. Her dimensions are:—Length, 328ft.; breadth, 39ft. 3in.; and depth, moulded, 24ft. 8in. The water ballast is in a cellular double-bottom tank The propelling machinery will consist of a set of triple-expansion engines, with cylinders 61in., 38in., and 23in. in diameter, by 42in. stroke. She will have two single-ended boilers, with a combustion chamber to each furnace. The working pressure will be 160lb. per square inch. The "Bonny" will be fitted with a complete installation of electric light.

On the 27th ult. Messrs. Richard & Henry Green launched from their yard at Blackwall "The Duchess of Devonshire," a steel paddle steamer of 200 tons gross. The leading dimensions are:—Length, over all, 178ft. 6in.; breadth, moulded, 20ft.; depth, moulded, 5ft. 3in. The engines, of the compound diagonal type, have been constructed by Messrs. John Penn & Sons, of Greenwich, and are of 385 i.h.p, with cylinders of 45in. and 22½in., and a stroke of 3ft. The vessel is built to the order of the Devon Steamship Company, of Exmouth.

On the 27th ult. Mr. John Lindsay launched from his shipbuilding yard at St. Anthony's-on-Tyne a wood screw steamer, the "Mary and Alice," intended for the general coasting trade. She will carry about 150 tons deadweight on an easy draught of water, and ship and engines have been built under special survey of the Bureau Veritas for their highest class. She will be fitted with a compound engine and steel multitubular boiler by Messrs. Hedley & Boyd, of North Shields. The vessel has been built to the order of Mr. Lindsay and partners.

Notices of Meetings.

THIS WEEK.

Royal Institution.—Friday, May 15th, at 9 p.m. Lecture on "Crystallisation," by Professor G. D. Liveing, F.R.S. Saturday, May 16th, at 3 p.m. Lecture II., on "The Artificial Production of Cold," by Mr. H. G. Harris, M.Inst.C.E.

Junior Engineering Society.—Friday, May 15th, at 8 p.m. Paper to be read: "Electrical Storage Batteries," by Mr. H. B. Vorley.

NEXT WEEK.

Royal Meteorological Society.—Wednesday, May 20th, at 7 p.m. Papers to be read: "On the Vertical Circulation of the Atmosphere in Relation to the Formation of Storms," by Mr. W. H. Dines; "On Brocken Spectres in a London Fog," by Mr. A. W. Clayden; "An Account of the 'Leste,' or Hot Wind of Madeira," by Mr. H. C. Taylor; "An Experiment Showing the Effect of an Electrical Discharge upon the Condensation of Steam," by Mr. Shelford Bidwell, F.R.S.

Chemical Society.—Thursday, May 21st, at 8 p.m.

PRICES CURRENT, 13th May, 1891.

Quotations at per ton, unless otherwise specified.

Tin: Straits	91	2	6	„	91	10	0
„ Australian	.....				.....		
„ English Ingots	94	10	0		.....		

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper continues quiet, with slack demand. Since our last report Chili bars have been weak at declining rates, but a steadier feeling is noticeable to-day, values being £51 to £51 5s. cash, with quiet business. Manufactured, £63 10s. to £64, "strong," according to specification.

Tin has continued flat during the week, and values have declined. Foreign to-day is quoted £91 2s. 6d. to £91 10s. cash.

Lead: Inactive, with values slightly easier.

Spelter is firmer, in consequence of strikes of Belgian workmen, and prices are likely to be dearer.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Chemicals: All qualities of carbolic acid continue very dull, although the best time of the year is now at hand. Benzoles have now a better tone. In sulphate of ammonia there is little business passing, but carbonate and muriate of ammonia are in fair demand for export. The depression in sulphate of copper is continued. Acetates of lead are firmer, but nitrate of lead is very quiet. Carbonate of potash and caustic potash are firm. Yellow prussiate of potash in demand. Oxalic acid more freely offered.

In our description last week of the duplex-compound locomotive for the St. Gothard Railway, we omitted to mention that the locomotive had been built from the designs of M. A. Mallet, of Paris, and that it is one of a class known as Mallet's Compound Articulated System.

We have received from Messrs. W. F. Dennis & Co., 11, Billiter Street, London, E.C., a copy of the third edition of their "Useful Tables and Data for the Assistance of Consumers of Wire." The present edition of the tables, which can be obtained either on card or paper, contains several additions and improvements.

Boyd's Map of the Mineral Resources of South-West Virginia (1891 Edition).—This is a very useful pocket map, which has been prepared by Mr. C. R. Boyd, geologist, of Wytheville, Va., showing the mineral resources and railway facilities of South-West Virginia. Besides giving the geological deposits of the district in different colours, such as iron, lead, zinc, manganese, tin, gold, &c., the map, which is on a scale of six miles to the inch, also gives much information concerning the location of the leading industries, such as steel manufacture, zinc smelting, and tobacco factories.

HOME INDUSTRIES.

LONDON, 14th May, 1891.

THE MONEY MARKET.—Money rates have been gradually growing harder with the growth of uneasiness regarding the European outlook. Gold is beginning to be attracted to this country by the advance in the Bank Rate and in the prices paid by the Bank of England for foreign gold coins. The foreign exchanges are going steadily in our favour, but notwithstanding this fact monetary prospects are very cloudy. For the moment the internal demands for currency reduce the Bank Reserve to a very low point, but the fear is that, even when this temporary pressure is over, money will still remain tight and grow more so. This week some stringency was apparent at the settlement on the Stock Exchange, heavy sums which have hitherto been at its disposal for the purpose of carrying stocks having been withdrawn by a large house which is preparing for demands from abroad. This has contributed to depress quotations, though no fresh influence was needed in that direction. The continuation of an uneasy feeling in Paris, as the result of the monetary crisis at Lisbon, reflects adversely on the London market, and as New York fails to throw off the influence of the steady gold shipments, the week has been one of descending prices and unrelieved gloom. Of course foreign securities have suffered most, including Rio Tinto copper shares, but it has been impossible to find any security which has not been affected.
